Mollison (*Agri. Ledg.*, 1895, No. 5, 53) observes:—The quantity and quality of the milk varies greatly by the nature of the food given. "The morning's milk is usually not so concentrated as the evening's milk, but on the other hand the morning yield is greater." But so constant is the composition and sp. gr. of milk that extreme variation from the standard must be accepted as denoting adulteration. The milk-sugar present in Indian milk to the extent of from 4.6 to 5.05 exists in a state of solution, and hence it very easily undergoes decomposition and is in consequence converted into lactic acid and the milk is then spoken of as sour. This fermentation at once becomes active when milk rises in temperature above 15° C. (59° F.). To ensure the preservation of milk it must therefore either be cooled below that temperature or retained at 50° C. The curdling of milk is the result of lactic fermentation, but this may be accomplished by means of organic or mineral acids or is simulated in cheese-making by the precipitation of casein by means of rennet. But rennet (the digestive agent of the stomach of a calf) has induced other changes than the mere precipitation of the casein, and its action is far greater than

that of lactic fermentation. This is the difference between sour milk and curds. But milk and cream are soured by a large number of different forms of bacteria which are communicated by the udders of the cow, the hands of the milkers, the vessels into which milked, or simply through permeating the atmosphere of the byre and the store-house. In many ways, therefore, they may be conveyed to and absorbed by the milk when kept in open vessels. The reader will find many highly important suggestions on this subject in an article recently contributed by C. Bergtheil (*Agri. Journ. Ind.*, i., pt. iii., 233). "Milk and Cream," he observes, "are naturally ideal media for the development of organisms, so much so that a sample of cream ripe for butter-making has been found to contain as many as 1,500,000,000 bacteria per cubic centimetre, far more than those found in sewage or any other natural material which has been examined. It, therefore, becomes a matter of great industrial importance to preserve milk from harmful fermentations, particularly those occasioned by pathogenic organisms."

sterilising.
Tainted Milk.
Fermentation
Germs
killed.

Sterilised Milk.—The greatest cleanliness is imperatively necessary, for even proximity to offensive smells will taint the milk. Some of the fermentative germs immediately start growing and commence the souring process, but these are instantly killed if subjected to a temperature of 50° to 75° C.; and should the milk also contain pathogenic germs (*i.e.* the germs of such diseases as typhoid fever) these will at the same time be destroyed. But other fermentative germs are latent and little affected by such temperatures as mentioned. In fact they are only killed either by continued boiling for some hours or by repeated heating and cooling. While left in the cool stage they are induced to assume the active condition, and are then killed by the succeeding heating. Repeated heating will thus serve the same purpose and more effectively (though more troublesome) than continued boiling, and it avoids the undesirable changes in flavour caused by prolonged boiling. When once completely deprived of the germs of its fermentation by heat, milk is described as sterilised or "pasteurised." Even if not protected it will now remain wholesome for some considerable time, but if kept in airtight vessels or bottles may be stored for months without undergoing any injurious change. The success of the Agra, Aligarh, Allahabad, Cawnpore, Darjeeling, Jabbalpur, Lucknow, Ootacamund, Poona, etc., dairy farms in supplying sterilised milk is being followed by many other institutions, so that supplies of good and safe milk may be now had in all the larger towns. The trade is a prosperous one with immense possibilities for the future.

Preserved
Milk (khir).

Preparation of.

Thickened
Milk.

PRESERVED OR CONDENSED (DESICCATED) MILK.—This is made by boiling fresh (whole) milk, to which sugar has been added, until it attains the consistence of syrup. This is called *khîr* (*khîr*) and in some parts of India *rabbî*, but sugar is not always added. Of Bengal districts, Tippera is spoken of as producing *khîr* of special quality. Sen, disc sing Dacca, says, "The flavour of this preparation of milk depends on (a) the quantity of milk boiled at a time, (b) the care with which the milk is stirred at the time of boiling, and (c) the nature of the heat applied. (a) To obtain *khîr* as white as possible, and possessed of the best flavour, not more than half a seer of milk should be boiled at a time. (b) All the time the milk is boiling it should be stirred with a wooden rod. Some prefer to stir with a number of rods. (c) A strong and steady heat should be applied. Tamarind wood is considered the best fuel for this purpose. *Khîr* of an inferior quality is sometimes made from fresh butter-milk." Banerjee remarks, "In order to get the *khîr* or thickened milk of a fine white colour, a little flour is added. In private houses arrowroot is used instead. When thick enough it is removed and allowed to cool, when it is ready for sale."

This is, therefore, a different substance from desiccated or strained *dahi*, although both are largely used by the sweetmeat makers. It has been recently upheld that the *khir* or *khova* (*mawa*) made from separated milk is good and marketable an article as that from whole milk, and hence the double profit in the *khir* and the butter. It has also often been urged that India might do a large trade in the production of condensed milk and in milk boiled down to a powder. Sweden, with its population of five millions, is believed to produce annually and export £2,000,000 worth of preserved and dried milk, a large share of which comes to India, instead of India itself exporting these preparations of milk. Thorpe and others have pointed out that the action of sugar in desiccated milk is preservative, but for this purpose 12 per cent. of the weight of the milk must be sugar. [*Cf.* Fleischmann, *The Book of the Dairy* (Aikman and Wright, transl.), 1896, 282-6; Thorpe, *Dict. Appl. Chem.*, ii., 615.]

Condensed
ilk.Action of
Sugar.Preserva-
tive Agents.

Reputed Preservative Agents.—In this connection also reference may be made to the passage above where Buchanan-Hamilton remarks that it is very nearly the universal practice to boil the milk immediately it is drawn from the cow, goat, etc. This fact cannot be reiterated too frequently. It will have been observed also that the earthen pots into which the animals are milked are often so nasty, to European taste, as to be regarded as destroying the milk. It may be explained that in many parts of India it is customary to smoke the milking-pots, but whether this is done to directly impart the smoky flavour or from the belief that it has a protective action, does not appear to have been investigated. When milk is to be carried for a distance it is placed in earthen pots with fairly large open mouths. These are swung over the shoulder by means of a bamboo, and a swift runner carries the milk to its destination. Within the mouths of such earthen or brass pots it is customary to find a few twigs or leaves—such as rice straw, date-palm leaves, twigs of *Cocculus villosus* or leaves of *Pedatium Murex*. The milkmen affirm these prevent the milk turning sour, but it is much more likely that their action is mechanical in preventing the milk from lapping over or being churned. *Cocculus* and *Pedatium* are known to have the curious property of thickening water, and may be added to the milk with the object of preventing the detection of water adulteration. Any one who will take the trouble to go to a railway station in the early morning and witness the arrival of Calcutta's daily supply of milk will not be surprised at the danger of direct and accidental adulteration, but rather at the rarity of outbreaks of disease being attributed to the impurities of milk. Speaking of Bombay experience, Lisboa (*Journ. Bomb. Nat. Hist. Soc.*, 1887, ii., 143) mentions the fact that arrowroot is employed to thicken milk which has been watered. [*Cf. Agri. Ledg.*, 1893, No. 17, 114-5; *Pharm. Journ.*, l.c.]

Smoked Milk.

Thickening
Water.

In concluding these observations on the preservation and manipulation of milk it may be added that boracic acid, carbonate of soda, carbonic acid, salicylic acid, oxygen and saltpetre, as also several other substances, are all spoken of as milk-preservatives, because they retard the action of the bacteria.

Chemical
Agents.

Separators.—Some few years ago (1889), at the suggestion of the Bombay Government, the Dairy Supply Company sent Mr. Howman to India in order to "ascertain by trial whether the cream separator is needed in India, and whether it can be profitably utilised in the manufacture of *ghi*. After an extended tour in several provinces, and after having made various trials, the following conclusions were published:—

eparators.

"1. *Tak*, a bye-product of *ghi*-making, can be prepared perfectly well from separated milk.

Tak.

"2. *Mawa* or *Khova*, which consists of desiccated milk sweetened with sugar, can be made from separated milk, and the cream saved for butter or *ghi*.

Mawa.

"3. As much *Ghi* can be made from separated cream as by the Native process." [*Agri. Ledg.*, l.c. 111.]

Ghi.

There are many designs or patterns of separators, but the principle is the same in all. They take advantage of the fact that cream or butter-fat is lighter than milk. By centrifugal force the liquid revolving thin a

cylinder at once, therefore, separates into cream in the middle and milk on the outside, and these two portions are conveyed away by separate pipes into the vessels placed for their reception. The milk can be separated immediately on its being taken from the cow. It is not required to be exposed in a large number of shallow basins; the milk as drawn from the cow may at once be placed in the separator. By a hand separator from thirty to forty gallons may be disposed of per hour. Obviously such results and advantages were of interest to every one in India, and it is no matter for surprise, therefore, that the new system attained almost immediate popularity. In June 1890 the late Mr. Ozanne, then Commissioner of Settlements and Agriculture, Bombay, obtained permission to employ Mr. Keventer, who had been Mr. Howman's assistant, and to purchase two separators. In a remarkably short time dairies, managed on the European system, sprang into existence here and there all over India. The fact of the double produce, (a) butter (*ghi*) and (b) milk, from which *marva* could be manufactured, was sufficient justification. All the larger towns of India are now rapidly being supplied with superior butter, also with sterilised milk and cream, conveyed in sealed cans or bottles. As might have been anticipated, however, the greatest progress has been made in the Bombay Presidency where the experiment originated.

Trade in Milk.—Absolutely no information can be given regarding the internal trade in milk. Within the past few years the foreign traffic has been officially recorded. In 1902-3 the imports of condensed milk were 1,490,154 lb., valued at Rs. 4,08,251; the following year, 1903-4, they had suddenly expanded to 4,137,066 lb., valued at Rs. 11,34,187; and in 1906-7 became 6,196,492 lb. and Rs. 17,68,347.

2. DAHI OR CURDLED BOILED MILK.—The names most generally given to thickened or coagulated or specially soured boiled milk are *dahi*, *dadhi*, *khoyá*, *mává*, *tyre*, etc. It is usually prepared by throwing boiled and partially evaporated milk into a vessel that has contained *dahi*, but has not been subsequently washed. At other times a certain quantity of *dahi* or some other acid substance is added to the boiled milk, or a vegetable or animal rennet is employed. Sen, speaking of Dacca, observes that, "To understand the method of preparation of *dadhi* of superior quality, we should remember that its formation depends on a fermentation of milk, and that milk undergoes a number of other fermentations besides that of *dadhi*, and that the particular fermentation it will undergo depends on the conditions under which this takes place. It is only when the milk is kept at a certain temperature, when a given quantity of *dadhi* of a particular degree of sourness is mixed with it, and when the extraneous germs of which the atmosphere is full are excluded from it, that the *dadhi* fermentation takes place properly." "A preparation of sugar, *batasha* and spices is sometimes added to the milk which is set to undergo the *dadhi* fermentation."

As a rule Muhammadans only will use animal rennet, and the vegetable rennets such as *Withania coagulans* are not very widely known. Hence *dahi* differs from curd, as prepared in Europe, in being practically sour

boiled milk, the fermenting agent being added when it is nearly cold. And the milk, being boiled immediately as obtained from the cow, contains all its fat or butter. In this form it is called *sara*, and if kept hot may be accumulated for some days till sufficient has been collected to form it into *dahi*. This, as Banerjei explains, is therefore *basa-dahi*. If butter be removed from the *dahi* by churning, the liquid that remains is butter-milk or *ghol-dahi* (*māthā, lassi*). But a top layer of the *dahi* may be simply skimmed off and used in the manufacture of butter. Hence there may be whole-milk *dahi* (*basa-dahi*), skimmed-milk *dahi*, as well as butter-milk (*ghol-dahi*). *Dahi* in the liquid state is largely consumed; hence its whey (*mastu*) contains all the milk-sugar and its curd (*chhena*) may or may not have embedded in it all the butter-fat. Whole-milk *dahi* thus contains too much fat to be made into cheese. It is, in fact, cream-cheese, and some localities such as Bandel near Hughli and Dacca in Eastern Bengal are famous for their cream-cheeses. When curds are intended to be prepared the acid or rennet is added to the hot milk. This is called *dud-chhena*, but *dahi* is often heated and allowed to cool in order to prepare imitation curds known as *dahi-chhena*. The whey (as it may be called) of *dahi* is separated by pressing the curd within a clean cloth, but if it be completely dried the *chhena* crumbles to a powder. All qualities of *dahi* and also of *chhena* are largely used in cookery and with *khir* constitute the chief ingredients of sweetmeats, which may thus be regarded as possessing all the elements of food and are not merely luxuries like the sweetmeats of Europe.

Sweetmeats.

Trade.—The trade in compressed (or partially compressed) *dahi* is very extensive, and within a radius around the chief cities immense quantities are daily conveyed by rail and road from the country to the towns, the curd being wrapped in damp cloths and deposited in open baskets. *Dahi* and *ghi* are therefore the products of greatest value in Indian dairy farming. Although every resident in India will readily admit that the traffic must be enormous, no sort of computation is possible of the total production of either the one or the other product.

Trade in
Dahi.

Internal.

But in conclusion it may be pointed out that the fermentative agents concerned in the coagulation of sour milk (not boiled), of boiled milk (*dahi*), of soured cream and of the various forms of curds (*chhena*), are probably all different and that success in the production of the manufactures named, to a far greater extent than as yet appreciated, depends on the use of the correct agent for each fermentation. [Cf. Sen, *l.c.* Dacca, 1889, 54-7; Banerjei, *Agri. Cuttack*, 1893, 128-30.]

Fermentation
Agents.

3. **BUTTER.**—Of India it may be said that two kinds of butter are known:—*nani* or the butter of fresh or only scalded milk, and *makhan* or the butter of soured milk (*dahi*). The former is held to be inferior and more difficult to prepare than the latter, but valued because the butter-milk obtained may be sold as *dahi*, and *khir* may even be made from it. Fresh milk is hardly ever set on one side to allow of the rise of the butter, and in consequence cream (*shar*) can hardly be said to be known in India. The article sold as cream (except that obtained by the modern cream separators) would more correctly be described as liquid (boiled) butter mixed with *dahi*. But the so-called Indian cream (as with the cream of Europe) is set aside to mature or ripen (as it is called), and when sufficient has been collected and matured it is churned and made into butter. observes that "butter is obtained by beating their cream into a substance like unto a thick oyl, for in that hot climate they can never make it hard, which though soft is very sweet and good." Fresh cream (that is to say whole milk) yields a smaller quantity and an inferior flavoured butter than matured cream. The peculiar flavour of butter is, in fact, very often a question of the method and degree of ripening that has been pursued. Moreover the best butter-makers lay stress on the necessity for the cream being repeatedly stirred during the ripening process. The time required depends on the temperature of the atmosphere. It will be sufficiently ripe in from 12 to 24 hours if the temperature average from 60° to 70° F., according to Fleischmann, but 90° F. according to Meagher and Vaughan; below 60° it will take 48 hours, but cream should never be allowed to fall below 55° F.

The study of the exact germs concerned in the production of recognised flavours of butter is by no means complete, but is engaging the attention of experts. In the near future pure cultures for the maturing of cream may be demanded but the subject is at present not understood, and both in Europe and in India empirical rules prevail. Cream is not pure butter-fat, but is a mixture of that substance floating in milk. The milk sours, the lactic acid precipitates the casein, and thus forms butter-milk. Butter, however, always retains some proportion of the sour curd mechanically mixed with it, and upon this depends the souring of the butter and its rancid flavour.

Churning.—Butter consists of the consolidated oil globules present in the milk. These are collected together and compacted into butter by various contrivances that may be called churns. As already fully explained, a small proportion only of butter is made in India from the milk as it comes from the cow. There is very little or no cream-butter made by the ordinary Indian milkmen, for the reason that the climate will not allow of the milk being set on one side until the cream rises to the surface. Recently, however, cream separators have been introduced at the larger centres and cream-butter has in consequence to a certain extent come into use. The bulk of the Indian butter is of a kind practically unknown to Europe, namely boiled soured-milk butter. It has been estimated that Indian milk yields butter at the rate of one pound to every 14 pints of best cow's milk or 9 pints of buffalo's milk; with separators very much smaller quantities will, however, suffice. The amount of butter nowadays made from separated cream is fairly large, and Bombay and Aligarh might be spoken of as the centres of the trade.

In *The Agricultural Ledger* (1895, No. 23) I have described the churns most commonly met with in India. The simplest contrivance of all is a wide-mouthed bottle or bamboo joint into which a quantity of milk is placed and shaken in the hand until the butter forms. Methods of preserving milk and of preparing from it special articles of human diet, that would wholly or partially withstand climatic tendencies, must have early become axioms of household economy in India. But the consequent development of this knowledge it would seem that the introduction within the liquid of a contrivance intended more fully to agitate it, than could be attained by shaking in a bottle, would be a natural and simple one, which might fairly well have suggested itself spontaneously to the most remote and diverse races. The first conception of this would most probably be a beater worked by the hand. The step from that to a rotatory whisk would be a direct and necessary one. But a vertical plunging action might not so readily suggest itself. This is the position in India. The rotatory churn is common, the vertical rare, though both forms exist. Whether or not the Aryans introduced the rotatory churn, the one most generally used throughout India,

may be left as a question for ethnology to solve. What can be affirmed of the people of India to-day is that the principle of that churn is known and practised all over the country, and among Aryan as well as non-Aryan races. The most frequent name for the churn is *mathani* (from *matha* to stir or churn). It becomes *māhal*, *māhab*, *mathan*, *matka*, *madhani*, *mahaindi*, *matki*, *mathni*, *math*, *māthāna*, *mathu*, etc. But every part of the contrivance has its own special name, and sometimes the complete apparatus takes the name of the agitator, at other times of the vessel in which the milk is churned. The simplest of all rotatory churns is that used by the ladies of the upper classes: it consists of a shallow basin or plate in which the milk is placed and a whisk made to rotate on the surface of the milk by its handle being rubbed between the hands. Vertical churns are usually made of bamboos and are most frequently used by the hill tribes.

Names given.

The Art of Churning.—Great skill is required in judging when the churning is complete. If stopped too soon much may be lost in the butter-milk; if too long protracted the butter may become greasy. The almost universal Indian practice of adding hot water, during the middle of the churning process, prevailed in some parts of Europe also, but it is now much condemned by scientific writers. [Cf. Fleischmann, *l.c.* 188.] After straining to remove the butter-milk the butter is washed once or twice in order to remove the curd and other impurities, as also as much of the butter-milk as possible. The butter is worked up, squeezed and beaten until it attains the desired consistence, and is then ready for the market. Water is, however, one of the chief adulterants of butter. As much as 25 per cent. may be present, though good-quality butter may sometimes contain as much as 10 to 15 per cent. As already observed, the presence of butter-milk impairs the lasting quality of the butter, and by turning sour makes it rancid. The melting-point of butter is a feature of some importance as it affords a means of readily detecting impurities. Indian butter, curiously enough, has a higher melting-point than European, a fact urged in favour of its great suitability to India. The food given to milch-cows also affects the melting-point of the butter. Cotton-seed, pulse meal, pea straw, ground-nut cake, etc., produce firm butter, whilst most other oilcakes soften it or make greasy butter. The cream from buffalo milk can be churned at a higher temperature than that of the cow and yet produce equally firm butter, and hence one advantage claimed for the churning of mixed cow and buffalo milk. If the mixture be thought to show too strongly the pale (bleached) colour of the buffalo or sheep butter, the colouring ingredient used should be added before churning. The best substance for this purpose is the pigment of the seeds of Arnotto (*Bixa Orellana*). Three ounces of the seeds soaked in 8 oz. olive oil, then strained, makes a good staining preparation. One teaspoonful to 40 lb. buffalo milk will usually suffice.

Addition of Hot Water.

Adulteration with Water.

Melting-point.

Buffalo Cream.

Arnotto.

Trade in Butter.—Very little of any importance can be furnished regarding India's trade in butter. The article is in daily use by the well-to-do of all castes and communities, but, India being an agricultural country, the supply is home-made. As an indication of the progress in modern dairy farming, it may be mentioned that in the *Administration Report on Dairy Farms in the Bengal Command for 1901-2* it is stated that 101,402 lb. of butter, 1,119,216 of whole milk, and 182,799 lb. of cream were produced and disposed of at the dairy farms of Allahabad, Jabbalpur, Lucknow, Cawnpore and Agra for that year.

Trade.

Production.

The returns of foreign transactions give, however, certain particulars of value. The *IMPORTS* of butter were in 1875-6, 76,658 lb., valued at Rs. 65,433; in 1885-6, 184,183 lb., valued at Rs. 1,65,335; in 1895-6,

Imports.

211,516 lb., valued at Rs. 2,43,439; in 1903-4, 277,112 lb., valued at Rs. 3,16,536; in 1905-6, 782,738 lb., valued at Rs. 3,12,510; and in 1906-7, 244,577 lb., valued at Rs. 2,66,636. To what extent this may be margarine is not at present known. The *EXPORTS* of Indian butter appear to have only begun to be separately returned in official statistics about the year 1890-1, when 1,118 lb., valued at Rs. 472, were sent to China and the Straits Settlements. In 1895-6 the exports were 152,462 lb., valued at Rs. 94,780; in 1905-6 they were 307,785 lb., valued at Rs. 2,16,614; and in 1906-7, 298,344 lb., valued at Rs. 2,09,292. It would thus appear that the export traffic is steadily improving. It goes almost exclusively from Bombay, and the countries that take the greater proportion of the Indian butter are Ceylon and Aden, and after these British East Africa, followed by the United Kingdom. This improved export trade is apparently the direct result of the recent endeavour to establish dairy farming on modern lines.

[*Cf. Ovington, Voy. to Suratt*, 1689, 324; Terry, *Voy. E. Ind.* (ed. 1777), 133, 198; *Paulus Egineta* (Adams, transl.), 1847, iii., 74-6; Sen, *l.c.* 56-7; Banerji, *l.c.* 129-30; Mollison, *l.c.* 59-63; Fleischmann, *l.c.* 106-99; Meagher and Vaughan, *l.c.* 93-108; *Imp. Gaz., l.c.*]

D. P.,
iii., 491-
Ghi.

4. **GHI (GHÉE) OR CLARIFIED BUTTER.**—*Manipulation.*—It may be said that the three great products of milk in India are *khîr*, *dahi* and *ghi*. The first two have already been disposed of. It is perhaps hardly necessary to describe the preparation of *ghi* (*neyi*) in great detail, since so much has already been said that has a direct bearing on the subject. *Ghi* is clarified butter. That is to say the butter is heated for about twelve hours or until the greater part of its moisture is evaporated. An oil is at the same time formed that rises to the surface, and the refuse (mostly casein) forms below as a sediment. Too much heating is said, however, to cause the *ghi* to assume an acid taste, while imperfect heating renders it liable to putrefaction. Great skill is thus required, but the *ghi* sold in the market has usually been undercooked owing to the loss in weight which takes place when fully cooked. Butter loses about 25 per cent. in the process of clarification. The yield of *ghi* from the butter of the buffalo is higher than from that of the cow. The boiling butter is allowed to be partially cooled, when the *ghi* may be decanted from the top of the sediment. The ordinary *ghi* of the bazârs is principally derived from buffalo milk. One quart of buffalo milk yields about 3 oz. of *ghi*, while the same quantity of cow milk may only afford about half that quantity, or with extra fine qualities, three-quarters of the *ghi* mentioned. *Ghi* from goat milk is very inferior owing to the disagreeable odour it possesses, while that of sheep milk is often spoken of as superior even to buffalo butter.

Definite Degree
of Heating.

Under-cooking.

Decanting.

Old Ghi.

Old and New Ghi.—So much has been written on the subject of clarified butter or *ghi* that a special volume might have to be written before even the more important historic and trade facts had been exemplified satisfactorily. *Ghi* is mentioned in some of the most ancient of the classic works of the Hindus. It is the *ghrita* of Sanskrit authors, and according to ancient medical opinion the *ghi* of cow milk is superior to that of buffalo or goat. As manifesting the antiquity of the knowledge in this article, it may be mentioned that in the *Periplus* (80 A.D., McCrindle, transl., 12, 113) *ghi* is spoken of as exported from India. It may thus be said to have been closely associated with the life and social customs of the Aryan races, but curiously enough has never been of much value with the people of Mongolian blood. Here and there all over India, especially along its

Classic Times.

mountainous frontier, certain races, such as the Kashmiris, are said not to eat *ghi* (Lawrence, *Valley of Kashmir*, 339). In the *Ain-i-Akbari* (Blochmann, transl.), 130) mention is made of the allowance to the State elephants. [Cf. also Jahangir, *Memoirs* (Price, transl.), 63, 71, etc.]

If carefully enclosed in skins while still hot it may be preserved for many years without requiring the aid of salt or other preservatives. It is somewhat significant, in fact, that medical writers should speak of *purana ghrta* (old *ghi*) as being superior to fresh. Dutt, for example, observes that *ghi* ten years old has a strong pungent taste and is of the colour of lac. "The longer this butter is kept the more efficacious it is said to prove as an external application. Clarified butter a hundred years old is often heard of. The richer Natives always have a stock of old *ghrita* of this description which they preserve with care for their own use as well as for distribution to their poorer neighbours." Fryer (*New Acc. E. Ind. and Pers.*, 1672-81, 137), in his description of Surat and a journey into the Deccan, speaks of "the granaries hewed out of stone" and of "several Tanks filled with butter of 400 years standing, prized by the *Gentiles* as high as Gold, prevalent in Old Aches and Sore Eyes, one of which was opened for my sake, and a present made me of its black stinking and viscous Balsom." Butter preserved in skins has been known to remain for many years without deteriorating very materially. It usually, however, dries and becomes almost like wax instead of changing colour and assuming the condition of the *purana ghrta* or medicinal *ghi* of the Hindus and the *rogghan* of Persian travellers.

Preservation.

Medicinal *Ghi*.

100 Years Old.

400 Years Old.

Roghan.

Food.—*Ghi* has been for many centuries at least an important article of food in India. Linschoten and most of the early travellers allude to its extensive employment in all forms of cookery. It is, in fact, used for all purposes to which butter is put in Europe—such as the cooking of meat, fish, vegetables, curries, rice, etc., or utilised in the preparation of sweatmeats, and is also eaten uncooked with bread and rice. With the poor it is a luxury for feast days, and in everyday life its place is taken by sweet vegetable oils.

Food.

Cookery.

Sweet Oils.

Adulteration.—The chief articles used in the adulteration of *ghi* are vegetable oils such as cocoa-nut, ground-nut, cotton, safflower, poppy, sesamum, niger and *kokam*. These are all harmless enough, though cheaper than *ghi*; but injurious oils are also used, especially *mahua*, *Satvadora* (*kakhan*) and castor-oil. Other animal fats, especially mutton, are largely utilised. Starches, such as rice, *bajra*, plantains, potatoes and yams, are frequently resorted to in order to thicken oily compositions. Impure or adulterated *ghi* is also often remade with milk or curd, to render detection difficult. The simplest method of ascertaining adulteration, and to purify the *ghi* at the same time, is to boil a given quantity, and when it is in a state of complete ebullition to dash cold water on it. The oil will rise to the surface and part from its admixtures. One of the most valuable papers on the adulteration of *ghi* is that written by Mr. Shroff, who states that the Bombay *ghi* trade is in the hands of a dozen merchants, and that adulteration is effected, not by the dairymen, but by the traders. The fats used are often most offensive and deleterious substances, at times even obtained from the carcasses of diseased animals. Numerous complaints have been made and even legal proceedings recently taken regarding the adulteration of *ghi*. In consequence the necessity for protecting the poor and helpless has been urged as justifying special legislation.

Adulteration.

Oils.

Starches.

Purification.

Legislation.

Packing.

Packing.—Formerly all *ghi* was packed in earthen jars (*matkas*), or for transport to a distance in leathern cases (*kuppas*), but in recent years old kerosene-oil tins or specially made tins have been employed.

Production.

Production and Consumption.—The chief *ghi*-producing tracts are the United Provinces, Bengal, Rajputana, Central India, and the Panjáb. It has been estimated that about one-fourth of the total population of India use 8 lb. per head per annum. Assuming these figures to be correct, this would represent a consumption of about 300,000 tons a year, or at a valuation of £45 a ton, say 13½ million pounds sterling. There are no data by which to verify these estimates, but as they stand they are suggestive of India's necessities in this direction.

Trade.

Trade in Ghi.—Prices.—No doubt by far the greater proportion of the *ghi* produced in India is consumed locally, and never appears either in the trade returns of internal nor of external traffic. It has been ascertained that the retail price of superior *ghi* ranges from 5d. to 1s. a pound. In the statement of *Prices and Wages* published annually by the Government of India, particulars are given of the prices of *ghi* in certain localities of Western India since 1855. These would seem to show *ghi* selling at a lower price than the figures just mentioned, but the difference between pure first-class and adulterated lower grade *ghi* is such as to render averages misleading. Still, the official returns as they stand manifest a considerable enhancement of price. Thus the average for all the Bombay centres in the quinquennial period of 1855–60 was 19·19 rupees per maund, and in 1903, Rs. 35·32; in Sind, Rs. 17·12, and in 1903, Rs. 33·28; in Central India and Rajputana, Rs. 24·3, and in 1903, Rs. 28·38. But taking the quinquennial average of 1871–5 as 100, Bombay is now 112; Sind 124; and Rajputana and Central India 110. In a further series of tables, *Prices and Wages* gives returns of the wholesale rates of *ghi*. These, for the year 1903 (and reduced for purpose of comparison to rupees and decimals of rupees per maund), would be as follows (in sequence of price):—Bengal, Rs. 34·3; Mysore, Rs. 34·1; Sind, Rs. 32·3; Madras, Rs. 31·4; Panjáb, Rs. 30·6; Berar, Rs. 30·4; United Provinces, Rs. 29·9; Central Provinces, Rs. 28·8; and Rajputana, Rs. 27·8. In a still further series of tables the prices of *ghi* are shown for selected centres such as Calcutta, Benares, Allahabad, Lucknow, Bareilly, Cawnpore, Meerut, Agra, Ambala, Lahore, Rawalpindi, Multan and Peshawar during the years 1875–6 to 1902–3. These are divided into buffalo *ghi*, cow *ghi*, and each of these again subdivided into 1st sort and 2nd sort. But the provincial averages just given approximate very closely (as the mean between all four classes in each centre), so that it is not necessary to furnish other estimates.

Enhancement.

Wholesale Rates.

Internal Transactions.

Internal Trade.—The total internal trade in *ghi*, as manifested by the railway returns, shows certain interesting peculiarities. The chief EXPORTING provinces are the United Provinces, Rajputana and Central India, the Central Provinces, Madras and Bombay (enumerated in order of importance). But it is significant that the exports of the United Provinces and of the Central Provinces have manifested extreme fluctuations for some years past. Thus from the United Provinces the exports in 1899–1900 were 236,718 cwt.; in 1902–3, 161,670 cwt.; in 1903–4, 140,617 cwt.; and in 1906–7, 164,222 cwt. The exports of the Central Provinces manifest a decline; thus in 1899–1900 they were 86,187 cwt.; in 1903–4, 63,079 cwt.; and in 1906–7, 42,665 cwt. So also the exports of

Centres of Supply.

Exports and Contractions.

Rajputana and Central India have shown corresponding fluctuations. In 1899-1900 they were 63,736 cwt.; in 1902-3, 151,451 cwt.; in 1903-4, 130,296 cwt.; and in 1906-7, 83,035 cwt. An expanding proportion of these Central India and Rajputana exports are consigned to the United Provinces, thus making up apparently the deficiencies of these provinces. A large percentage of the total exports are, however, consigned mainly to the port town of Calcutta, followed by Bombay, and appear again in the foreign exports from these towns.

Turning now to further provincial details, mainly IMPORTS: Assam, with its great herds of buffaloes, exports no *ghi* but draws upon Calcutta and the Province of Bengal for about 9,000 to 31,000 cwt. Bengal Province drains its foreign supply chiefly from the town of Calcutta. The United Provinces, as already said, import largely from Rajputana and Central India. The Panjáb annually exchanges about the same amount, namely from 11,000 to 34,000 cwt. Sind buys largely from Central India and Rajputana and Bombay, a quantity varying from 29,000 to 50,000 cwt. The Central Provinces are self-supporting, since they practically import little *ghi* but export a large amount. The traffic to and from Bombay Presidency is subject to extreme fluctuations. The imports in 1900-1 were 121,257 cwt.; in 1903-4, 10,376 cwt.; and in 1906-7, 10,348 cwt. The exports, on the other hand, were in 1900-1, 16,134 cwt.; in 1903-4, 54,157 cwt.; and in 1906-7, 97,166 cwt. Bihar takes little or no part in the traffic in *ghi*, but its imports are double those of its exports. Madras Presidency is self-supporting, since it imports very little, but exports very largely to its own ports and to Mysore and Bengal. It has already been observed that Rajputana and Central India export very largely, chiefly to the United Provinces, Sind, Bombay and the Panjáb, in the order named, but in years of famine or scarcity these States also import. Lastly, it is significant that Mysore with its herds of fine cattle exports no *ghi* to speak of, but is a fairly large receiving centre, the imports averaging about 14,000 cwt. derived from Coimbatore district in Madras.

Mysore.

The most noticeable feature of the Coasting Trade is the traffic, chiefly from Bengal (followed by Madras), to Burma, which in 1905-6 was valued at Rs. 17,01,609. [See *esa u*, p. 986.]

Tr. s-frontier Trade.—A fairly large quantity of *ghi* is brought across the land frontiers of India. The imports and exports by these routes during the years 1902-7 were as follows:—

Trans-
frontier.

		1902-3.	1903-4.	1904-5.	1905-6.	1906-7.
IMPORTS	{Cwt.	130,638	164,262	165,463	168,264	185,752
	{Rs.	53,08,589	64,05,129	71,93,973	75,86,410	90,73,421
EXPORTS	{Cwt.	1,588	2,135	3,007	2,342	2,749
	{Rs.	90,043	1,20,582	1,49,448	1,37,773	1,61,916

The import traffic is thus exceedingly valuable, and Kashmir stands unmistakably first. Lawrence observes, "It is by far the most important article of the export trade of Kashmir." The supply of *ghi* sent to India from that State was in 1906-7, 74,096 cwt., valued at Rs. 36,23,577. This may fairly be called a prosperous trade, since the figures just mentioned are nearly four times those of twenty years previously. Then come Dir, Swat and Bajaur, which furnished India with 50,544 cwt., valued at

Kashmir.

Dir, Swat and
Bajaur.

Nepal. Rs. 23,57,459 ; and lastly Nepal sent 42,765 cwt., valued at Rs. 22,09,334. The Kashmir *ghi* goes to the N.W. Frontier Province and the Panjáb ; the Dir, Swat and Bajaur also into the N.W. Frontier Province ; and the Nepal into the United Provinces and Bengal.

The re-exports of foreign *ghi* are unimportant, but have ranged from a valuation of Rs. 1,037 up to Rs. 2,07,185.

Foreign. *Foreign Trade.*—The IMPORTS being the least important may be disposed of first. This traffic is subject to extreme and sudden fluctuations. In 1876 the imports of *ghi* were valued at Rs. 2,76,395 ; in 1880-1, Rs. 16,486 ; in 1886-7, Rs. 7,03,432 ; in 1890-1, Rs. 4,13,299 ; in 1896-7, Rs. 4,28,432 ; in 1900-1, Rs. 10,71,024 ; in 1901-2, Rs. 4,17,476 ; in 1902-3 they were 21,370 lb., valued at Rs. 8,515 ; in 1903-4, 127,868 lb., valued at Rs. 50,722 ; and in 1906-7, 492,493 lb., valued at Rs. 2,13,861. The supply comes from Mekran and Sonmiani, Turkey-in-Asia, the neighbouring pastoral tracts of Southern Baluchistan, and recently from East Africa. It is consigned mainly to Sind and Bombay.

Consigned to
Sind and
Bombay.

Exports.

Turning now to EXPORTS, these for many years past have manifested a continuous expansion. In 1876-7 they were 1,004,661 lb., valued at Rs. 3,57,250. Twenty years later (1896-7) the figures were 3,672,349 lb., valued at Rs. 15,00,990, and during recent years for which returns are available they were in 1902-3, 6,418,045 lb., valued at Rs. 27,26,750 ; in 1903-4, 5,390,865 lb., valued at Rs. 22,90,825 ; in 1904-5, 6,097,917 lb., valued at Rs. 26,67,250 ; and in 1906-7, 4,884,252 lb., valued at Rs. 22,65,443. By far the most important centre is Calcutta, followed by Bombay, and the receiving countries may be said to be the Straits Settlements, Natal, Aden, Ceylon, Hongkong, Mauritius, British East Africa, Aden, etc. An effort was made some few years ago to foster the traffic in Indian produce sent to Australia, and *ghi* at that time attracted considerable attention. But the trade cannot be said to have materially expanded.

Chief Ports,
Calcutta and
Bombay.

Other Ani al Fats.—In conclusion it may be desirable to extend this brief review of the traffic in *ghi* so as to include all animal oils and fats, since these are often closely associated with *ghi*. The IMPORTS are Animal Oils, Butter, Ghi and Tallow. The traffic in the last mentioned is a large and prosperous one. In 1876-7 the imports of Tallow were 305,088 lb., valued at Rs. 62,671 ; in 1903-4, 2,352,224 lb., valued at Rs. 5,93,127 ; and in 1906-7, 4,125,744 lb., valued at Rs. 9,14,834. Next in interest are the Animal Oils, which in 1876-7 were 3,246 gallons, valued at Rs. 10,664 ; in 1903-4 were 389,256 gallons, valued at Rs. 4,45,217 ; and in 1906-7, 584,428 gallons, valued at Rs. 5,70,655. The lard and animal oils to some extent doubtless manifest the demands of the soap and candle works of India. The butter trade has been already noticed (p. 477), and need not be further mentioned. It is not known to what extent the imports of butter may in reality be margarine. But by adding the tallow, animal oils and butter to the *ghi*, the total imports of these substances were in 1903-4 valued at Rs. 14,05,602, and in 1906-7, Rs. 19,65,986. Similarly the EXPORTS may be briefly discussed. These are Animal Oils, *Ghi*, Lard and Tallow. In 1903-4 these were valued collectively at Rs. 25,52,340 (*ghi* being, as will be seen from the figures above, by far the most important article) ; in 1905-6 the corresponding total was Rs. 30,75,319 ; and in 1906-7, Rs. 23,84,765.

5. **CHEESE**.—Cheese as known in Europe can hardly be said to be made in India (except at the modern dairy farms under European supervision). Curd or *chhena* is prepared by boiling milk and throwing into it, while still very hot, some acid milk or other acid substance (such as lime- or tamarind-juice) or a vegetable rennet; after a time it in consequence coagulates. The curdled milk is put into a cloth and the whey (*mastu*) expressed or drained away, the result being a kind of soft cheese (often called in India cream cheese). Many localities are noted for their cream cheeses, such as Hughli, Dacca, etc. Sen gives the following account of the Panakona, Sylhet, or so-called Dacca cheeses:—"As soon as the milk is taken from the buffalo, it is put in an earthen vessel and rennet is mixed with it at the rate of a seer to a maund of milk. About two hours after the curd is broken with the hand and put in small quantities in shallow bamboo baskets known as *dalas*. Next day it is mixed with a little salt and repeatedly cut across with a knife, and each time the knife is passed through it the curd is pressed with the palm of the hand. This process is repeated for three consecutive days, and altogether 2½ seers of salt are used to a maund of curd. The cheese is then left to cure. This cheese is sent to Dacca, whence it is exported as Dacca cheese. A maund of milk gives 10 seers of cheese. The price of buffalo milk here is from Rs. 3-8 to Rs. 4 a maund. The whey is kept aside for a day or two, when the oily matter floating over it is removed and made into *ghi*, and the rest of it thrown away."

Lawrence says the Gujars and Pathans of Lolab make a kind of cheese they call milk-bread. He mentions an experiment in the manufacture of European cheese, and affirms that Kashmir might supply the British troops with good cheese and butter. At the Dairy Farms of Poona and Aligarh excellent cheddar cheeses have been produced (*Agri. Ledg.*, 1895, No. 5, 64). For cheese made from peas, consult Pogson (*Man. of Agri. Ind.*, 1883, 186); also see *Glycine* (p. 565). The following are the better known Indian vegetable rennets:—*Withania coagulans*, *Crotalaria Burhia*, *Leucas Cephalotes*, *Rhazya stricta*, *Streblus asper*, and apparently also *Carthamus tinctorius*.

Trade in Cheese.—The IMPORTS of cheese are much larger than might at first sight be realised, and seem on the whole to be increasing. In 1899-1900 they stood at 872,296 lb., valued at Rs. 5,34,278; in 1902-3 1,123,260 lb. and Rs. 6,18,577; in 1903-4 they had slightly decreased to 966,492 lb. and Rs. 5,34,158; but rose again in 1904-5 to 1,228,707 lb. and Rs. 6,29,274, and in 1906-7 to 1,275,111 and Rs. 7,04,487. Bombay and Bengal each receive on an average cheese to the value of 1½ lakhs. Sind takes about a lakh and Madras and Burma each half a lakh. About two-thirds of this supply is drawn from the United Kingdom, the balance from Holland, Belgium, Italy and Australia. The EXPORTS

Plain*, i., 263-5; **LEGUMINOSÆ**. A genus of tropical plants, mostly trees, that contains some 120 species, of which Prain figures and describes 86 as met with in South-Eastern Asia. Two of these (*D. Sissoo* and *D. latifolia*) are in India exceedingly valuable timber-trees, whilst the others are less important.

1. *.assa ica*, *Benth.*, is the *medoloo* of the tea planters (Watt and Mann, *Pests and Blights of the Tea Plant*, 1903, 141-4). 2. *.cultrata*, *Grah.*, *yendike* or *yindaik*, is a fair-sized tree common in deciduous forests throughout Burma. It is said to exude a red resin, to furnish a useful oil, and to be utilised by the Karenis for propagating the lac-insect. The heart-wood is blackish and ebony-like, often streaked with red. It is exceedingly durable, and is used for making wheels, agricultural implements, spear-handles, etc., and sometimes for carving. 3. *.lanceolaria*, *Linn.*, *f.*, is the *takoli*, *bithua*, *chakemdia*, *angaria*, *piri*, *chapot siris*, *gengri*, *dandous*, *tantosi*, *nal valanga*, *pedda separa*, etc. A deciduous tree of the Sub-Himalayan forests from the Jumna eastward, ascending the hills to 2,500 feet; also in Central and South India and Bombay. An oil is expressed from the seeds, and the leaves and bark are reported to have medicinal properties. The timber is said to be useful in building. 4. *.liveri*, *Gamble*, is the *tamalan* or *tabauk* tree of the *eng-daing* forests of Upper Burma (Wuntho and Bhamo). It attains a height of about 60 feet and girth of 4 to 6 feet. The wood is handsome, reddish, hard, close-grained, and takes a fine polish; is very like some of the South American rosewoods. It is largely used for axe-handles, dogcart shafts and other purposes for which great strength is required and is employed in the Royal Indian Marine dockyard at Mandalay for bushings to propellor-shafts, in place of *Lignum-vitæ* (*Guaiacum officinale*).

lack-
wood.

.l tifoli, *Roxb.*; Prain, *l.c.* 80-1, pl. 62; Thurston, *Ind. For.*, 1894, xx., app.; Koorders, in *Ind. For.*, 1894, xx., 282; Watt, *Ind. Art at Delhi*, 1903, 100, 126-34. The Blackwood or Rosewood of Southern India, *sitsal* (or *suet-sal*, white *sál*), *shisham*, *sissu*, *satsiyar*, *rute*, *ruzerap*, *tali*, *kalarukh*, *iti jitengi*, *eruvadi*, *yerugudu*, *jitangi*, *biti*, *thodagatti*, etc. A deciduous tree fairly plentiful from the submontane forests of Nepal, Sikkim to Chota Nagpur, Oudh, the Central Provinces, Central and Western India to Southern India. It attains its greatest size in the Western Ghats, south to Wynaad and Travancore, and ascends the hills to altitudes of 3,500 feet. Gamble (*l.c.* 250) says it is found in dry forests with teak and bamboo, as well as in moist evergreen jungles. It may reach a height of 80 feet and a girth of 12 to 15 feet, but it is of slow growth, especially at first. It is easily propagated by seed and is readily self-sown.

The wood weighs from 50 to 66 lb. per cubic foot, and sinks in water before being seasoned; it has a fine handsome grain, and is exported from the forests of Kanara, Malabar and Travancore to Bombay, Kathiawar, Kach, Karachi, London, Havre, Hamburg and Chinese ports. The planks when not well seasoned have a tendency to split longitudinally.

In India it is extensively used for furniture, cabinet-work, knees of vessels,

Blackwood
Furniture.

agricultural implements, combs, etc., for the vases and other ornamental articles of Trichinopoly, and for the finely carved chairs, tables, etc., which constitute the well-known blackwood furniture of Bombay. The art of making this furniture was introduced many years ago, and to this day it is mainly produced by the Portuguese inhabitants. Of late, popular fancy has discarded blackwood and good specimens of the furniture are said to be scarcely procurable. But most famous perhaps of all black woodwork is the Dravidian and Chalukyan carving of Madras Presidency and Mysore. If it is desired to darken the colour, this may be effected by rubbing the wood with oil until what is often spoken of as imitation ebony is produced.

Darkened
with Oil.

Outturn, Trade, etc.—The outturn of this wood in Madras, as recorded in the *Madras Forest Administration Reports*, was 2,374 cubic feet in 1900–1; 6,366 cubic feet in 1901–2; 11,808 cubic feet in 1902–3; and 16,182 cubic feet in 1903–4. These are the only available statistics of outturn, sale or export. In 1895 inquiry was made in London as to prices which might be obtainable for Indian rosewood. A report was subsequently issued by Mr. J. R. Royle, at that time Secretary of the Indian Section of the Imperial Institute. It was pointed out by the English firms consulted that the wood suffered from several disabilities. It is gritty and therefore much harder in the working than other cabinet timbers; it loses its bright colour and goes almost black after being cut and exposed; it is somewhat porous, and therefore absorbs the polish to a large degree.

Production.

Disabilities.

As a rosewood it is inferior to Brazilian, though superior to that of Madagascar or Honduras, but in England it has to compete with the cheap and usually reliable rosewoods sent from Jamaica. It would, however, prove specially useful where great width is required, as for example for table-tops, large carcass ends, and mouldings. Further it has to be remembered that rosewoods of all sorts, both for furniture and decoration, are very largely subject to the caprice of fashion, and at the time of the inquiry the European demand was very small. Gamble says that the usual London rate for good timber is about £10 per ton, and that there would seem still to be scope for greater activity in utilising the English market for the sale of at least the best pieces of Indian rosewood. In the reports mentioned above, one of the firms consulted thought that "the rate should not exceed 10d. to 1s. per superficial foot cut one inch," but that quotation, allowing 58 lb. to the cubic foot, would work out to about £23 per ton for picked, ready-sawn timber, a price thus considerably above the £17 10s. per ton reported to have been paid for a fine piece sent to London in 1878. On the other hand, some of the reports speak of Indian rosewoods as fetching an average of only from £5 to £8 per ton, but these low prices were for large lots not specially selected. Lastly, the quotations published by the trade for May 1905 were "Rosewood £5 to £12 per ton." "But it must be clearly borne in mind that rosewood of all grades is not at present popular." "At the present time East Indian is in fair demand and stocks are not heavy." In the *Indian Forester* (l.c. xx., app. 3) the selling prices, from the Madras forests, were given as from Rs. 20 to Rs. 75 per ton, according to distance from the coast, but in out-of-the-way places it could not be sold even at Rs. 10 per ton; from Travancore about Rs. 1–8–0 per cubic foot good quality (= about Rs. 58 per ton); of Bombay from Rs. 30 to 50 per ton. Logs for export should not be less than 24 inches in diameter, have the sapwood removed, and be exported in the round. The length should not, as a rule, be less than 15 feet, although shorter lengths find a market.

i oo, Roxb. ; *Notes on Changa Manga in Ind. For.*, 1895, xxi., 286–8; Prain, l.c. 57–8, pl. 34; Eardley-Wilmot, *Ind. For.*, 1898, xxv., app. The *sissoo*, *shisham*, *sisso*, *shisu-kát*, *tálí safeda*, *shín*, *nelkar*, *shewa*, *zagar*, *tanach*, *yette*, *karra*, *biridi*, *sínsapá*, etc. A deciduous tree of the Sub-Himalayan tracts from the Indus to Assam, ascending to 3,000 feet, but probably nowhere in India strictly speaking indigenous. Gamble remarks that it is often, however, gregarious on the banks of sandy, stony, torrential rivers. On higher lands it may grow, and grow well, though not gregariously unless planted. Cultivated and often self-sown on the plains of India. But even when the trees are growing close together the shade given is light, hence *sisso* is an important shade-

hisham.

tree with tea planters of Dehra Dun. The seed on germinating at once makes a great length of root compared to its growth above ground, a circumstance that greatly minimises the chance of its being swept away when spontaneous germination takes place within the sandy and stony beds of rivers.

Propagation. *Sissu* coppices well and reproduces itself freely from suckers. Artificially it is best grown from seed deposited in suitable positions, because transplantation is sometimes difficult and the young trees have to be protected till fairly established. It grows most luxuriantly on low-lying sandy tracts and has been successfully raised on irrigated lands, e.g. at Changa Manga in the Panjáb, at Shahdera near Lahore, etc. But it is reputed that the timber of trees raised under irrigation is of poor quality and subject to serious damage by fungi. When young the growth of *sissu* is very quick; it is said to attain 2½ feet of girth in twelve years, but as it gets older its growth gets slower. The full height of a tree is about 60 feet or so, and in girth it is rarely more than 6 feet. It is very successfully grown in Sind, and is said to be the best hardwood of the Panjáb.

Quality of Timber. **Growth Quick.** The wood is very durable, seasons well and does not warp or split. It is highly esteemed for all purposes where strength and elasticity are required, as, for example, agricultural implements, wheelwrights' work, frames of carriages, boat-building, etc. At one time it was extensively employed for gun-carriages, but owing to the limited supply of the timber it is now very little used for that purpose. It is one of the finest timbers in India for furniture and wood-carving, and is in regular demand all over the North of India. In Upper India the *shisham* wood (*D. Sissoo*) replaces very largely the rosewood (*D. latifolia*) of Western and Southern India. It attains its position of greatest importance in the United Provinces, the Central Provinces and the Panjáb, being replaced on the north by *deodar* and to the south by *sál* and rosewood. The wood-carving of Saharanpur, Farakhabad, Lucknow and Nagpur and the inlaid work of Chiniot, Hoshiarpur, Jalandhar and Mainpuri are largely on *shisham*. In Rajputana also, this wood is to a considerable extent employed by the wood-carvers, but for particulars of the methods of treatment and styles of carving the reader should consult *Indian Art at Delhi*, 1903 (103, 108-9).

Uses. **Gun-carriages.** **Important.** **Wood-carving.** Owing to the fact that the *sissu* very rarely grows straight, the timber is not of much use for beams though it is in much demand for knees of boats. It has been successfully tried for railway-sleepers, is an excellent fuel and makes very good charcoal, but it is too expensive to be utilised for these purposes. The wood is said to yield an empyreumatic medicinal oil, and the raspings of the wood are official, being regarded as alterative. Near towns the tree is largely lopped for fodder and the fallen leaves collected and valued as fuel by the sweet-meat makers.

Nepal
Paper.

AP N, *Linn.*; *Fl. Br. Ind.*, v., 193-4; Collett, *Fl. Sim.*, 1902, 435; Gamble, *Man. Ind. Timbs.*, 577; THYMELACEÆ.

There are two or three shrubs of economic value which belong to this genus:—1. *cannabina*, Wall., is the most important and may be spoken of as one of the best Nepal Paper Plants. It occurs on the temperate Himalaya from Chamba to Bhutan, at altitudes of 3,000 to 8,000 feet. It is the *setburwa*, *setburosa*, *satpura*, *dunkotah kaghuti*, *dhak chambot*, *chambot*, *barua*, *niggi*, *jeku*, etc. 2. *Involverata*, Wall., is the *chota aryili* and is met with in Sikkim, the Khasia hills and Ten serim, and in the countries where at all abundant it is used similarly to *cannabina*. 3. *ezereu*, Linn., is not indigenous to India, but is often mentioned by Indian medical writers and is perhaps imported and sold by the drug dealers. 4. *oleoides*, Schreb., is a small plant met with in the Western Himalaya from Garhwal to Afghanistan. It is best known by the following names—*kutílál*, *kanthan*, *gandalin* (*gandalinu*), *laghune*, *pech*, *pirkai buta*, etc. The roots are boiled and given internally as a purgative; the bark and leaves are also said to be used medicinally; the berries are reputed to induce nausea, and according to Brandis, a spirit is distilled from them in the Sutlej valley. It is just possible, therefore, that this may be the *Mezereon* of Indian medical writers. It is commonly reported that camels will not eat it and indeed that it is poisonous to them.

D. P.,
iii., 0.

5. *dgewort a ardneri*, Meisn.; *Fl. Br. Ind.*, v., 195 is a closely allied plant to the species of *aphne*, and one which would seem to be an even more important

source of Nepal paper than *D. cannabina*. It is a large elegant bush of the Central and Eastern Himalaya from Nepal to Bhutan, Manipur and Burma—distributed to China and Japan. It is known in India as the *kaghuti*, *aryili*, etc., and might be called the true Nepal paper plant. The *mitsumata* of Japan, and, according to Hemsley (*Journ. Linn. Soc.*, xxvi., 401), is *Edgeworthia chrysantha*. It is regularly cultivated in that country for its paper bark.

NEPAL PAPER.—Quite recently Stein (*Ancient Khotan*, 1907, 426) has announced the discovery of an actual specimen of Daphne paper, the date of which has been determined as the middle of the 8th century. This was found in the ruins of Endere and was examined both microscopically and chemically by Prof. J. Wiesner. The material was found to be a well-macerated fibre of the *Thymelaceae*, presumably *Daphne*. From the fact of no *Daphne* being known to occur in Eastern Turkestan, it has been inferred that the paper had been made in Tibet. [*Cf.* Wiesner, *Denkschr. Akad. Wiss. Wien., Math.-Nat.*, lxxii., 17-8.] It is thus permissible to regard this as the oldest recorded sample of what is commonly spoken of as "Nepal Paper." But even during the beginning of the 19th century, Nepal did not produce enough Daphne paper to meet the demands of India. Buchanan-Hamilton (*Acc. King. Nepal*, 1819, 232-3) tells us that the local supply did not suffice and that Nepal had to import both the paper and the raw material from Tibet. Kirkpatrick (*Acc. King. Nepal*, 1811, 80) speaks of one of the two species seen by him as being the paper-plant of Tibet. It would thus be more correct were the paper in question called "Tibet Paper," and this change in name would be in direct accord with the discovery narrated by Stein. [See Paper and Paper materials, p. 862.]

Nepal
Paper.

Nepal Imports.

It is perhaps hardly necessary to repeat that there are two important plants from which the so-called Nepal paper is made:—(a) *E. Gardneri* and (b) *D. cannabina*. Perhaps the earliest account by a botanist of this paper-material is that given by Wallich, who figures and describes three species and tells us that *Edgeworthia* was regularly cultivated in Nepal for its paper-yielding bark. In 1837 Lord Auckland, while Governor-General of India, called for further information, and various reports were in consequence prepared and submitted to the Government of India. Atkinson and other more recent writers repeat the statement that the Bhot country sends to this day large supplies into Nepal. Still, however, no material progress has been made, and Nepal paper is no nearer than it was a hundred years ago to becoming a commercial commodity. In fact it may be doubted whether any bark fibre is ever likely to be of value, unless for very exceptional purposes; it is too expensive as a modern paper-material. Nepal, Kumaon and Sikkim are the chief regions where India's supply of the so-called Daphne or Nepal paper is obtained. The reader should consult Broussonetia, p. 186, and Paper materials, p. 868, for further particulars. [*Cf.* Wallich, *As. Res.*, 1820, xiii., 383-90 and 3 pl.; Lace, *Journ. Linn. Soc.*, 1891, xxviii., 312; Morris, *Cantor Lect. in Journ. Soc. Arts*, 1895, lxiii., 938; Dodge, *Useful Fibre Plants of the World*, 1897, 146; Kanjilal, *For. Fl. U. Datura.

istory.—The vernacular names given to the species of this genus can hardly be said to distinguish the various forms that exist. The Sanskrit names

Doubtfully
Indigenous.

dhustura or *dhathura* and *unmatta* mean "insane," and hence might have been given to an introduced plant (on its properties being recognised); in fact might be upheld as not necessarily involving an ancient knowledge. The better known vernacular names are either derived from the above or have meanings in the languages to which they belong that denote the well-known properties of the drug. As met with in India the species of *atura* have the appearance of introduced plants. They frequent waste lands near human dwellings or invade the borders of fields or cover abandoned cultivation. They do not exist as individual plants that take their own positions in a blended vegetation, but appear as invading cohorts and here and there become so abundant as to exterminate all other plants. No form of *Datura* exists, in fact, under such conditions as to justify the emphatic opinion that it is indigenous to India.

The White-
and the
Purple-
flowered
Forms.

It is customary to read of "the white-flowered *datura*" and of "the purple-flowered *kala-datura*" as if these conditions implied specific distinctions. Not only so but many writers affirm that the purple-flowered form is a more deadly poison than the white, but that belief doubtless rests mainly on the theory of signatures. Any of the Indian forms may have white or purple flowers, may have single or double flowers, and may have thorny or smooth fruits. How far the chemical properties of these plants are affected by cultivation, by soil or by climate, it is at present impossible to discover. One thing, however, is certain, that the *Daturas* have been, and to some extent are still, cultivated plants, so that the differences recognised between the so-called wild plants of one region and of another may be due to their being more recent escapes from a special cultivation. Possibly all the Indian forms constitute but one or at most two species. *D. Stramonium* might be called the type of the temperate and alpine series and *D. fastuosa* that of the tropical assemblage.

Temperate
and Tropical
Forms.

Ancient
Knowledge.

Beverages.

But if the *Daturas* are only introduced plants, their properties have in India been fully understood for many centuries. The account published by Garcia de Orta in Goa during 1563 of the criminal uses to which they are put, might be reprinted a statement of the nefarious practices of to-day. So also the investigations of the Hemp Drugs Commission might be summarised as the discovery that if taken in moderation *bhāng* is harmless, but when mixed with *Datura*, that intoxicant becomes most reprehensible and even dangerous to life. Moreover the seeds are known to enter into the composition of certain alcoholic beverages and render the consumers of these literally mad. Some years ago I witnessed a remarkable process of making *arak* (country spirit) potent. A few seeds of *Datura* were burned on a charcoal fire, an empty earthen pot was held the while over the fumes. When full of smoke *arak* was poured into the jar, the result being its adulteration with the active principle of *Datura* in a form that would most likely escape detection by any ordinary process of examination (see *Spirits*, p. 1047). The extent to which *Datura* seeds are used criminally in India can be readily judged of by the perusal of the annual reports of the medical examiners to the various Governments and Administrations of India. These literally teem with particulars of *Datura*-poisoning.

Cri al Uses.

The following particulars of the chief forms may assist in their recognition:—

t r f t o, *Linn.*; *Hummatu*, Rheede, *l.c.* 47. The *kala dhathurā*, *khunuk*, *toradana*, *ūdah-dhathurā*, *karu-umate*, *nalla-ummetta*, *kechubang*, etc., etc. A small shrub found all over the tropical parts of India; the most common and abundant species. The capsule is retained in a nodding attitude and opens irregularly near the apex. There are said to be several recognisable varieties of which *D. alba*, *Nees* (the *saféd-dhatura*) is that most frequently mentioned and most highly approved medicinally. It has the flowers often creamy-white, but is doubtfully separable from the type.

Medicinal Fo

tel, *Linn.*—This is found chiefly on the N.W. Himalaya and the mountains of the Deccan.

Temperate
Form.

tr o i u, *Linn.*—Is met with on the temperate Himalaya from Baluchistan and Kashmir to Sikkim. The capsule is erect and deeply four-valved. This seems far more likely to be the white *Datura*

of medical writers than *var. alba* above. It is described as the *tattur* of the Panjáb and the *kachola* of Afghanistan. Lawrence (*Valley of Kashmir*, 1895, 77) mentions that Kashmir exports the seeds largely to the Panjáb and that they fetch Rs. 5 a maund. The *var. Tutula* appears to be the plant of which the dried fruits (strung on thread) are sometimes imported into India from Persia. These imported fruits are sold under the name *yharbhúli* in Bombay and *maratia mughú* in Madras. Poisoning from eating *tatuleh* is recorded in the *Kew Bulletin* (1889, 275-8; 1896, 233).

The MEDICINAL uses of the species of *Datura* centre chiefly in their poisonous property and in the pernicious and criminal advantage often taken of these all too prevalent plants. Barry points out that the seeds of *Datura* may be mistaken for those of *Capsicum*. Reduced to a powder they are criminally mixed with food and can often only be detected through the microscopic structure of the fragments of the seed-coat that may be discovered in the food or the contents of the stomach.

Carrot.

abitat.—A native of Kashmir and the Western Himalaya at altitudes of from 5,000 to 9,000 feet. It is also commonly held to be a native of Europe (except the extreme north), of Abyssinia and North Africa, of Madeira and the Azores, and of North Asia eastwards to Siberia and Kamschatka. Throughout India it is cultivated by the Europeans, mostly from annually imported seed, and by the Natives from an acclimatised if not indigenous stock. In many parts of the country a greenish-white carrot is preferred as being very hardy and productive. This rises some two or three inches above the soil, is a coarse root which possesses little of the flavour of the European carrot, but is able to withstand the extreme heat of summer, and may be raised in some parts of the country throughout the year. It thus produces a return at seasons when other tubers or roots are scarce or not available. This is particularly the case in Bihar (Patna) and some parts of the United Provinces.

Distribution.

Indian Form.

istory.—Sir George Birdwood (*Memo. Carrot for Famine Relief in N. Ind.*, 1896) gives a detailed and learned account of the history of this plant. This occupies many pages, and can hardly be abbreviated without greatly lessening its value. The carrot appears to have been regularly used in India from fairly ancient times. The Emperor Baber (*Memoirs*, 1519 (Leyden and Erskine, transl.), 1826, 347) narrates his having eaten a dish of fried carrots. In the *Ain-i-Akbari* (Blochmann, transl., 63-4, 67) mention is made of "wild carrots" (*shaqaql*) and of cultivated carrots. Terry (*Voy. E. Ind.*, 1655 (ed. 1777), 91-2) speaks of the good carrots of Surat, and Fryer (*New Acc. E. Ind. and Pers.*, 1672-81, 119) makes special mention of those of the Deccan. While much reliance cannot be placed on names of plants as historic evidences, it is significant that throughout the languages of India, indeed from Central Asia to Cape Comorin, there should prevail in every language a name for the carrot (*gáger*, *gájar*, *gázara*, *garjara*, etc.) which seems to have come from a common source. To that name is frequently added a further word meaning "root" or "tuber." Thus in Tamil it is the

History.

gajjara-kellangu. The derivation of the Latin name *carota* and of the French *carotte* is probably direct from the Greek *karoton*. The Sanskrit *garjaru* originated the Persian *zardak* and the Arabic *jegar*. In fact, the evidence of cultivation would lead to the inference that the carrot spread from Central Asia to Europe, and if so it might be possible to trace the European names from the Indian and the Persian. Indeed the carrot seems to have been grown and eaten in India while in Europe it was scarcely known as more than a wild plant. In Anglo-Saxon it was *weal-mora*, *wald-mora*, *walck-mora*, *clap-wype*, but it was confused with the parsnip till about the end of the 11th century. These names recall the German *mohre*, *moraha*, the Russian *morkov*, the Sanskrit *mula*, *mulaka*, and the Kashmiri *mor-mujh*, and they all denote "root."

Cultivation.—Bengal.—A writer in *Indian Gardening* (Oct. 27, 1898) says in his experience (in Chumparan) the seed should be sown broadcast early in November. Of the imported varieties the Large White Vosges and White Belgian succeeded best. The crop continued to yield till the end of May. Other writers in the Northern and Central portions of the province speak of sowings in August and the crop coming into season in January and February. Mukerji (*Handbook Ind. Agri.*, 1901, 357) observes that the carrot has a special value as a nourishing famine food and fodder. The Red Mediterranean variety grown at the Cawnpore Experimental Farm seems to be the best. The Yellow Mediterranean is most highly spoken of as a cattle food. The yield of the White Mediterranean carrot is almost equal to or even higher than that of country carrots, but the roots are hard, coarse and insipid. When grown without manure the country carrot gives a much larger yield than any of the European varieties. The proper time for sowing carrot seed in the plains is from September 15 to October 15. It is best to sow in drills and ridge the drills after the plants have appeared, then thin out. The quantity of seed used is 8 to 12 oz. an acre. The yield comes to 200 to 500 maunds per acre, if loose soil near the village be chosen, deeply cultivated, well pulverised, weeded and irrigated. The seed had better be mixed with wood-ashes at the time of sowing, and unless the soil is quite moist, water should be poured in the drills immediately after sowing. [*Cf. Firminger, Man. Gard. Ind.* (ed. Cameron), 1904, 166-7.]

United Provinces.—Duthie and Fuller (*Field and Gard. Crops*, 1893, pt. iii., 9) say the area occupied by the carrot is not separately estimated in the agricultural returns, but the average under carrots, turnips and radishes for the three years ending 1889-90 amounted to 41,463 acres. The carrot is generally sown in September or October; the roots are ready for use after two months, and may last for three or four months. A loamy soil is preferable. Under favourable conditions an outturn of over 200 maunds is possible. At Cawnpore 60 maunds is said to be the average, but at Basti only 33 maunds. The bazar price in ordinary seasons is from 8 to 16 seers an anna.

Panjáb.—Brief notices are made of carrot cultivation in the Panjáb. In Jhang it is said "the zamindar's food consists largely of carrots" (*Replies Famine Comm.*, 228). In Sialkot (*Gaz.*, 68) the carrot is spoken of as grown all over the district, and the superior European kinds are little known.

Bombay.—Of Gujarat it has been said that carrots of two kinds are cultivated—"the long-rooted" and the "blunt spindle form." They are grown at various times in different parts of the province, generally in garden beds from seeds sown broadcast, but are sometimes transplanted from nurseries during the *rabi* season. They take three months to mature,

though by nipping off the heads growth may be prolonged. The young plants are also taken up when half grown and sent to market. The produce is from 5,000 to 10,000 lb. an acre. The carrot is also grown in Gujarat from August to May, and the crop gathered four months later. In Kach it is much raised as a field crop. In Poona and Khandesh the carrot is cultivated very largely on black soil, with the help of manure. Of Ahmednagar a curious process is reported of obtaining carrot seed: When the crop is ready the husbandman cuts off a thick slice from the crown end of the carrot. This he puts two fingers deep below the soil in any place where there is a liberal supply of water. After a few weeks the roots produce a vigorous flower stem, the seed of which is gathered four or five months after having been thus transplanted. There are accordingly two crops in the year—one, the root produced from the seed, the other the seed produced from the root (see *Raphanus sativus*, var. *caudata*, p. 912). In the Deccan, according to Woodrow (*Gard. in Ind.*, 1889, 340), the carrot may be grown as a culinary vegetable where the rainfall is not over 25 inches annually, during the rainy season. Large sowings for fodder should be made in October and November, and if late rains are favourable good crops may be grown on a deep retentive soil without irrigation.

Yield.

Method of
Seeding.

Mysore is stated to produce a very good quality of carrot, but in Madras and Burma the root seems to be raised only as a garden vegetable.

ysore.

Food and Fodder.—The so-called root constitutes an important vegetable in the markets frequented by the European community. Although certain classes of Hindus in Bengal object to eat the carrot, on account of some fanciful resemblance to beef, still the Natives of India, as a whole, are year by year taking more kindly to it. At the same time it must be added that, though by the Muhammadans and certain Hindus the carrot has been cultivated for ages, it is only within recent years that it has become a recognised article of diet. By certain classes the young carrots are used only as pickles. By others "the root is first boiled in water, then squeezed out and cooked in *ghi*." In Europe it has become a recognised article of cattle food. Carrot-tops afford a useful fodder, and the contention that the roots might be resorted to in times of famine is strengthened by the fact that the tops would be of value to the cattle. [*Cf. Agri. Ledg.*, 1898, No. 12.]

Vegetable.

Cooking.

Seed.—The seed yields by distillation a medicinal oil. [*Cf. Taleef Shereef* (Playfair, transl.), 113.] In the Hemp Drugs Commission Report (iv., 415) mention is made of the seeds constituting one of the spices used in flavouring *bhāng*. Lawrence (*Valley of Kashmir*, 67) says carrot seeds are employed to mix with caraway. The chemical constituents of the root are crystallisable and uncrystallisable sugar, a little starch, gluten, albumen, volatile oil, vegetable jelly, malic acid, saline matters, lignin and a peculiar crystallisable, ruby-red neutral principle, without odour or taste, called *carotin*. [*Cf. Pharmacog. Ind.*, ii., 136.]

Indian Species and Varieties.—The account given in the *Dictionary* of this very difficult and imperfectly known genus of edible plants was written in 1888. It was subsequently arranged by the Government of India that a concentrated effort should be made to secure fuller and more accurate information. Collections of live tubers, accordingly, began to arrive in 1894, and continued to be received during the subsequent years. It was agreed that the yams as received should be cultivated in the Royal Botanic Gardens, Calcutta. They are therefore being systematically studied. A preliminary and unofficial report has already appeared, written by Prain and Burkill, and descriptions of certain species have been given in the *Journal of the Bengal Asiatic Society*, but further material and more detailed information are deemed essential before the final report can be given to the public, and this seems likely to assume the form of a monograph of the Indian species of the genus. All that need be attempted here, therefore, is to abbreviate the *Dictionary* article, and to abstract and incorporate from Prain and Burkill's preliminary report (and all other recent publications) such additional information as seems calculated to bring the present account abreast of existing knowledge.

Prain (*Bengal Plants*, l.c.) sketches very briefly the classification that seems likely to be followed in the future. The Bengal species are referred to two great groups according as the stems twine to the left or to the right of the observer. This brings the following together as those that twine to the left—*D. demonia*, *pentaphylla*, *tomentosa*, *bulbifera*, *deltoidea*, and *fasciculata*; those that twine to the right, *D. anguina*, *aculeata*, *nummularia*, *amiltoni* and *alata*. Within these groups the species are assorted according to the characters of the leaves, inflorescence, capsules, seeds and aerial bulbs. It may be useful to set forth in alphabetical sequence of their names the economic information of the chief Indian species and varieties:—

iii., 126-7.
Barbados
Yam.

. *alata*, *Linn.*; *Fl. Br. Ind.*, vi., 296; Prain, l.c. 1067; *Rec. Bot. Surv. Ind.*, ii., 143; iii., 288; *Circ. Roy. Bot. Gard. Ceylon*, 1905, iii., 10-4. The Wing-stalked Yam, the Barbados Yam, *kham*. This seems closely allied to the Chinese yam, *D. atatas*, *Decaisne*.

Co onest
Indian Yam.

This is the commonest of all the Indian cultivated yams. It is a large climber with quadrangular winged stems which twine to the right. The capsule is broader than long and the seeds winged all round. Leaves rather sharply angled. Inflorescence only occasionally produced and often zig-zag in structure. Tubers frequently very large, sometimes four to eight feet in length and as thick as the thigh (*Conserv. For. Repts. S. Circ. Mad.*, May 1889), at other times small and globular like an average-sized potato. One or two species of yam are frequently alluded to in Sanskrit literature, and this would appear to be perhaps the form most often mentioned. Roxburgh assigned four or five tubers to sepa-

rate specific positions, chiefly on account of their shape and colour. He, however, admitted that he would be quite prepared to accept all these races (for they appear to be little else than races) as belonging to the same species. These were *D. atropurpurea*, *globosa*, *purpurea* and *rubella* (Roxb., *Fl. Ind.*, iii., 797-801). They are classified into tubers elongate, at times club-shaped, the flesh being white throughout in *alata* proper, pink under the skin in *rubella*, purple throughout in *purpurea*; tubers short, roundish, and flesh wholly white in *globosa*; rosy purple under the skin in *globella*, and rosy purple in *atropurpurea*. J. D. Hooker places these names as denoting "imperfectly known and undeterminable species." Prain and Burkill, however, after a careful study of the live plants, have recorded Roxburgh's four forms above named under *D. alata*, Linn., and have formed varietal positions for each (Note, l.c. 1903-4, No. 846). These are as follows:—

(a) Var. *alata* proper; *D. Hamiltoni*, Hook., f. (in part). The White Yam. This is said to be a large climber, fairly abundantly cultivated in Bengal, Assam, the United Provinces, the Central Provinces, the Deccan, South India, Burma and Ceylon. It varies very greatly, however, in some of its areas. White Yam.

(b) Var. *globosa*; *D. globosa*, Roxb., Duthie and Fuller, *Field and Gard. Crops*, pt. iii., 11; *D. globosa*, D.E.P., iii., 131; the Common Yam. This also is a large climber that is fairly extensively cultivated, more especially in the Central Provinces and Madras. It is the *chupri-alu*, *fergo-nari*. Common Yam.

(c) Var. *rubella*; a large climber, extensively grown, especially in Bengal, the Central Provinces, Western India and the Deccan. It yields a long tuber, red outside, known as the *guraniya-alu*. Long Red Tuber.

(d) Var. *purpurea*; the Dark Purple Yam: the Malacca Yam, or *lab-guraniya*. A large climber fairly extensively cultivated. Dark Purple Yam.

. *ang na*, Roxb.; *Fl. Br. Ind.*, vi., 293; Prain, *Beng. Plants*, ii., 1066. A large climber met with occasionally in the forests and jungles of the lower hills in Nepal to Bhutan, also Chota Nagpur and Assam. The tuber is only eaten by the poor or in times of scarcity, and is called *kukur-alu*. D. P., iii., 127.

. *bulb era*, Linn.; *D. sativa*, Benth.; *D. pulchella* and *D. crispata*, Roxb.; Hermann, *Parad. Bat.*, 1698, t. 217; *D. sativa*, Willd. Duthie and Fuller, *Field and Garden Crops*, pt. iii., 11, t. lxxx. *D. sativa*, Linn. Hooker (Trimen, *Fl. Ceyl.*, iii., 279) calls this "the wild uneatable state of the cultivated plant." This fairly extensive climber is common in the hedges and thickets of India and Burma. It is a distinct species, the capsule being longer than broad, and the seeds winged at the base only; the leaves are bright shining green and the transverse nerves rest within channels. The tubers are round, not larger than a man's fist. The stem, like that of *D. alata*, bears numerous little tubers by which the plant may be propagated. The aerial tubers also afford characters by which the varieties may be separately recognised. The underground tubers of the wild plant are insipid and often hardly edible, unless repeatedly boiled and washed in running water between each boiling. Nevertheless, the wild forms collectively constitute a fairly important article of food in times of scarcity and famine. [Cf. Acosta, *Tract. de las Drogas*, 1578, 321.] D. P., iii., 128-9.

A Wild Yam. A Wild Yam.

(a) V. *bulbifera* proper.—The agricultural states of this variety are often designated in India as *D. sativa*, and the recently introduced forms are spoken of as the Otaheite Potato. The wild tubers are regularly eaten, though more bitter than the cultivated. An interesting official correspondence recently took place regarding the successful conveyance (by Capt. H. D. Larymore) of seed-tubers of the so-called Otaheite Potato from the Andaman Islands to West Africa. Famine Food.

(b) Var. *pulchella*; *D. pulchella*, Roxb.; *D. sativa*, Linn.; *Fl. Br. Ind.*, vi., 295 (in part); *D. bulbifera*, D.E.P. A climber fairly generally met with in cultivation. It is in India often known as the *rat-alu*. Otaheite Potato.

(c) Var. *crispata*; Roxb., *Fl. Ind.*, iii., 802. A fairly prevalent climber in India and Burma, known as *zamin-kand*. D. P., iii., 1.

. *deltoides*, Wall.; Prain and Burkill, *Journ. As. Soc. Beng.*, 1904, lxxiii., pt. ii., suppl., 1-2, 5-6. This is a common species in the N.W. Himalaya at altitudes between 3,000 and 8,000 feet—flowering time in May. It is an extensive climber, often covering trees more or less. Stewart gives a long list of vernacular names which in the *Dictionary* it was suggested belonged to all the species met with in Upper India. Even to the present day a distribution of these names has not been accomplished. The tubers are often very large, but apparently not eaten. In Kullu they are called *shingli*, and used for wadding wool. Stewart says that in Khayhan they are called *kriess* and used in D. P., iii., 1.

Detergent Tubers.

lms

washing silk. Lawrence (*Valley of Kashmir*, 75, 78) calls them *krits* (or *kritz*), and remarks that they are much used in washing wool and also in medicine. The same tubers, according to Atkinson, are in Kumaon known as *gun*. Some writers appear to regard them as poisonous.

D. da ona, Roxb.; *Fl. Br. Ind.*, vi., 289; *Rec. Bot. Surv. Ind.*, 1898, i., 274; 1903, ii., 143, 189. A large climber of the tropical forests of India and Burma. Stems twining to the left, sometimes prickly; leaves digitately 3-5 nerved; capsule longer than broad and seeds winged at the base only. This wild yam is extensively used as a famine food, chiefly in Burma and the Central Provinces and Central India. It appears never to have been cultivated. Some writers, however, say the roots are highly poisonous and cause intoxication but are rendered edible by boiling and steeping in running water, this treatment being repeated two or three times. Gammie (*l.c.* 190) says that when tigers kill cattle, the villagers insert a quantity of the flour from the pounded roots of the *vaja kand* into the body of the "kill." The poison permeates the flesh to such an extent that when the tiger returns and eats the carcase it becomes infatuated and mad, and the villagers then make short work of it. Ridley (*Malay Pl. Names*, in *Journ. Roy. As. Soc. (Straits Branch)*, 1897, 90) speaks of the tubers being used in the manufacture of dart poison. (*Yearbook of Pharmacy*, 1898, 62-3).

.E.P.,
i., 130.
Iran Potato.

ndalu,

fasciculata, Roxb.; Prain, *Beng. Plants*, 1903, ii., 1066. The kidney-shaped yam, Karen Potato. A small climber somewhat like *D. alata* but more graceful; of a vivid green colour, the stem twining to left and dotted over with small wart-like prickles. Leaves pubescent reniform or orbicular with sharp stipular thorns. Tubers fasciculate, numerous, usually white, but in Burma and the Malay Islands a form exists which has reddish-coloured tubers. This is obviously derived from the wild *D. spinosa*, which differs only in the fact that the upper rootlets are spinose. Much confusion seems to exist regarding the name *pindalu*. In some localities of South India it denotes the white round tubers of one or two races of *D. alata*. In other provinces it is restricted to the present plant. I found (during special investigations conducted in 1894) the latter usage throughout Berar, where the clustered yam is fairly plentiful and popular. It is ordinarily grown as a garden crop near the homestead, on stakes 8 feet high and 2 to 3 feet apart, around *pan*-leaf houses, or in fields, along with the *brinjal*. In some localities, as for example Nirmal and Bassein in Bombay, it is cultivated as a pure field crop. Roxburgh tells us that in his day it was grown to a considerable extent in the vicinity of Calcutta not only for food but to make starch. Being, in some respects, more like a potato than a yam it is often called the potato of this and that place—e.g. "Karen Potato."

an alu.

glabra, Roxb.; *Fl. Br. Ind.*, vi., 294; Prain, *Rec. Bot. Surv. Ind.*, 1905, iii., 288; *D. nummularia*, Lamk.; *Beng. Plants*, ii, 1067. So far as India is concerned, however, it would appear to be rarely if ever cultivated, though the tubers are regularly collected and eaten by the hill tribes, more especially in times of scarcity and famine. It occurs on the lower North-West Himalaya, in Nepal, Sikkim, the hills of Bengal to those of South India and Burma, distributed to the Malay Peninsula and China. It is very often called *ban* (wild) *alu* or *aru* (yam), *shora-alu*. [*Cf.* Wood, *Rec. Bot. Surv. Ind.*, ii., 143.]

.P.,
ii., 13

Var. *belophylla*, Voigt (sp.); *D. sagittata*, Royle; Prain, *l.c.* 1064. It seems probable that this should be retained as a distinct species. It is a large climber met with on the lower Himalaya and mountains of Bengal (Parismath). The tubers are edible but the plant is not recorded as met with under cultivation.

.P.,
ii., 131.

amiltoni, Hook. f.; *Fl. Br. Ind.*, vi., 295 (in part); Buchanan-Hamilton, *Stat. Acc. Dinaq.*, 192; *D. globosa* (in part), D.E.P. This cultivated plant is occasionally met with in Bengal, Assam and Burma.

.P.,
ii., 13

opposita, Linn.; Roxb., *Fl. Ind.*, iii., 804; *Fl. Br. Ind.*, vi., 292. A large climber with terete unarmed branches and with the leaves almost opposite. It is a native of tropical India from the Deccan to Assam, Sylhet, Chittagong, Burma, Ceylon and China. It is wild in India but appears to be cultivated in the Malaya and Java. It is one of the most important wild tubers with the people of the Deccan and Central Bengal. The root and aerial tubers are eaten as well as the young flowering spikes.

.P.,
ii., 132.
Yam.

pentaphylla, Linn.; *D. triphylla*, Roxb.; *Fl. Br. Ind.*, vi., 289; *Rec. Bot. Surv. Ind.*, ii., 143; iii., 288; Prain, *Beng. Plants*, ii., 1066; Nuren-Kelengu, Rheede, *Hort. Mal.*, vii., tt. 34, 35. The Kawan or Fiji Yam. Met with throughout tropical India on the lower hills from Kumaon to Burma, Ceylon and Malacca. It is an

extensive climber, the stem prickly below and sometimes bulbiferous. It affords large edible tubers that are eaten practically all over India, especially with the Kathodis of the Konkan, the Savaraks of Ganjam and the Lepchas of Sikkim. The flowering stems and young leaves are also eaten, especially in times of scarcity. But it is said to afford both poisonous and innocuous forms, the latter being made edible by repeated boiling and washing. It is apparently, however, never cultivated in India, except perhaps in Pondicherry. [Cf. *Circ. Roy. Bot. Gard. Ceylon*, 1905, iii., 16-7; Achart, *Quinze Cents. Pl. dans L'Ind.*, 1905, 206.]

. *spinosa*, Roxb.—This plant has been confused with *D. fasciculata* and *D. aculeata*, Linn. It is, in fact, placed by Prain (*l.c.* 1066) as a variety of *D. fasciculata*. Its most generally accepted names are *madhvālu* in Sanskrit and *maru-ālu* in Bengali, but these are also assigned to *D. aculeata*, Linn., so that it seems probable the two plants are often confused by the people of India as also by most botanists. The tubers are largely eaten in the countries where procurable.

CULTIVATION.—Of the yams above briefly indicated three species are very generally grown in India as subsidiary foods. These are *D. alata*, *D. bulbifera* and *D. fasciculata*. Under each of these species, however, there are several varieties and even a large assortment of cultivated races, so that the yams are not only varied but abundant plants. It is, in fact, only within the very driest tracts (such as some portions of Rajputana, Sind, the Western Panjāb and the Deccan) that yams are not to be found. Wild yams are also very prevalent and constitute an important article of food with the poor, more especially the inhabitants of uncultivated tracts, and in times of famine they often become of the greatest possible value. Lewin (*Wild Races S.E. Ind.*, 1870, 27) says that in the hills of that country wild yams are so plentiful that no man, able to search for food, need starve. Speaking in general terms, a line drawn from Khatmandu and Lucknow to Ahmedabad would sever India into two portions—the Southern (more especially its south-eastern tracts) might be described as the yam-producing area of India, and the Northern (more especially its north-western tracts) the non-yam-producing division. Through Bengal and Assam the yam country extends to Burma, Siam, the Malaya (Peninsula and Archipelago) to China and Japan.

In the *Dictionary* a few passages from De Candolle were quoted and the contention advanced that the historic importance of the Indian cultivated yams had been depreciated owing to no work of sufficient merit having recorded their Sanskrit and vernacular names. "Roxburgh," says De Candolle (*l.c.* 77), "enumerates several *Dioscoreæ* cultivated in India; but he found none of them wild, and neither he nor Piddington mentions Sanskrit names. This last point argues a recent cultivation or one of originally small extent, in India, arising either from indigenous species as yet undefined, or from foreign species cultivated elsewhere." . . . "The absence of distinct names in each province also argues a recent cultivation." A very extensive assortment of vernacular names for each species has been recorded, however, by Prain and Burkill, and these amplify materially the names given in the *Dictionary*. They thus abundantly substantiate the opinion of India being one of the great centres of original production (if not the chief Asiatic centre) for yams. It seems likely that both the sweet-potato and the ordinary potato, being more tractable, have not only largely supplanted the yams but usurped their classic names and history.

Asa Gray (*Scient. Papers*, i., 322) says that Columbus when he discovered Cuba and St. Domingo found the Natives cultivating two kinds

subsidiary

Habitat.

History.

American
Habitat.

of edible roots. "These were called in the language of the islanders of St. Domingo, *Ages* (*Ajes*) and *Yuca*." The last mentioned is *Manihot* and may be dismissed from further consideration, but the former (it is nearly certain) was a species of *Dioscorea*. This the Spaniards (being ignorant of the language of these islands) called *name*, *niame*, *inhame*—corruptions, it is supposed, of an African name (with which they were already familiar) for a similar edible tuber. Clusius (*Hist. Exot. Pl.*, 1605, 237-8, reprinting Garcia de Orta, 1563, *Coll.*, xviii., 3) speaks of the African slaves of Portugal eating the tubers of a *Colocasia* which they called *inhame*. Hence that name had, at an early date, reached Europe and India. Some of the companions of Columbus had doubtless seen the *inhame* tubers of Africa, and were thus ready to assign that name to the West Indian tuber when their attention was drawn to it. To this circumstance is accordingly due the constant use (by 16th and 17th century writers) of *inhame* (or, as it ultimately became, *ihame* and finally *yam*) as a generic denomination for any and every edible (starch-yielding) tuber.

African Habitat.

Sanskrit Name.

There would seem little doubt that the Indian word *álu* (in Sanskrit and Hindi and *ala* in Sinhalese) originally denoted a starch-yielding edible tuber, possibly in its earliest signification the edible species of *Dioscorea*, though in later usage it came to mean *Amorphophallus* and even *Colocasia*. A prefix was employed to denote the separate species. Hence we have in Sanskrit the *dandálu* (elongated *álu*), *madhválu* (sweet *álu*), *pindálu* (round *álu*) and *raktálu* (red-*álu*). In the Sanskrit vernaculars we have similarly *chupriálu*, *guraniya-álu*, *kanta-álu*, *kham-álu*, *maru-álu*, *pindalu*, *ratálu*, and *sasniálu*. But in the aboriginal languages there is a vast assortment of names not only perfectly distinct from each other and in no way traceable to the Sanskrit, but which have either a direct specific or in some cases even a generic signification:—*ato sang*, *bengo-nari*, *bir sang*, *gun*, *genasu*, *kalangu*, *kullu*, *kniss*, *kris*, *myauk*, *piska*, *taguna* and *tar* (or *tarar*). Most of these names (many others might be given) denote knowledge prior to the Aryan conquests of India and thus leave no room for doubt that the cultivation of yams is quite as ancient (if not more so) in India as in any other country. Indeed from the fact that names are given in the West Indies and other tropical countries, traceable to the Sanskrit, or to some Indian vernacular, there would seem no doubt that some of the best-known cultivated forms in other regions were derived originally from India. And what is more curious, not a few of these are being brought back to India to-day as special West Indian plants, oblivious of the fact that, just as with the improved rice brought from Carolina and the superior wool-sheep from Australia, they had been procured in the first instance from India.

Aboriginal Names.

Seeds.

Soil.

Cillage.

Planting.

Propagation.—The yam may be propagated either by means of aerial tubers or small underground tubers or portions of large tubers. If the former be employed, the first year's crop is poor but the second excellent. It is preferable to use sets of the underground tuber weighing about half a pound. The best soil is a deep friable sandy loam. Stiff heavy soils are unsuited, as the tubers cannot expand properly and good drainage is essential. The selected land should be dug to a considerable depth and fairly well manured. It is then lined, 3 to 4 feet apart, and the seed tubers set on the ridges at distances of 18 inches. Some cultivators prefer to start the seed tubers in a nursery and to transplant to their permanent position when a foot or so in height.

Alongside is secured a stake (usually a bamboo) perhaps 8 to 15 feet in height above ground, and it is customary to bind these together at the top in clusters of four. It is also not uncommon to grow special trees on which the climbing stems of the yams may be trained. When this is the case pits are dug alongside of the trees and filled with new soil and manure and the sets deposited within these. Occasionally (as, for example, in Bihar) the plants are allowed to trail on the ground, but the yield is believed to be then smaller. In the West Indies, however, the crop is often treated in this way, and apparently with satisfactory results. It is also affirmed that in China the trailing stems are pegged or layered into the ground, and thus caused to root, the result being that tubers are formed at the new points of growth. With certain species, having a rhizome-like underground stem and one or two large tubers, the lower edible portion is cut off and the upper rhizome planted for next year's growth. This, however, is rather the careful system pursued with wild yams than a regular method of agricultural propagation. Planting is done in April and the crop comes into season about December. This is the usual practice, but a wide range of seasons exists in direct adaptation to local conditions and the species of plant grown. Thus in Arcot it is said the yam is cultivated in January and harvested in August and September. In the Konkan yams are sometimes grown alone and the crop comes into season about October. In Upper India, according to Duthie and Fuller, the tubers of *D. bulbifera* are planted in May and June and dug up every three years. Of *D. alata*, var. *globosa*, these authors say it is planted in June and the crop gathered the following February.

Staking.

Trailing.

Wild Stock.
Seasons.

Yield.—The yield depends largely on the plant grown, the nature of climate and soil, the degree of cultivation, and the proportion of the produce treated as edible. The yield has been variously put at from 3 to 10 tons an acre, or approximately the same as the yield of potatoes. But yams are in India most frequently a supplementary crop to ginger, turmeric, *brinjal*, sweet-potato or maize. Yams are moreover more nutritious than ordinary potatoes, so that the combined produce may be accepted, from the standpoint of food supply, as highly satisfactory.

Yield.

Supplementary
Crop.

The istry.—Bhaduri (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1902-3, 25) says the acidity of yams is due to the presence of needle-shaped crystals of calcium oxalate, and the poisonous property to the presence of the alkaloidal principle *Dioscoreine* first isolated by Boorsma of Java. Hooper (*l.c.*, 1903-4, 32) gives the results obtained during the examination of some forty kinds of these tubers. The poison was found most abundant in *D. daemona*, but was often present in *D. bulbifera* and *D. pentaphylla*. "The average amount of moisture in fresh tubers was 80 per cent., and the average percentage composition of the dried tubers was: fat 1.02, albuminoids 10.87, carbohydrates 77.01, fibre 5.16, ash 5.94, and nitrogen 1.73. The starch of the yams was examined microscopically and certain species were found to have characteristically shaped granules, which distinguished them from other species."

[*Cf.* De Candolle, *Orig. Cult. Plants*, 1884, 76-81; Asa Gray, *Scient. Papers*, 1889, i., 322-6; Mollison, *Handbook Ind. Agri.*, 1901, iii., 197-200; Mukerji, *Handbook Ind. DIO PYRO, Linn.; *Fl. Br. Ind.*, iii., 553-72; Gamble, *Man. Ind. Timbs.*, 453-63; Cooke, *Fl. Pres. Bomb.*, i., 98-107; Prain, *Beng. Plants*, i., 651-4; Brandis, *Ind. Trees*, 428-36; **EBENACEÆ**. A fairly important genus which embraces about 59 species of Indian forest trees. They occur chiefly in South India, Ceylon, Burma and Eastern Bengal. Only four extend to Northern India, while the genus may be said to be not represented in the Eastern Himalaya. All the species yield useful timbers, of which the best are the various forms of Ebony (*D. Ebenum* and *D. melanoxylon*), known in the vernaculars of India as *ebans* or *tendu*. The most important are:—

bony. **D. benu**, Koenig.; Roxb., *Fl. Ind.*, ii., 529; Trimen, *Fl. Ceyl.*, iii., 94. The **EBONY**, *ebans*, *abnús*, *tendu*, *khenda*, *temrú*, *tai*, *acha*, *nulliti*, *shengútan*, *kakati*, *tuki*, *kare*, *bale*, *mushtimbi*, *karunkáli*, *mallali*, *kaluware*, etc., etc. A large tree not very common in India, where it is found in the Deccan and Karnátak, chiefly in dry evergreen forests in the Ceded Districts. In Ceylon, however, it is one of the chief woods, very common in the dry regions of the Northern Provinces. [Cf. Herbert Wright, *The Genus Diospyros in Ceylon, its Morphology, Anatomy and Taxonomy*, 1904.]

mber. This species is perhaps the best ebony-yielding tree and the only one which gives a black heart-wood without streaks or markings. Gamble says 74 lb. is the average weight per cubic foot for the heart-wood. In Europe it is extensively used for ornamental turnery, cabinet-work, piano keys, rulers, etc., and in China for chopsticks, pipes, carved stands and vases. **ade.** Ebony does not appear to be exported from India to any material extent, but in Ceylon the average sales for 1892-1902 were 300 tons yearly. The average price Gamble gives at 180 to 185 Rs. per ton. *The Indian Forester* (1905, xxxi., 37, app.) gives £6 to £10 per ton as the price of East Indian Ebony.

ab. **bryopteris**, Pers.; Roxb., *Fl. Ind.*, ii., 533; *Rec. Bot. Surv. Ind.*, ii., 30, 115, 240, etc.; iii., 233; Talbot, *List Trees*, etc., 211; Trimen, *l.c.* 93. The *gáb*, *makur-kendi*, *kúsi*, *timbori*, *tumbika*, *pani-chika*, *karunthali*, *kavi-kattai*, *hollet-upra*, *tumúl*, *tinduki*, *nitta-tumma*, *kusharta*, *hige*, *bantha*, *vananchik*, etc., etc. A dense evergreen tree found throughout the greater part of India in shady wet places and near streams. It is frequently cultivated both for ornament and for its large red, velvety fruits.

am. Many writers speak in general terms of a gum obtained from this plant, but do so in such a manner as to suggest a confusion between a true gum and an extract prepared from the fruit, the pulp of which is used in book-binding, and in place of tar for paying the seams of boats. According to some writers the pulp is used direct; others say an extract or decoction is prepared. Buchanan-Hamilton (*Stat. Acc. Dinaj.*, 1833, 152) thus describes the process pursued in Bengal:—"It (the fruit) is beaten in a large mortar and the juice expressed. This is boiled, mixed with powdered charcoal and applied once a year to the outside of the planks." Duncan (*Monog. Dyes and Dyeing in Assam*, 1896) observes that the half-ripe fruits are pounded in a mortar and then kept six or seven days in water until they have decomposed. A gummy solution results, which is poured off and the sediment thrown away. The brownish liquid thus obtained is used in dyeing and tanning. It is made into a good black by being combined with myrobalans (*Terminalia Chebula*) and proto-sulphate of iron (*hira-kash*). The infusion is largely employed for tanning fishing nets and lines, and it makes them more durable.

er- **akí**, Linn.—A small tree met with in the Khasia hills and perhaps also in Upper Burma. It is cultivated here and there over the moister tracts of India as a fruit tree, but is only suited to very large gardens. It is the **CHINESE DATE PLUM** or **PERSIMMON**, and in Burma appears to be known as *tay*, *teh*. The fruit ripens during August and is about the size of a large apple with twin almond-like stones. The rind is of a rich, ruddy colour. It has a rather disagreeable odour, and in flavour is suggestive of an overripe apple. A fine preserve is said to be made from it by the Chinese. [Cf. Roxb., *Fl. Ind.*, ii., 528; Firminger, *Man. Gard. Ind.* (ed. Cameron), 1904, 221-2.]

reserve. **arble-** **voood.** **Kurzii**, Hiern.—One of the most important trees of the Andamans, termed in English **MARBLEWOOD**; in Burma *teakah*, *thitkya*, and in the Andamans *pecha-da*. Gamble remarks that this wood would be of great value in the

European market, were it procurable in sufficient quantity. *The Administration Report, Andaman Islands* (1898-9) speaks of squares up to 12 feet (siding up to 6 inches) being obtainable.

D. Lotus, *Linn.*—A medium-sized tree, met with in the Panjáb Himalaya, Hazara, Kashmir, Baluchistan and Afghanistan. It is the *amlúk*, *malúk*, etc. It yields a gum said to cause a large quantity of water to solidify to a jelly (*Ann. Rept. Ind. Mus. Calc.*, 1901-2, 24). The ripe fruit is largely eaten either fresh or dried. It is imported by the Kabulis into Peshawar and is often used in the preparation of sherbet.

Amlúk.

Gum.
Fruit.

elanoxylon, *Roxb.*—A medium-sized tree found, according to Gamble, in South India, in the dry forests of the Maratha country, the Deccan and Karnatak; but Brandis, by regarding it as doubtfully distinct from *D. tomentosa*, extends its area to the deciduous forests of the Central Provinces, Chota Nagpur, Bihar and the Western Peninsula. It is known in trade as COROMANDEL EBONY and by the following, amongst many other names:—*tendu*, *kendu*, *temru*, *abnus*, *tumi*, *kari-mara*, *damádi*, *balai*, etc. Speaking of *D. melanoxylon* proper, Gamble observes large trees are uncommon and the amount of ebony small; of *D. tomentosa* he says that it is the tree which gives the ebony most largely used in North India. From it is made the Nagina (Bijnor district) black carved woodware. For full particulars of that art centre and its utilisation of ebony, consult *Indian Art at Delhi*, 1903 (100, 112-3, 123, 149, etc.). The fruit ripens about December and is edible. During famine it is pounded and made into bread. [*Cf. Banerjei, Agri. Cuttack*, 1893, 185-6, 195; *Cameron, For. Trees Mysore and Coorg*, 1894, 178; *Hove, Tours in Gujarat*, etc., 1787, 145.]

Coroman-
del Ebony.

Nagina
Wood-carving.

ontana, *Roxb.*—A small tree found throughout India and Burma. It is known as a form of *tendu*, but its distinctive names, among others, are:—*ban-gáb*, *tembhurni*, *gara-tiril*, *lohari*, *hirek*, *goindu*, *makartendi*, *jalagaganti*, *ambia*, *hádru*, *kachan*, *muchi tanki*, *taubut*, etc. It does not grow to a large size, and the timber, though described as a beautiful furniture wood, is rarely suitable for such purposes. According to Day (*Fishes of India*) the fruits of the *bistendu* or *kuhar* are thrown into the water to kill fish. Kanjilal (*For. Fl. of School Circ. U. Prov.*, 1901, 220-2) says every part of the tree, including the fruit, is bitter and has an unpleasant smell.

IPT R CA PU, *Gaertn., f.; Fl. Br. Ind.*, i., 295-9; Gamble, *Man. Ind. Timbs.*, 1901, 70-3; *Prain, Beng. Plants*, i., 251-3; Brandis, *Ind. Trees*, 65-6; DIPTEROCARPEÆ. A genus of lofty trees, which embraces some 50 species, natives of tropical East Asia. Of these 17 occur in the Indian area and some 8 or 9 in India proper. On purely economic grounds I propose to treat as species plants that may be only doubtfully distinct botanically, but in doing so I am practically following the lead given by Prain. The various forms are chiefly noted for their oleo-resins and timbers. The unimportant species are:—

D.E.P.
iii., pt. i.,
157-71.

. alatus, *Roxb., Fl. Ind.*, ii., 614. A very large tree, native of the tropical forests of Burma, where it is known as white *kanyin* or *kanyinbyn*. It gives a large quantity of a rather thin wood-oil. Gamble remarks that this is probably considerably mixed with that of *eng*. [*Cf. Roxb., Trans. Soc. Arts*, 1806, xxiii., 413.]

D. .P.,

Malabar
Wood-oil.

. indieus, *Bedd.*; Brandis, *Journ. Linn. Soc.*, xxxi., 26; *D. turbinatus, Fl. Br. Ind.*, i., 295 (in part); Talbot, *List Trees*, etc., 1902, 33; Cooke, *Fl. Pres. Bomb.*, 1901, i., 84. The *guga*, *challane*, *ennei*, *kalpayin*, *varangu*, etc. A lofty tree of the evergreen forests of the Konkan, Kanara, Malabar and Travancore. The wood-oil tree of Western and Southern India.

The Conservator of Forests, Coorg, gives an account of the wood-oil prepared in that portion of the west coast of Southern India. He says—"We have two oil trees in the Western Ghat Forests of Coorg. Both, I believe, are species of *Dipterocarpus*, but have not been able to get the flowers to identify them. The oil is contained in the pores of the wood, and is collected by cutting a hole into the centre of the tree. One species yields a yellow oil and the other a dark red.

Two Oils.

The former is sold in the bazars mixed with dammar (the produce of *Vateria indica*) as varnish at 5 annas a bottle. The latter also makes a fair varnish. It has a strong copaiba-like smell and would probably be useful in medicine." One at least of these oils must be regarded as afforded by the present species, whether it be accepted as distinct from *D. turbinatus* or only a variety of it.

D.E.P.,
ii., 15 -9.
Telia-
garjan.

D. laevis, Ham., Mem. Wern. Soc., 1832, vi., 298-9; *D. turbinatus*, Roxb., Fl. Ind., ii., 612 (in part); Fl. Br. Ind., i., 295 (in part). Prain speaks of this as a tall tree met with in Tippera, where it is known as *telia-garjan*. He remarks that as so accurate an observer as Buchanan-Hamilton separated his *laevis* from *turbinatus*, on account of their different economic properties, it seems better to leave the two trees as distinct species. In a letter to Roxburgh dated Oct. 16, 1798, Buchanan-Hamilton speaks of four species of "*gurjeon*" found by him in Chittagong, which doubtless included the present species.

D. obtusifolius, Teysm.—A large deciduous tree of the *eng* forests of Prome and Martaban. It is the *kanyingok*, *inbo*, *in-kohe*.

D.E.P.,
ii., 159.
Hollong.

D. pilosus, Roxb., Fl. Ind., i., 615. A tall evergreen tree of Assam, Chittagong and Burma. It is best known as the *hollong*. Brandis observes that it yields a semi-fluid resin, and it is described by Hooper as white (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1904-5, 24). Gamble speaks of the wood as good but not suited for tea-boxes. Peal refers to it as employed for canoes. This is possibly the tree mentioned by Robinson (*Desc. Acc. Assam*, 1841, 62).

D. P.,
iii., 160-1.
ng.

. t bereul tus, Roxb., Fl. Ind., ii., 614. The Eng Tree, *eng*, *in*, *sooahn*. A large deciduous, gregarious tree forming the "*in (eng)* forests" of Burma, Chittagong and Siam. It is said to be very characteristic of laterite soils and to take the place of the *sal* in Northern and Central India.

Wood-oil.

Oleo-resin.—It was for some time thought that the *eng* tree did not give a wood-oil, but Mr. J. W. Oliver explained that it yielded a thick oil or rather oleo-resin. The reader will find Mr. Oliver's most interesting report in the *Dictionary* (iii., 160-1). The method of extraction is very similar to that for *garjan*-oil, explained below. The congealed resin which remains behind, after the removal of the oil, is scraped off and used for torches which are made of rotten wood, mixed with the resin and rolled up in the leaves of the *satthwa*, a species of screw-pine. In some localities, however, the rotten wood is soaked in the oil itself and wrapped up in the leaves of a palm-*salu* (*Licuala peltata*). Nisbet (*Burma Under Brit. Rule and Before*, 1901, 365) says that "twenty years ago the chief luminant used after dark through the rural tracts, except those of the dry zone within easy reach of the central petroleum fields, was a small torch about a foot and a half long made of chips of dead wood and the resinous oil of the kanyin or wood-oil tree *D. turbinatus* rolled in palm leaves. . . ." "These kanyinsi torches were sold in bundles in every bazar. While burning they emitted incessant smoke and a strong oily smell, pungent and differing vastly from the European idea of fragrance. At one time the manufacture of these torches formed an industry wherever the wood-oil trees abounded; but now, in consequence of improved communications and of large imports of kerosene at low rates, torch-making is only betaken to in jungle tracts in order to eke out the means of livelihood during bad years, when the shadow of misfortune darkens the threshold."

Torch es.

Oil.

Timber.

The oil is used for waterproofing bamboo baskets, etc. With regard to the wood, Gamble (*l.c.* 72) says, "The *Eng* is probably the best of the woods given by the species of *Dipterocarpus*, and it is in considerable demand and use for building and boats." In point of weight it would seem to average 54 lb. [*Cf.* Brandis, *Ind. For.*, 1875, i., 365; Semler, *Trop. Agrick.*, 1900, ii., 536-7.] Hooper (*Agri. Ledg.*, 1902, No. 1, 15) mentions a tannin extract obtained from the bark of this tree.

D. t rbi t s, Gaertn., *f.*; Buch.-Ham., *Mem. Wern. Soc.*, 1832, *D. P.*, vi., 300; Roxb., *Fl. Ind.*, ii., 612 (in part); Ribbentrop, *Forestry in Br. Ind.*, 1900, 10. Kanyin Oil Tree, *garjan*, *dulia garjan*, *kanyoung*, *kanyin*, *kanyin-né*, *kanyin kohe*, etc. An evergreen tree of Eastern Bengal, Chittagong, Burma, and (according to Gamble) of the Andaman Islands. Distributed to Singapore. *iii.*, 161-71. **Kanyin.**

One of the loftiest of Indian trees, being sometimes 250 feet in height. Hooker (*Himal. Journ.*, ii., 348) in his account of Chittagong says: "This is the most superb tree we met with in the Indian forests: we saw several species, but this is the only common one here; it is conspicuous for its gigantic size, and for the straightness and graceful form of its tall unbranched pale grey trunk and small symmetrical crown: many individuals were upwards of 200 feet high and 15 in girth." In recent official correspondence mention has been made of a broad and narrow-leaved *garjan* oil plant. The latter has been determined to be a special variety of *D. turbinatus*, for which the name *andamanicus* has been suggested, and the former is *D. Griffithii* (see above). Lofty Trees.

OLEO-RESIN.—With regard to the various species of *Dipterocarpus* that yield wood-oil (*garjan*), the following information was obtained some few years ago from the Government of Burma:—"Kanyin oil is the produce of *D. laevis* (*kanyin-in* = red *kanyin*) and of *D. alatus* (*kanyin-byu* = white *kanyin*), which are common in evergreen forests, and probably of other species of similar habitat." It seems likely, however, that the source of the superior quality of oil has changed within recent years owing to the comparative extermination of the plant most noted in former times. It is also highly probable that the plant valued at the present day may be a species but indifferently known to botanists. Every here and there, more than one grade of oil is described by popular writers, whereas in most cases only one species of wood-oil tree is recognised. It is on that account that I have retained for the present the names used in the *Dictionary*, namely, *D. laevis*, *D. tuberculatus* and *D. turbinatus*. Oil.

Garjan Oil is in Burma generally collected in the dry weather only—(November to May). In the Andaman Islands it does not flow before January 15, and is finished by April 25. The oil is obtained by cutting two or three deep pyramidal hollows (the apex pointing towards the interior) near the foot of the tree, and by applying fire to the upper cut surfaces. The fluid then collects at the bottom of the hollow, which is emptied every three or four days. Fire is applied after the oil is removed, and the upper surfaces of the hollow are chipped three or four times during the season. In Tharawaddy district, where trees are not very plentiful, it is considered that twenty are about as many as one man can attend to. The yield of twenty trees would be 100 *viss* for the season, worth Rs. 25. In Prome district the oil may be said to come into the market in the form of torches similar to those already discussed under *D. tuberculatus*. In the *Forest Administration Reports of the Andaman Islands* (1897-8, 7; 1899-1900, 4, 5; 1901-2, 13; 1903-4, 7) particulars are given of the methods pursued in collecting the oil. In the Chittagong district it is prohibited to tap the trees owing to the large number already killed. This prohibition it is understood does not extend to the hill tracts. A recent official communication, for example, states Various Grades.

Copaiba.

Chinese
Wood-oil.

Very little is known for certain of the industrial uses of the oil, still less of the resinous concretion as distinct from the liquid oil. The former is fairly extensively employed by the Burmese for torches, and the oil is largely used in preserving bamboo wickerwork and in paying the seams of boats. As a varnish it is believed to protect woodwork from the ravages of insects. In Europe it has been in fact made into a varnish, and is reported to be a useful ingredient in lithographic ink. It was in the *Dictionary* pointed out that an important way of utilising the article might be found in taking advantage of Mr. Laidlay's discovery that it acts as a solvent to caoutchouc. Sir W. O'Shaughnessy remarked fifty years ago that it would likely be found a perfect substitute for the expensive balsam of copaiba. In the *Journal Chemical Society* (1902, xxi., 1404) it is affirmed that "Chinese wood oil" is not suitable to replace linseed oil in the preparation of varnishes. It cannot be heated above 160° C. *Capital* (April 1904) gives useful particulars regarding Chinese wood-oil—a substance which cannot possibly be mistaken for *garjan* (see p. 46).

Specific
Variability.

Adulteration.

Chemistry.—In the *Dictionary* will be found an abstract of the results obtained by the distinguished authors in the *Pharmacographia*. More recently Hooper has published his examination of the samples procured by the Reporter on Economic Products, from which the following passage may be furnished:—"Eighteen samples of *garjan* balsam from Bombay, Madras, Tippera, Chittagong, Assam and Burma had been submitted to analysis. The specific gravity ranged from 0.957 to 0.999, the percentage of volatile oil from 36.9 to 71.1, and the acid number from 3.12 in a Chittagong sample to 21.9 in one from Rangoon. These oils, procured from *D. turbinatus*, *D. laevis*, etc., were very irregular in composition and physical contents, and would lead one to believe that adulteration is practised in certain quarters. The balsam secreted by *D. tuberculatus* and known in the trade as 'Jusi' is more uniform in composition. It has a thick honey-like consistence with a high sp. gr. and acid value, but a low proportion of volatile oil. Samples of the oleo-resin of *G. Griffithii* and *D. turbinatus*, var. *andamanicus*, collected from botanically authentic sources from the Andamans, were of exceptionally good quality. The chemical examination of a series of balsams of this character enables one to recognise their peculiar reactions, so that it is easy to detect substitutions and adulterations. During the course of the inquiry a sample of oleo-resin from South India, although labelled *Dipterocarpus*, was found to be the product of the '*yen nemaram*' (*ardwickia pinnata*). . . . To thoroughly understand the differences of composition of gums, resins, and oleo-resins, samples should be collected from the trees and the conditions of age, climate, soil, etc., studied on the spot." [Cf. Wiesner, *Die Rohst. des Pflanzenr.*, 1900, i., 236-7; Tschirch and Weil, *Acc. Gurjun Balsam*, in *Proc. American Pharmacut. Assoc.*, 1904, lii., 700-1; *Pharm. Journ.*, 1905, lxxiv., 722; Tschirch, *Die Harze und die Harzhälter*, 1906, i., 489-512; Hooper, *Rept. Labor. Ind. Mus.* (Indust. Sec.), 1906-7, 8; *Pharm. Journ.*, 1907, lxxviii., 4.]

medicine.

Medicine.—This substance is not very largely used in Indian medicine, and does not appear to have been known to the early authors. It is apparently alluded to in the *Makhzan*, but it is not mentioned by Dutt in his *Materia Medica of the Hindus*. The most recent opinions on the subject only need be here quoted. Dr. Dougall and subsequently Moodeen Sherif (*Mat. Med. Mad.*, 1891, 49-50) drew attention to the properties of the oil. The latter says, "The best medical properties of this oil are its usefulness in gonorrhoea and gleet, and in all forms of psoriasis, including lepra vulgaris." Again: "With regard to its usefulness in psoriasis and lepra vulgaris, I am not aware of any other local stimulant which is more efficacious in those diseases than this drug." But in the *Pharmacographia Indica* (i., 192) mention is made of the investigations conducted by the Government of India, and it is then added that "as far as we have heard the new treatment has not been a success." [Cf. Dymock, *Mat.*

TRADE IN GARJAN OIL

IFLO U
Horse-gram

Med. W. Ind., 1885, 88-9; Waring, *Baz. Med. Ind.*, 1897, 70-2; Ponder and Hooper, *Mat. Med. Ind.*, 1901, 32.]

Gamble (*l.c.* 71) remarks that the WOOD of the *garjan* tree is used in house-building and for dug-out canoes, as also for packing-cases, but that it is soon destroyed by white ants. Its large size, however, makes it valuable for temporary purposes; logs 40 to 60 feet in length are sometimes procurable. With regard to weight he tells us that the specimens he had examined averaged 50 lb. per cubic foot. [*Cf. For. Admin. Rept. Burma*, 1899-1900, 18; *Working Plans Rept. Pyinmana*, 1904, 16-7.]

Timber

Trade.—Milburn (*Or. Comm.*, 1813, ii., 315) mentions wood-oil, and explains the uses it is put to. Royle, writing in 1840 (*Prod. Res. Ind.*, 77), speaks of wood-oil, but says it has never become an article of commerce. Flückiger and Hanbury (*Pharmacog.*) state that the world's supply is obtained from "Singapore, Moulmein, Akyab, and the Malayan Peninsula and that it is a common article of trade in Siam." Dymock (*l.c.* 91) remarks—"Garjan Balsam is not an article of commerce in Bombay; small quantities may be sometimes obtained in the Native drug shops. The Government supplies have been obtained from the Andaman Islands." Moodeen Sheriff (*l.c.* 49) writes that in Madras wood-oil is common in most large bazárs; he describes several forms and gives their prices. A firm of Calcutta merchants, in a letter dated October 25, 1900, undertook to supply *garjan* oil in 40-gallon casks at Rs. 47 per cwt. delivered in Calcutta. An official correspondence in 1901 resulted in the discovery that some objection existed in the minds of European merchants in Rangoon to engage in the traffic in *kanyin* (*gargan*) oil. One firm reported that the quality of the oil varies very much, and the price accordingly. The quotation given by them at that time was Rs. 60 per 100 *viss*—equal to about Rs. 20 or £1 6s. 8d. per cwt., but this does not include casks or drums. The Conservator of Forests in a communication of same date was of opinion that if an assured demand arose, there would be little difficulty in procuring local persons willing to supply the oil in Pyinmana Division, the Ruby Mines Division and Tenasserim Circle. It will thus be seen that very little of a satisfactory nature can be furnished regarding the Indian supply of this article. There are four chief centres of production—Burma, Andaman Islands, West and South India and Chittagong. The last mentioned, though formerly perhaps the most important, is the least valuable at the present day, and therefore it may be said that the supply, such as it is, comes almost exclusively from Burma and the Andaman Islands and is exported from the port town of Rangoon chiefly. The returns in one province appear as lb., in another as *viss*, in a third as gallons, so that a combined statement is impossible. Moreover, in official statistics it is sometimes grouped with "resin," at others with minor forest produce. One point only seems indicated, namely that with the growth of the Chinese wood-oil (*Aleurites Fordii*, p. 46) a decline in both the supply and demand of *garjan* has taken place.

Commercial Importance.

Objections to Trade.

Demand Insufficient.

iii., 175-
Horse-
gram.

i., 391; Duthie, *Fl. Upper Gang. Plain*, i., 229; Cooke, *Fl. Pres. Bomb.*, i., 382. Horse-gram, *kúlthí*, *kurthi-kalai* or *kurthi* or *kurti*, *kalath*, *khulti*, *kolatha*, *kulat*, *gahat*, *horec*, *barát*, *roiong*, *gágli*, *botang*, *wulanalli*, *ulava*, *hurahi*, *hulga*, *hulle*, *papadi*, *múthera*, *simbi*, *beji máh*, *khárek*, *pé-ngapi*, etc.; *guár*, sometimes given to this plant, more correctly denotes *Cyamopsis psoralioides*.

Varieties and Races.—According to Baker (*Fl. Br. Ind.*, l.c.) there are two forms of this plant, *D. uniflorus*, a sub-erect annual, and *D. biflorus*, a more or less twining plant. The habitats of these forms are not separately recorded. He apparently treats of both when he says it occurs on the "Himalayas to Ceylon, and Burma, ascending to 3,000 feet in Sikkim, sometimes cultivated. Distributed everywhere in the tropics of the Old World." The writer, however, is of opinion that a mistake may have been made in linking the Himalayan with the plains plant. Roxburgh refers to two forms, one with grey, the other with black seeds, both of which he implies are cultivated in Bengal and Madras. The grey-seeded plant, *D. biflorus*, is erect, has twining branches, and is about 2 to 3 feet high. Roxburgh then adds—"I have never found it but in a cultivated state." As already observed, there would appear to be room for doubt as to whether the grey and the black-seeded forms of Roxburgh are the two forms of modern writers, or whether both of Roxburgh's plants constitute but cultivated races of one of these forms. In popular works on economic products the horse-gram of Madras is viewed as *D. uniflorus*, and under either of these names (*D. uniflorus* or *D. biflorus*) a pulse is described as grown in almost every district of India, but chiefly in Madras and Bombay. It is a little difficult to believe that the plant of the tropical plains is the same as that of the temperate Himalaya, but of course this is by no means impossible. Duthie, however, says that as grown on the Himalaya it is more robust, the pods larger and broader, and the seeds grey. Mollison (*Handbook Ind. Agri.*, 1901, iii., 82-4) speaks of two varieties: one, grown sparingly in the Ahmednagar and Kaira districts, has creamy white seeds; the other, commonly cultivated, has grey variegated seeds. But that this cultivated pulse should be regarded as a native of India is abundantly confirmed by the existence of a Sanskrit name—*kulattha*—from which no doubt many of the above vernaculars (*kúlthí*, etc) have been derived.

CULTIVATION.—Of the plains it may be said that this pulse is grown either as a green manure or as a cattle food and fodder. Mr. Robertson (*Saidapet Farm Repts.*) deals with the advantages of using it as a green manure. Since then, however, the subject of the influence of leguminous crops on the soil has undergone a complete revolution. Their chief value, it is now believed, lies in their power to fix the nitrogen in the soil through the agency of the organisms contained in their root warts. Few Indian crops are perhaps more valuable in this respect than the horse-gram, especially when grown as a fodder plant, or still more so as a green manure. The advantages of growing the crop as a source of fodder are extolled by various writers. Robertson, for example, says that it produces from 2,000 to 4,000 pounds of fodder in two months, at a cost of about Rs. 3 per ton, and thrives with a minimum rainfall in very hot weather. The ease with which it may be cultivated recommends it most highly as a catch crop for forage purposes, either to be grazed on the land or fed in the stalls. The plant may be made to grow at almost any season of the year. It requires but one shower of rain to start its growth, but even if this be not obtained, the seeds have the power of remaining alive for months in the soil and of germinating when rain does fall. After the removal of the *rabi* crop it is contended that a highly advantageous course is to rapidly dress the soil, sow horse-gram, and in a month's time commence to use the stems and leaves as fodder. By this means the soil is saved from becoming baked with the advancing heat of summer, and the roots left in the soil greatly improve it, even should the cultivator be unable

PROVINCIAL PRODUCTION

to devote the entire crop as a green manure. The following brief account, province by province, may be found instructive :—

Bengal and Assa .—Horse-gram is very little cultivated in the Lower Provinces. It is said to be grown to a limited extent in Shahabad, and fairly abundantly in Chota Nagpur, both as a grain and a fodder crop, but not in Lower Bengal. Mukerji (*Handbook Ind. Agri.*, 1901, 263) observes that the time for sowing *kulthi* for grain is October or November, and for fodder June, August and November, three times on the same field. It may be reaped during several months, according to the purpose for which required, but the general harvest is December-January. The quantity harvested per acre Mukerji gives as 300 lb. of grain, or 5 tons of green fodder per crop. Banerji (*Agri. Cuttack*, 1893, 80-1) discusses its merits as a *rabi*, while Basu (*Agri. Lohardaga*, 1890, 34) calls it a *kharif* crop. Speaking of Assam in a subsequent report (*Agri. Ledg.*, 1903, No. 5, 135), he says that *kulthi-máh* is grown to a small extent in Kamrup and Darrang. In the Tezpur Sub-division it is cultivated by Nepalese and coolie settlers, and in Upper Assam and Nowgong is unknown. Only one variety is grown. The method of cultivation and time of sowing and reaping are very much as with *máti-máh*. About 5 seers of seed are sown per acre; thin seeding is desirable, the object being to allow the plants to creep and spread over the ground. A good crop may yield up to 6 maunds of pulse per acre.

Seed.
Yield.

Upper India.—Duthie and Fuller (*Field and Garden Crops*, pt. iii., 2, t. lxxx.) say that in the United Provinces *D. biflorus* is grown mostly as a rainy-season hill crop, ascending the hills to 7,000 feet. Atkinson (*Himál. Dist.*, 343, 460, 696) and Stewart (*Pb. Plants*, 1869, 68) make very similar statements. According to Sir J. B. Fuller, *Dolichos biflorus* is grown in the southern districts of the Central Provinces as a cold-weather crop, but is of importance only in the Chanda, Bhandara and Balaghat districts.

Upper India.

Seasons.

Bo bay.—Mollison (*Textbook Ind. Agri.*, 1901, iii., 83) observes that *kulthi* takes the third place among the pulses of the Presidency, and according to statistical returns occupies over 500,000 acres annually. The *Agricultural Statistics* give an average for the five years of over 2,700,000 acres under "other food grains including pulses." Briefly stated, it may be observed that Gujarat and the Konkan are unimportant sources of supply, but that the Deccan and the Karnátak are fairly important (especially the districts of Ahmednagar, Satara, Poona, Dharwar, Belgaum and Bijapur). The principal cultivation is in the *kharif* season as a row or mixed crop, subordinate to *bájri*, hemp (*ambadi*) and niger seed; only rarely is it a pure crop. Occasionally, however, it is grown in the *rabi* season as a second crop in rice fields. It is very sparingly cultivated in Bombay as a green manure. Of the Deccan, Mollison says *kulthi* participates in the general cultivation given for *bájri* (*Pennisetum typhoideum*). The fields in which it is grown are rarely manured oftener than once in three years. The land is usually prepared by working a heavy-bladed harrow (*rakhar*) two or three times in the hot weather, and again two or three times after rain in June. As a mixed crop it is sown in July, and may occupy every fourth row. The crop is generally bullock-hoed twice a year. If sown in July, the crop will be ripe at the end of October or early in November.

Mixed Crop.

Madras.—The crop is very important in this Presidency. Nicholson

adras.

Sowing.	(Man. Coimbatore) tells us that it grows on the poorest soils, and with the minimum of rainfall. Horse-gram land is seldom manured, otherwise than by casual droppings of cattle: it is usually ploughed, sown, and the seed covered by a second ploughing; or the seed is simply scattered broadcast over the natural surface and then ploughed in. As it requires only one good rain after appearing above ground, it frequently gives a fair crop when nothing else can live. When the south-west monsoon
Catch Crop. Seasons.	rains are too late for <i>kámbu</i> (<i>bájra</i>) it is frequently sown as a substitute in September, but it is also sown largely in November after the first burst of the north-east monsoons. It is pulled up by the roots, thrown into heaps, and then trodden out by cattle. The yield is up to 1,200 lb.
Area.	Nicholson (<i>l.c.</i> , 1898, ii., 176) gives 194,777 acres as the average under <i>D. biflorus</i> for the years 1888-93. Mr. H. Goodrich, Collector of
Soil.	Bellary, says a mixed soil is best suited for the crop. The fields should be ploughed and harrowed once or twice, but not irrigated nor (generally) manured. Several other Madras writers, however, give very different accounts of the requirements of this plant, so that the practice seems to vary considerably within the Presidency. In the <i>Survey Settlement Report of South Arcot</i> , for example, it is said: "The land is ploughed four or five different times after the month of May, and the gram sown between the latter part of August and the end of September. It is gathered in the middle of March." So again, Moore (<i>Man. Trichinopoly</i> , 72) speaks of it as a precarious crop. In the North Arcot District, Cox (<i>Man. North Arcot</i> , 1894, ii., 184) gives 48,897 acres as the average under <i>D. biflorus</i> for the years 1887-93. Unfortunately, while several writers mention figures of area for the districts with which they are familiar, no definite statement of the Presidency as a whole can be furnished, for the reason that horse-gram does not appear to be separately returned. The official figures under "gram" for Madras come to an average (for the five years 1900-5) of almost 150,000 acres. But under "other food grains including pulses" 7,092,389 acres are shown as the area in 1902-3, though it has since contracted to 5,753,913 in 1904-5. It is thus fairly certain that "horse-gram" must be included under the latter, and that the former denotes Bengal gram (the true gram) grown in the Madras Presidency. As indicative of the possible regions of greatest cultivation of this pulse, it may be here added that Bellary had in 1902-3 (when the largest area for the period 1900-5 was returned), 822,685; Anantapur, 771,267; Karnul, 708,877; Kistna, 554,757; and Salem, 590,619 acres devoted to the combined food crops mentioned above.
Area.	
Mysore.	<i>Mysore</i> .—Rice (<i>Mysore Gaz.</i> , 1897, i., 119-20) says the horse-gram is of two kinds, black and white, sown intermixed. In the east the worst qualities of soil are generally used, and on the same fields <i>sáme</i> (<i>Panicum Crus-galli</i> , var. <i>frumentaceum</i>), <i>hárika</i> (? <i>Curcuma longa</i>), and <i>huchchellu</i> (<i>Guizotia abyssynica</i>) are cultivated, without one crop injuring the other, or a rotation being even considered beneficial. For horse-gram plough twice, in the course of a few days, any time in October-November. Then, after a shower, sow broadcast; or, if rain does not fall, steep the seed for three hours in water and plough into the soil. It requires no manure, and in three months is ripe for harvest.
Fixed Crop.	FOOD AND FODDER .—The interest in this pulse is mainly as an article of cattle food, the green stems and leaves being a valued fodder,
Terminated seed.	
Food.	

AREA AND YIELD

Horse-gram

when grown for that purpose. Although not deemed a superior pulse it is largely used by the poorer classes, being perhaps the cheapest of pulses. The pea is generally soaked for twelve hours, then husked, thus reducing it to the form of *dál* or split-peas. The husk obtained is regarded as a valuable cattle food. The split peas may be reduced to meal, or boiled, or fried and eaten with rice or other articles of diet. The flour is fairly extensively employed in the preparation of sweetmeats. In some parts of the country the grain is dry roasted (parched), then sold to the consumers, who boil it in the preparation of *dál*.

Cheapest Pulse.

Flour.

Parched Grain.

Cattle
Food.

The pea is boiled entire and given when cold as an article of cattle food. It is one of the chief pulses so used in Madras and Bombay. Some years ago Robertson performed a series of experiments to test the merits of boiled as compared with steeped horse-gram both on draught cattle and horses. The verdict was in favour of the steeped grain. [*Cf. Rept. Agri. Dept. and Exp. Farms Mad.*, 1871, 4-7.] It is most important that in any attempts that may be made to extend this use to other parts of the world, the distinction should be clearly observed between the horse-gram of Madras (the article here dealt with) and the far superior pea known as Bengal gram (*Cicer arietinu*, pp. 295-302)—the true gram of India. It is also extremely important that both these and all the other peas and beans of India should be recognised as distinct from the *khesári* (*Lathyrus sativus*, p. 703)—a pulse with an evil reputation that has on more than one occasion injured the prospects of a foreign demand for Indian pulses.

Evil Reputation.

The fodder is either a by-product of the cultivation of the pea (*bhusa*) or it is a special crop grown and reaped at successive intervals, the plants not being allowed to form fruit. For fodder purposes it may even be sown on the same land two or three times within one year, and the soil is thereby improved rather than injured, as the pulse both cleans it of weeds and adds largely to its nitrogenous property.

Bhusa.

Chemistry.—With regard to the chemistry of horse-gram, Church (*Food-Grains of Ind.*, 162) gives the following analysis. In 100 parts, unhusked :—water 11·0; albuminoids, 22·5; starch, 56·0; oil, 1·9; fibre, 5·4; ash, 3·2. The nutrient ratio is 1:2·7, and the nutrient coefficient 83. [*Cf. Leather, Agri. Ledg.*, 1901, No. 10, 360.] The seeds are used medicinally in the Panjáb. Arjun (*Bomb. Drugs*, 40) says a decoction of *D. uniflorus* is employed by the Natives in certain diseases of women. [*Cf. Kanny Lall Dey, Indig. Drugs*, 1896, 118.] The seeds are moreover reputed to yield an oil.

Nutrient Ratio.

Medicine.

Oil.

Area.—As already explained, the official statistics under which this pulse should be recorded are referred to two sections :—"Gram" and "Other food-grains including pulses." It seems likely that the former denotes *Cicer arietinum* and that the latter includes the horse-gram. In 1905-6 the total area in British India under gram came to 11,024,170 acres, and the others to 28,022,722 acres. The available information regarding the production of gram will be found under *Cicer*. It need only be added that of the area devoted to the "others," a fair proportion, especially in Madras and Bombay, would be the present pulse. The following may be given as an analysis, province by province, of the areas under "others" :—6,284,192 acres were in Madras; 4,451,000 in Bengal; 4,248,816 in Agra; 2,417,785 in Oudh; 4,743,321 in the Central Provinces; and 2,575,116 in Bombay. These returns give, therefore, the only possible

Plain*, 228-9; Cooke, *Fl. Pres. Bomb.*, i., 381. The *sím*, *makhan-sím*, *sem*, *popat*, *borboti*, *gheea-sím*, *panch-sím*, *molab*, *urohi*, *uri*, *kechu*, *chimi*, *katjang*, *pávta*, *wall*, *vál*, *paruti*, *válpapri*, *mochai*, *bili manavare*, *mutcheh*, *alsanda*, *annapa*, *avare*, *pe-byá*, *pe-bazon*, *pe-gyi*, *pe-lun*, etc.

Cultivated Forms.—Wild and cultivated throughout India; it ascends the Himalaya to 6,000 or 7,000 feet in altitude. De Candolle (*Orig. Cult. Plants*, 346) says its culture dates perhaps from three thousand years, but that he can find no trace of its being early diffused in China, Western Asia or Egypt. Hosie (*Rept. Prov. Ssu'ch'uan, China*, 1904, 11) says it is called *ssu chi tou* (four-seasons bean) because it is cultivated throughout the year. Henry (*Econ. Bot. China*, 12) remarks that its Chinese name is *pien-tou*, and that there are two varieties, one with purple, the other with white flowers. So also in India there are two cultivated varieties, though these have not been distinguished in the *Flora British India*. Prain defines them as follows:—

Two Forms.

Var. Lablab proper; pods longer, more tapering at point, seeds with long axis parallel to the sutures. This is *D. Lablab*, Linn., *Sp. Pl.*, 1019; *D. lignosus*, Roxb., *Fl. Ind.*, iii., 305 (non Linn.).

Var. lignosus (Linn. sp., non Roxb.); pods shorter, more abruptly truncated at end, seeds with long axis at right angles to the sutures. Roxburgh, it will thus be observed, reversed the incidence of the Linnæan names.

Prain (*Journ. As. Soc.*, l.c. 430) remarks that the epithet "*lignosus*" is much more appropriate when applied to "*Lablab*" than when given to the plant to which Linnæus assigned it. "Roxburgh identifies with his '*Lablab*' the plant figured by Rumphius (*Herb. Amb.*, v., t. 136), in an identification that is obviously just; Linnæus gives this very figure as one of the types of his *D. lignosus*."

History.—Adams (Comment. in *Paulus Aegineta*, 1847, iii., 470) observes that Serapion, on the authority of Aben Mesuai, describes the properties of a climbing plant which he calls *lebleb*. Adams accordingly adds that there is every reason to suppose the *lebleb* of Serapion and Avicenna was *Dolichos*. De Candolle (l.c. 347) gives, on the other hand, an account of the origin of the word *lubia*. He remarks that it possibly comes from the Greek *lobos*, which means any projection, like the lobe of the ear, a fruit of the nature of a pod, etc. Asa Gray (*Scient. Papers*, i., 353), reviewing De Candolle, comments that "the name (*lubia*) seems to be clearly referable to the Greek. It has not been traced earlier than to Jahia Ebn Serapion—an Arabian physician of the 9th or 10th century—whose work '*De Simplicibus*,' compiled chiefly from Dioscorides and Galen, was translated into Latin in the 15th century." The word "*lobiyá* (king of beans)" occurs among the list of autumn (*kharif*) crops known to Akbar, and lexicographers would seem to regard the word *lubia* as of Persian origin. At the present day, in Upper India, it would appear to be applied to two plants, *Vigna* and *Dolichos*. Considering the time these plants come into season, it seems probable that the *lobiyá* of the *Ain-i-Akbari* (Blochmann, transl., 63) was *Vigna Catjang* (p. 1107). I accordingly restrict the word *lobiyá* to that plant; and, if this be correct, it is probable that none of the species of *Dolichos*, were known to the Persian writers of classic times. Moreover, no species of *Dolichos* would seem to have the properties attributed to the *lebleb* of the Arab writers. This reasoning would accordingly assign to the species of *Dolichos* an indian origin, an opinion confirmed by the fact that both *D. biflorus* and *D. Lablab* are met with as wild species, the cultivated races of which bear many purely indigenous names. In the *Taleef Shereef* (l.c. 147) "*Lobeia*" is mentioned as a common culinary grain.

Wild in India.

engal.

CULTIVATION.—**Bengal and Assa**.—*Lablab* is not a regular agricultural crop in any part of India. It is more correctly speaking a garden plant, and is trained to form arbours over the doorways of village huts. For example, the Director of Land Records and Agriculture says that different varieties are cultivated all over Bengal as garden vegetables. The Rev. Dr. A. Campbell tells us of Chota Nagpur that it is largely cultivated

PROVINCIAL PRODUCTION

OLIC O
LA LA
Cultivation

but that he never found it wild. Basu (*Agri. Lohardaga*, 79) remarks that it is sown in July to August. It is allowed to climb on trees or hedges, and the green pods are procurable in January to March. Mukerji (*Handbook Ind. Agri.*, 1901, 263) writes that the time for sowing is July (the quantity of seed per acre being 5 to 8 lb.) and that the time of harvesting is January and February, the yield being 250 to 400 lb. per acre. Banerji (*Agri. Cuttack*, 1893, 118-9) observes that it is planted in specially prepared holes or pits about the middle of June. The plants flower in November-December and the crop is obtained in February-March. Speaking of Assam, it is met with not only in the valley proper but also in the Naga, Garo, Khasia hills and Manipur—each locality having distinctive indigenous names for it. About 45 seers of pods are obtained from each plant in the year, and the average price is six pice a seer.

Seasons.

United Provinces.—Duthie and Fuller (*Field and Garden Crops*, pt. ii., 23) observe that in these provinces this pulse is commonly grown along the borders of tall crops and allowed to twine itself on the plants standing on the margin. Castor-oil is a favourite support. It is never grown as a field crop by itself, as it requires artificial support. Duthie (*Fl. Upper Gang. Plain*, 229) remarks that it is extensively cultivated for its pods, which are harvested in the cold season.

Upper
India.

Central Provinces and Berar.—It is often met with as a field crop in these provinces. Two forms are seen, one with white, the other with dark purple flowers. They are usually grown in lines through the fields, special supports being furnished, or they are left to crawl and to take such support as they can from the stubble of the associated crop.

Two Forms.

o bay.—There are several very distinct varieties or races of this pulse met with in Western India. These might be grouped into garden and field varieties. The former (as with the other provinces) can be spoken of as late *kharij* plants, since they come into season about December to January. Mollison (*Textbook Ind. Agri.*, 1901, iii., 80) furnishes an interesting account of this Bombay crop. He says that the form known as *surti pāpdi* is grown extensively in gardens in the Surat district. The beans are plucked early and eaten like French beans. The field variety of Surat is a second crop, bitter to taste and called *kadva vāl*, but in Southern Gujarat there is still another field form that has smaller pods and is drilled with rice and *tuver* (*Cajanus indicus*) during June-July. The principal crop is the *rabi*, which usually follows rice. It is sown alone or with castor-oil (the dwarf variety). *Vāl* is also grown among other pulses subordinate to *juar* or *bājri*. When the *juar* is reaped, a long stubble, 3 to 4 feet high, is left. This, with the vigorously growing castor-oil and *tuver*, affords support to the climbing *vāl*, and heavy successive crops of green beans may be plucked from November to March. The most suitable soil for *rabi vāl* is a heavy black clay retentive of moisture. When the leaves turn yellow and begin to drop off, the crop of ripe beans may be gathered. Mollison adds that on good soil and with careful cultivation 1,300 lb. of pulse and an equal weight of useful fodder per acre may be obtained, off the same field from which a crop of rice has been previously harvested. And this is supplementary to the supply of green pods that may have been collected as a fresh vegetable in the early months of growth. The Department of Land Records and Agriculture, Bombay Presidency, in their *Season and Crop Report* for 1903-4, gave 94,993 acres as the total area under this crop; and for 1905-6,

52,969 acres, with, in addition, 232 acres in Sind. The chief localities are usually—in Gujarat, Surat; in the Deccan, Poona; in the Karnatak, Belgaum and Bijapur; in the Konkan, Thána and Kolába.

Madras and Mysore.—Very little can be said regarding this crop in South India except that it is grown in gardens, being sown from June to August, and reaped from October to March. In the *Dictionary* will be found a selection of passages from the *Madras District Manuals*, and these may be consulted. Rice (*Mysore Gaz.*, 1897, i., 112) says it is always cultivated with *râgi* (*Eleusine coracana*). When the plant is cut it is exposed for one day to the sun and then beaten with a stick to separate the seed. [*Cf.* Buchanan-Hamilton, *Journ. Mysore, etc.*, i., 103; ii., 220, 290, 314, 323, 384.]

Bur a.—Mason (*Burma and Its People*, 1860, 466, 768) says “the Burmese and Karens grow several varieties of one or two species of *Lablab*, which occupy the place of kidney beans in Europe.”

FOOD AND FODDER.—It is difficult, if not impossible, to estimate the actual area under a garden crop such as the present. It is grown all over India more or less, but is comparatively rare in Northern India, becomes abundant in Central, Western and Southern India, and is extended through Bengal and Assam to Burma. As already indicated, it is grown as a green vegetable (corresponding very largely with French beans and as a ripe pulse with the broad bean) and also as a fodder crop. The ripe pulse is eaten by certain classes only or is employed as a cattle food. Church (*Food-Grains of India*, 1886, 161, t. 31) gives the following, deduced from the chemical analyses of the ripe bean:—Nutrient ratio 1:2.5, nutrient value 80. The percentage of albuminoids is rather variable. Leather, in an article on Cyanogenesis in Plants (*Agri. Journ. Ind.*, 1906, i., pt. iii., 224), states that he has obtained prussic acid from the seeds of *vál* by simply allowing the crushed seeds to remain a few hours in cold water. [*Cf.* Leather, *Agri. Ledg.*, 1901, No. 10, 361; 1903, No. 7, 152, 155, 166.]

D.E.P.,
iii., 18.
Durian.

DU IO I T I U ,DC.; *Fl. Br. Ind.*, i., 351; Gamble, *Man. Ind. Timbs.*, 1902, 92; Brandis, *Ind. Trees*, 78. **MALVACEÆ.** The Durian, *duren*, *duyin*. A large tree native of the Malay Peninsula, though wild and cultivated in Tenasserim.

The earliest European mention of this fruit appears to be that of Nicolo Conti (*Ind. in the 15th Century* (ed. Hakl. Soc., Major, transl.), 9), and the first botanical drawing of it would seem to be that given by Jacobus Bontius, 1629 (*Hist. Nat. et Med. Ind. Or.*, in Piso, *Ind. Utri. re Nat. et Med.*, 1658, 118), though a crude representation of the tree and its fruit was given by Acosta (*Tract. de las Drogas*, 1578, 231). Garcia de Orta (1563, *Coll.*, xx.) very correctly describes the fruit as agreeable to some, repulsive to others. Linschoten (*Voy. E. Ind.* (ed. Hakl. Soc.), 1598, ii., 51-3, 68) remarks that no fruit in the world is to be compared with it, and Pyrard (*Voy. E. Ind.* (ed. Hakl. Soc.), 1601, ii., 366) affirms that the Indians “esteem this fruit to be one of the best and daintiest in the Indies.” A similar opinion is given by Mandelslo (*Travels*, in Olearius, *Hist. Muscovy, etc.*, 1639, 149), while Herbert (*Travels Ind.*, 1677, 334) mentions it among the fruits of Mangalore.

In size it is 10 inches by 7, has a cream-coloured fleshy aril or pulp enveloping the seeds. The smell is most offensive, but the fruit is highly prized, even by Europeans, when the prejudice against it is once overcome. [*Cf.* Wallace, *Malay Arch.*, 57.] The plant thrives well in Burma, where it is cultivated both in gardens in or near the villages and on the hillsides. The garden cultivation is largely in the hands of the Chinese, but the fruit produced is inferior to that from the hills. It sometimes sells in Moulmein at Rs. 20-30 per 1,000. [*Cf. Rept. Settl.*

UTRASUM OR RUDRÁK BEADS

L T TARIA
CA A O U
Carda om

Operations, Amherst Dist., 1893, 46-7.] It is very successfully grown in Ceylon, and attempts made to cultivate it near Calcutta, on the Nilgiris and at Madras, met with little or no success. Herbert's reference to it in connection with Malabar may perhaps indicate an early traffic in the fruit along the western coast of India, a circumstance that might account for its being described by Garcia de Orta and other early European explorers. [*Cf. Tavernier, Travels* (ed. Ball), 1676, ii., 287; Boym, *Fl. Sin.*, 1656, O (drawing after Acosta); Alexander Hamilton, *New Acc. E. Ind.*, 1727, ii. 81; Crawford, *Journ. to Ava*, 1834, ii., 219; Collingwood, *Rambles, etc.*, 1868, 271; Max and Bertha Ferrars, *Burma*, 1900, 87.]

LÆOCARPU GANITRU, *Roxb.*; *Fl. Br. Ind.*, i., 400; D. P., Gamble, *Man. Ind. Timbs.*, 113; **TILIACEÆ**. Utrasum Bead Tree, *rudrák*, *rudrákya*, *rudra-challu*, *rudráksha*. A large tree found throughout iii., 205. Rudrák.

The hard tubercled nuts are cleaned, polished or even stained, then made into the rosaries and bracelets worn by Brahmins and Sinyásis, and sold at such places as Benares, Allahabad and Hardwar. An effort has recently been made to organise a European trade in buttons and hatpins, etc., made of these nuts. In a letter from the Deputy Conservator of Forests, Lakhimpur, Assam, to the Reporter on Economic Products in 1900, the price for a maund of nuts in Dibrugarh was said to be Rs. 10, and Rs. 12-8-0 landed in Calcutta. Cooke (*Fl. Pres. Bomb.*, 1901, 152) remarks that the stones are imported from Singapore, where the tree is abundant. Sacred Beads. Price.

serratus, *Linn.*; *Fl. Br. Ind.*, i., 401; *jalpai*, *perinkara*, *meralu*, *utraccham*, etc. A rather small tree, occurring on the North-East Himalaya up to 3,000 feet in East Bengal, and in the evergreen forests of North Kanara and the west coast down to Travancore; also the low country of Ceylon. The fruit is known as "wild olives," the fleshy outer portion of which is eaten in curries by the Natives, and pickled in oil and salt like olives. D.E.P., iii., 206. Wild Olives.

L TTA IA CAR A OMUM, *Maton & White, Trans. Linn. Soc.*, 1808, x., 229-55, tt. 4, 5; *Fl. Br. Ind.*, vi., 251; **SCITAMINEÆ**. D. P., iii., 227-3. Cardamom. This is often designated THE LESSER CARDAMOM or THE MALABAR CARDAMOM, though it perhaps would be more correct to speak of it as THE TRUE CARDAMOM, the so-called GREATER CARDAMOM of most writers (*Anomum subulatum*, p. 65) being in reality a substitute for the true spice. The Cardamom is in the Indian vernaculars—*eláchi*, *iláyechi* or *choti* (small) *eláchi*, *illáchi*, *elechi*, *velloda*, *eláttari*, *elákai*, *eláki chettru*, *vittula*, *yálakki*, *yelaki*, *pamlat*, *pala*, *bhálá*, *ensal*, *enasal*, etc. In Sanskrit it appears to bear the following names—*upakunchika* and *elá*. Hence *elá-tari* means the grains or seeds of *elá*, and *elákai* the *elá* plant or root.

Habitat.—It is a perennial herb, with thick fleshy rhizomes, having erect leafy stems 4 to 8 feet in height, and long much-branched inflorescences which arise near the ground. It is indigenous to West and South India, growing in the rich moist forests of the hilly tracts of Kanara, Mysore, Coorg, Wynaad, Travancore and Madura. It is fairly extensively cultivated, within the regions indicated, at altitudes of from 500 up to 5,000 feet. Although there are no botanical specimens in the Kew Herbarium to support the opinion held by some writers, namely that it is also wild in Burma, there would seem little doubt that it is cultivated in that province, especially in the Bhamo district. Distribution. Wild and Cultivated.

Varieties and Races.—There are apparently two well-marked cultivated plants which it seems most to be regarded as deserving of separate recognition as at least varieties. In *Rees' Cyclopædia* (1819, xxxix., suppl.), the subject of *lettaria* is discussed and divided into two sections (a) *E. Cardamomum*, the Varieties. Two Forms.

Lesser or Malabar Cardamom, and (b) *E. major*, the Greater Oblong Cardamom. The authorities mentioned for the second form can hardly be accepted as definitely denoting any particular plant, but rather one or other of the many cardamom substitutes. Moreover, the so-called form designated *major* is spoken of as a native of Java. This subject might not have been here mentioned but for the fact that Schumann (in Engler, *Pflanzenr.*, 1904, iv. (46), 269) describes the Ceylon *Elettaria* as a distinct species, and cites the above authority (Smith in Rees, *l.c.*). Hooker (Trimen, *Handbook Fl. Ceyl.*, iv., 261) makes reference to *var. major* and gives it the Sinhalese name of *ensal*, the Malabar plant being *rata-ensal*. But Thwaites tells us (*Enum. Pl. Zeyl.*, 1861, 318) that after a careful comparison of growing specimens, he was satisfied that the round and long fruited cardamoms of commerce were not obtained from distinct species. The forms above indicated may therefore be stated thus:—

Malabar
Cardamom.

Var. α inor.—Leaves linear-lanceolate (much smaller and narrower than in β), the under-surface with a more or less complete coating of short white silky hairs. Inflorescence arising from the very base of the stems and creeping on the surface of the ground around the clumps, bracts shorter than the spikelets, acute. Fruits white, sub-globular, angled, somewhat coarsely veined.

The Lesser
Cardamom.

This is the Malabar cardamom of Indian planters, and is admirably figured and described by Bontius, Rheede, Sonnerat, Maton and White, and also by Ludlow. An unpublished plate by Roxburgh shows the creeping inflorescence, bracts shorter than the flowers and fruits elliptic. It is, therefore, typical of this plant. He gives no drawing of the next form. Bontius claims to have been the first person to study in Java the living plant and to distinguish the lesser from the greater cardamom. There are good examples of the present form in the Kew Herbarium from Kanara, the Wynaad and Ceylon—the last mentioned being less hairy than the Indian, but said by Trimmen to be “the Malabar cardamom of Ceylon planters.” The present plant is, however, the lesser cardamom; the one which follows, being much larger fruited, is very possibly, in consequence, the greater cardamom of the early writers, though as already stated that name has been frequently assigned to the Nepal cardamom (*Amomum subulatum*).

ysore
Cardamom.
The Greater
Cardamom.

Var. β ajor, *Thwaites, l.c.* 318; *Fl. Br. Ind.*, 251.—Leaves oblong lanceolate (broader and larger than in *minor*), usually quite destitute of silky hairs (one Ceylon sample in Kew is sparsely hairy). Inflorescence at first erect, bracts larger (longer) than the spikelets and obtuse or apiculate. Fruit oblong, fusiform, minutely veined, twice the length of that of *minor*.

Wild and
Cultivated

This is the Mysore cardamom of planters, who speak of two forms of it, viz. *uru* (cultivated) and *kadu* (wild). It is a larger, more robust plant than the so-called Malabar. In the Kew Herbarium there are, however, examples of it from Malabar, Palghat, Ceylon, Mauritius and the Gold Coast. Thwaites and Baker say it is indigenous in Ceylon. Bontius observes that it occurs in the woods of Java, and he figures it as differing from the lesser cardamom by having an erect scape, longer pods and more hairy leaves. Some few years ago a large cardamom was regularly seen in the European markets and known as “Ceylon Cardamom.” At the present day the Malabar form is grown in Ceylon and has displaced the former plant. Thus a large-sized true cardamom has been a well-known plant for many years, and it would almost seem as if it had been carried even further afield by cultivation (perhaps because hardier), than the smaller and finer spice. This, therefore, very possibly may have to be accepted as the Greater Cardamom proper.

Ceylon
Cardamom.

Origin.

Origin.—Whether both these forms exist as wild plants and whether they originated respectively in Malabar and Mysore, as the planters’ names would denote, are points which more careful study in the future can alone determine. It has been suggested that the Malabar is simply a higher state of cultivation than the Mysore and Ceylon. The plants are at all events sufficiently distinct to justify belief that they have been known to the Indian people for many years. It is significant also that the earliest faithful illustrations (such as the admirable plates given by Rheede) denote in every particular the Malabar, not the Mysore plant. So far as can be judged, the Malabar Cardamom, three centuries ago, differed in no respect from that of to-day. But no botanist (if Bontius’ somewhat doubtful figure be disregarded) appears to have illustrated and described the Mysore form even down to the present time. These circumstances are opposed to belief in the ancestral stock of the Malabar having been the long-fruited Mysore plant. Lastly, Rheede makes no reference to either having been cultivated in Malabar

Not Cultivated.

during his time; on the contrary, he says the cardamom is not sown nor planted, but springs up after the forest is burned down. He then tells us of there being three forms on the mountains, thirty miles inland from Cochin and Calicut. It will be found below that Garcia de Orta, a century before Rheede's time, made practically the same observation except that he regarded the cardamom as cultivated. Rheede describes one of his plants as having round white fruits, another with longer but less valuable fruits, and the third pointed fruits, the least valued of all. It is thus quite possible that the two forms, the small round fruit and the elongated fruit, were both known to Bontius, as also to Rheede. Sonnerat, a century later, gives two admirable plates, one being undoubtedly the Malabar cardamom, and he speaks of its fruit as a round capsule with three angles or edges lengthwise, having many parallel nerves and divided within into three compartments, each with several black seeds. The Ghats (or coast mountains) of Malabar take the name, he adds, of "The Mountains of the Cardamom," from the abundance there of the plant, which grows wild and supplies the cardamoms of all the Indies. Farther on Sonnerat (*Voy. Ind. Or.*, 279) discusses a greater cardamom (under the name of *Amomum angustifolium*)—a plant which he says is wild in the island of Madagascar. It grows on marshy soils, and its cultivation has been undertaken in Mauritius. It has a reddish capsule, oval-oblong, almost triangular. He does not describe nor figure it as winged, like the "*bungali elachi*"—the greater cardamom of the Calcutta shops (see p. 65)—though it is doubtless another of the many large fruits of which *A. maximum* of Java, the nutmeg cardamom of the Arabs (*Pharmacog. Ind.*, iii., 436) and of the Bombay shops, as also the prickly cardamom of Tavoy—*A. xanthioides*—are cardamom substitutes that have been all at times designated Greater Cardamoms. [*Cf. Kew Mus. Guide*, ii., 9.]

istory.—It is hardly necessary to attempt to furnish a detailed account of the early history of the Cardamom. Garcia de Orta was the first European who studied the plant practically in India (1563, *Coll.*, xiii.). He speaks of two kinds—*major* and *minor*, furnishes an accurate series of Indian and Ceylon vernacular names, and mentions that the Arabs knew the two forms and had separate names for them. It is highly unlikely that the Nepal greater cardamom was carried to the west coast of India to be traded in by the Arabs at the time of Garcia's residence there, and it is certainly not so traded in to-day. Far more likely is it, therefore, that he alluded to the large and small fruited forms of *Elettaria*, above described. But there are many surprises for the student of this subject, in Garcia's brief account. He says it was cultivated. Both varieties are found in India, chiefly in Calicut as far as Kananor and other parts of Malabar and in Java. An especially large kind, but less aromatic, was produced in Ceylon and carried to Hormuz and Arabia. This was doubtless the *var. major* above discussed—a plant also said to be indigenous to Ceylon. But it is significant that Garcia, after apparently a personal study of the plant and of the fruit, should have arrived at the emphatic opinion that the *elättari* or *eläch* of India was the cardamom of the Greeks, whatever that may have been (see Capsicum, p. 264). He says that the descriptions given by Galen, Dioscorides and Pliny do not agree with the Indian cardamom. Bontius, while agreeing that Pliny was wrong, takes exception, however, to Garcia's statement that it is cultivated and bears the fruits on the top like peas. In Java, Bontius says it is produced abundantly and its fruits are formed near the ground while the greater cardamom produces its fruits above. In this view Bontius and Garcia were practically followed by Clusius and the two Bauhins. Until the appearance of Rheede's account (approximately 100 years afterwards), the plant could not, however, be said to have been fully known in Europe. It is surprising that errors committed by Commelin (*Fl. Malab.*, 1696, 18), Burmann (*Thes. Zeyl.*, 1737, 54) and Linnæus (*Fl. Zeyl.*, 1747, 2) should have continued to disfigure the literature of the subject, during the succeeding century or so, until Maton and White established the genus *Elettaria*.

Situation.

CULTIVATION.—Few recent writers have furnished either so interesting or so detailed accounts of the cardamom cultivation as those written during the first decade of the 19th century by White for Malabar and Buchanan-Hamilton for Mysore. It would occupy much space to deal with the centres of chief production separately, or the variations in method of cultivation and preparation that prevail. All that can be here attempted is a brief review of the salient points collectively. A fairly deep rich loamy soil, resting on rock, seems indispensable, and if possible this should be within undulating land, not too remote from running water. Shade and a humid atmosphere are essential—it luxuriates in mists and fogs and cooling sea-breezes. Northern and western exposures are in South India accordingly considered the best. But all these conditions are not often conveniently combined, and hence the localities of successful production are somewhat restricted. Even within Malabar there are only certain tracts that can be spoken of as specially favourable.

1. **Forest Production.**—The system described by Rheede still prevails. Small plots of land within the forests (called *elá-kandies*) where the wild or acclimatised plant is known to exist are cleared during February and March. The brushwood is cut down and burned, and the roots of powerful weeds torn up so as to free the soil. The shade, if too dense, is regulated by a certain percentage of trees being felled, thus admitting diffused sunlight; and, curiously enough (from the most ancient times to the present day), the disturbance or shaking of the soil, by the fall of heavy timber on it, is in itself deemed beneficial. At all events, soon after clearing, cardamom plants spring up all over the prepared plots; but if any reason exists for doubting the abundance of the future crop, young plants are deposited in the soil at the required distances apart. The plots are then left alone for a couple of years, and by that time the cardamom plants will have eight to ten leaves, and be a foot in height. In the third year they may be four feet in height. In the following May-June the ground is again weeded, and by September to November a light crop may be obtained. In the fourth year weeding is again given, and if the cardamoms are found growing nearer than six feet apart, a few are transplanted to new positions. A full crop is now obtained, and the plants may bear for three or four years; that is to say, the life of each plantation is eight or nine years. The seasons in Malabar are a little later than in Mysore, and according to some reports a full crop may even be obtained in the third year. It is also believed that above 2,000 feet the cardamoms grown are of a better quality than below that altitude.

Plants may be raised from seed or by division of the rhizome. They may be prepared in special nurseries. In about a year the seedlings will be a foot in length, and are then ready for transplantation. When raised by division of the

rhizome, it should be seen that each cutting contains at least three perfect shoots. Holes a foot deep and six or seven feet apart each way are now dug all over the specially cleared plot or garden, and the seedlings or sets are deposited within these, but they must not be buried too deeply as they are liable to rot off. The flowering season is April to May. It is a good plan to bank up around the clumps all leaves and rubbish obtainable, since this helps to support and encourage the growth of the creeping racemes. If at this stage the flowering branches (racemes) get submerged, the soil is washed away, the roots exposed, and the flowers and fruits ruined with the water and mud. The fruit should not be allowed to ripen fully, as the capsules will then burst and the seeds be lost. They should be collected just as they begin to turn from green to yellow. In August and September they swell, and by the first half of October have usually attained the desired degree of ripening. The crop is accordingly gathered in October and November, and in exceptionally moist weather the harvest may be protracted into December. A dry day is best for harvest. The scapes or shoots bearing the clusters of fruits are broken off close to the stems and placed in baskets lined with fresh leaves. At night time they are carried to the temporary hut used by the men. After partaking of a meal and often working far into the night, the men separate carefully the capsules from the shoots, placing them as removed into a pit dug on purpose in the middle of the hut. In the morning the women arrive and carry the produce off to the homestead, where the further treatment is conducted. The fruits are spread out on carefully prepared floors, sometimes covered with mats, and are then exposed to the sun. At night they are carried within doors, as also during showers. Four or five days of careful drying and bleaching in the sun are usually enough, but in rainy weather artificial heat may be necessary, though the fruits suffer very greatly in colour when this course has to be resorted to, and are in consequence sometimes bleached with steam and sulphurous vapour or with *ritha* nuts (see p. 979). The sun-dried cardamoms are the best, and in trade are spoken of as "green cardamoms." The capsules are now rubbed by the hand or shaken within mats, in order to brush off the pedicels, calyces, particles of dust, etc., then are winnowed, hand-picked and assorted according to size, colour and degree of ripeness, etc.—for on the racemes there must always be a percentage of overripe as also of underripe fruits.

2. **Agricultural Production.**—Very little of a satisfactory nature can be learned of the systems pursued or of the extent of agricultural production in India. Mollison (*Textbook Ind. Agri.*, iii., 262) gives a brief but instructive account. He there speaks of the crop being extensively grown in the betel-palm and pepper gardens of the Sirsi and Siddapur Talukas of Kanara. It thrives under the same conditions of soil, etc., but by preference is grown in a cool, very shady garden with soil kept continuously moist. In Kanara the crop is chiefly raised from seed. The sowing season is September–October. But the beds require both shade and shelter from the sun and rain. If the seeds germinate too thickly they should be thinned out and the seedlings transplanted into rice seed-beds, but shaded by a temporary protection of palm-leaves. When four feet high and fifteen to eighteen months old, they may be carried to their permanent positions and finally transplanted from March to June, or again from September to October. Pits 18 inches square and 18 inches deep are dug in the same lines as the betel-palms and intermediate between two trees. Into these pits the cardamoms are deposited and supplied yearly, in March and April, with leaf-manure. They come into bearing but do not yield much during the first year after transplanting. The flowers appear somewhat irregularly in April and May, and the fruits form in June and July. The capsules are in season in September and October. Each should be severed from the scape and not plucked. If plucked, the pressure of the fingers may burst the capsule. After being dried in the sun for two or three days the fruits are hand-rubbed to remove the attached stalk and calyx. A too hot sun or too long exposure to the sun may dry the fruits (capsules)

too quickly and thus cause them to burst and thereby to be lowered in value. In a fully stocked betel-nut garden there can be 300 to 400 cardamom plants to the acre. A well-grown plant may yield up to half a pound of dry cardamoms. Light showers in April and May are favourable. The fruits are dried and bleached in particular ways, according to the market for which destined. The waters of certain wells are moreover supposed to produce particular colours and flavours. The system above briefly reviewed is that also followed in Mysore—viz. production in betel-palm plantations.

AREA AND YIELD.—Ludlow observes that when from one stem four scapes are thrown out, the crop is regarded as full; if only three, it is a three-fourths crop; if two, a half crop; if only one, a quarter crop. "One raceme will have from eight to fourteen branches, and each branch from three to six pedicels. When the crop is good, the branches are close together; when bad, the racemes are long and the branches far apart." "Fruit is occasionally borne on the upper part of the stem, but this is very rare." He further estimates that a garden of 484 square yards in area would give on an average 40 seers of green cardamoms or 10 seers of dry fruits. The actual yield, as published, by plantations is variously stated, and seems to range so greatly that the differences would be best accounted for by supposing that returns of green fruits had been contrasted with dry, or that they denoted diversities in stock rather than of soil or methods of cultivation. In Mysore 28 lb. are spoken of as the yield per acre, and in Ceylon 170 lb., although even as much as 400 lb. have been mentioned. In a circular issued by the Madras Government in 1903, the yield per acre is recorded as from 11 lb. to 700 lb. Omitting the extremes, the more important returns given in that circular were Dindigal, 93 lb.; Palni, 125 lb.; Kodaikānal, 250 lb.; Wynaad, 42 lb.; Calicut, 50 lb.; Uppinangadi, 49 lb.; and Kasaragod, 56 lb. The difference between green and dry pods has been expressed as four to five bushels shrinking to one.

Very little can be stated regarding the total area under cardamoms. There may be said to be two Indian areas, viz. the Madras and Bombay Presidencies. The former, which is often given the wider signification of South India, may, so far as cardamoms are concerned, be split up into (a) under British Indian Administration, or Madras proper; (b) the British Administration of Coorg; (c) under the Native State of Mysore; and (d) under the Native State of Travancore. Such particulars as are available regarding these areas are disjointed, and often do not refer to one and the same year. Cardamoms are of course returned under "spices and condiments," and it is only occasionally that the provincial details for these are forthcoming. The Madras Government published, however, in 1903, a statement of the cardamom area for the year previous. This showed *Madura*—(Dindigal, Palni, Periyakulam, and Kodaikānal)—as possessing 3,714 acres with a yield of 649,281 lb. *Malabar*—(Chirakkal, Kottayam, Kurumbranāl, Wynaad, Calicut, and Ernad)—with 1,586 acres and 24,496 lb. yield. *South Kanara*—(Cundapur, Uppināngadi, and Kasaragod)—with 1,260 acres and 68,828 lb. yield. These give grand totals of 6,560 acres and 742,605 lb. In the small British Province of Coorg there are said to be about 60,000 acres retained for cardamom-growing, with, in 1902-3, 1,107 acres actually under the crop and say 50,000 lb. production. Turning now to the Bombay Presidency: in the official *Season and Crop Report* it is stated that the area in 1903-4 under cardamoms in the Kanara district came to 3,837 acres, or roughly half the area devoted to it in South India. If, for the purpose of comparison, the yield be accepted as on the same ratio, the production of Bombay should be 370,000 lb. In 1905-6 the area had increased to 4,573 acres.

The available information regarding Mysore and Travancore outturn is even more unsatisfactory than for the British districts. A few years ago the Travancore Cardamom Hills Planters' Association was established, a direct indication of the industry having in South India (as in Ceylon) passed to some extent into the hands of European planters. Of 1903 it has been said that 4,000 acres of cardamoms were owned by European planters. According to Mr. Bourdillon there are some 26,000 acres returned in Travancore as the cardamom area. Doubtless only a small proportion of that is in any one year actually under the spice. The produce of the Travancore plantations has been given as 650,000 lb., or just a little under that of Ceylon, which is obtained from an area of 10,000

PRODUCTION AND TRADE

L U
C ACA A
Rági

acres. The yield of the Mysore plantations would seem to be about 200,000 lb., and the cultivation would appear to be mainly in Kadur district.

The figures given above (if reliance can be put on them) would show a total production in all India of close on 2,000,000 lb. per annum. But that figure is mentioned purely and simply as suggestive, and must not be seriously accepted. In the *Annual Review of Forest Administration for British India*, issued by the Inspector-General, returns are given of cardamom-production within Forest Reserves. The volume for 1903-4 shows the value of the cardamoms exported to have been Rs. 3,37,000 as compared with Rs. 4,16,000 the previous year.

All India.

TRADE.—In the European markets cardamoms are spoken of under the terms “Shorts,” “Short-longs” and “Long-longs.” The “shorts” are from a quarter to nearly half an inch in length, and the “long-longs” an inch and over in length. The “long-longs” of modern commerce, it has been contended above, would seem to be the greater cardamom of early writers and the produce of the plant designated by planters the “Mysore or Ceylon cardamom.” They are finely ribbed, of a pale colour, and the seeds are grey or almost white, and shrivelled when dry. The “shorts” are the Malabar or Wynaad cardamoms, and accepted as the finest grades, the ripe seeds of which are black.

Trade.

Grades.

In most recent reports the statement occurs that overproduction has lowered very seriously the price. It would appear that in many of the abandoned coffee plantations of Coorg, cardamom and orange cultivation has been attempted, and with some degree of success. There has all over the cardamom area been for some years past a steady expansion of production, so that no doubt there is some truth in the story of overproduction. Still, it cannot be exactly said that the limits have been reached of the world's demand for this spice, and a fall in price is naturally the first incentive to increased consumption. The *EXPORTS* to foreign countries during the undermentioned years have at all events shown an expansion in quantity and a shrinkage in price. They were in 1899-1900, 191,120 lb., valued at Rs. 3,27,750; in 1902-3, 302,940 lb., valued at Rs. 4,16,242; in 1905-6, 295,390 lb., valued at Rs. 2,97,513; and in 1906-7, 202,374 lb., valued at Rs. 2,19,172. Of that traffic Bombay and Madras are the chief distributing ports. The coastwise returns, moreover, show that Bombay drew on Madras for its supplies. Of receiving countries the United Kingdom usually takes the first place, and is followed by Arabia, Aden, Germany, Turkey-in-Asia, Persia and Egypt. But perhaps the most surprising feature of the traffic is the fact that India *IMPORTS* cardamoms very largely from Ceylon. In 1903-4 these imports came to 269,132 lb., valued at Rs. 1,98,710, and in 1905-6 to 435,407 lb., valued at Rs. 2,58,083—as much in weight, but comparatively less in value than the corresponding exports. We thus learn that India is itself by far the most important consuming country for cardamoms in the world.

It has been established by Sir J. D. Hooker that *E. indica*, Gaertn., is the wild form of which *E. coracana* is the cultivated state. There would therefore seem no urgent necessity to discard for the present the time-honoured name by which this millet has been known to those interested in the food supply of India. The wild plant is said to occur all over the low country and to ascend to altitudes of from 5,000 to 8,000 feet on the Himalaya. It is distributed throughout the tropical regions of the Old World, but only introduced into the New. As an Indian cultivated plant, however, it

Wild and
Cultivated.

Names.	<p>might be more correctly spoken of as met with chiefly on the hilly tracts. With the hill tribes of Southern, Western and Northern India it is an important article of daily food. It is mentioned in <i>The Bower Manuscript</i>, of the 8th century, and is the <i>rájika</i> and <i>rági</i> of Sanskrit, and known in almost every vernacular language by names either derived from these or from what are possibly even more ancient aboriginal names:—<i>marud</i>, <i>mandud</i>, <i>makra</i>, <i>mandal</i>, <i>mandwa</i>, <i>meruya</i>, <i>nángli</i>, <i>náchui</i>, <i>nachiri</i>, <i>nágli</i>, <i>kodé</i>, <i>kodou</i>, <i>koda</i>, <i>kodra</i>, <i>kayur</i>, <i>kévar</i>, <i>kelvaragú</i>, <i>kutra</i>, <i>kurakan</i>, <i>rotka</i>, <i>rági</i>, <i>rágulu</i>, <i>tamidelu</i>, <i>taindulu</i>, <i>bávto</i>, etc.</p>
Origin.	<p>Varieties and Races.—There is perhaps little or no doubt that as a cultivated crop this originated in India. There are at all events three or four allied wild species regularly resorted to as articles of food in times of scarcity and famine. And moreover, of the cultivated plant there are in India several fairly distinct forms which almost of necessity denote antiquity of cultivation.</p>
Forms.	<p><i>E. stricta</i>, Roxb., has the spikes quite straight and more numerous; is in consequence a very productive plant. Roxburgh, speaking of Rajamundry (<i>Fl. Ind.</i>, i., 344), describes this as the <i>pedda</i> (or great) <i>solu</i> and says it is a later crop than the ordinary <i>ponassa</i> (or early) <i>solu</i>. He then adds that there is still a third and even more productive form than either, namely the <i>maddi ruba solu</i>. It requires a rich soil but gives an increase of 500-fold.</p>
Early and Late.	<p>Other writers refer similarly to early and late forms of this millet. Mollison (<i>Textbook Ind. Agri.</i>, iii., 56–60), for example, observes that in the Konkan and the Ghats districts the early crop is <i>halvi</i> and the late <i>garvi</i>; the former ripens about the end of September or early October, the latter at end of October or early November. It is therefore a rainy-season crop, and is usually sown on land that is too shallow or too poor for rice or too steep for terracing. But if the rainfall be well distributed it succeeds even on clay loams. The variability of the plant may in fact be regarded as a direct consequence of the class of soils on which grown. On stony and sandy soils the form that approximates most nearly to the wild state (<i>E. indica</i>) can alone be produced, and it is an inferior early crop. From that to the large and vigorous late forms of richer agricultural regions, an endless series of adaptations may be chronicled.</p>
Adaptations.	<p>CULTIVATION.—Bengal.—Until it is recollected that Bengal has large tracts of mountainous country it cannot be realised why this province holds the second position of importance in the cultivation of the present millet. The Bengal districts of production may be given here in sequence of value:—Darbhanga, Bhagalpur, Hazaribagh, Muzaffarpur, Patna, Gaya, Shahabad, Sarun and Monghyr have each from 250,000 down to 40,000 acres under the crop. The normal total acreage under it is about one million acres, and the outturn has been put at 10 maunds an acre. Buchanan-Hamilton (<i>Stat. Acc. Dinaj.</i>, 1833, 173, 182) describes the method of cultivation as a mixed crop with summer rice and <i>Cajanus</i>. In connection with Bihar he says it is grown as a summer crop broadcasted or transplanted, but of Bhagalpur there are two crops, one gathered in November–December, and the other three months earlier. Basu (<i>Agri. Lohardaga</i>, 1890, 63–5; also <i>Palamau</i>, 28–9) calls <i>márua</i> an upland cereal. There are two main varieties, an early red <i>lálká</i> and a late white <i>charká</i>; the former is a <i>bhádoi</i> crop which is harvested from August 15 to November 15, according to the season of sowing, the race of plant grown, nature of soil, and degree of rainfall. It is usually transplanted and has this advantage, that harvest can be deferred to suit the convenience of the cultivator. Col. J. J. Wood speaks of the <i>marúa</i> as widely and extensively grown in Chota Nagpur. Banerjei (<i>Agri. Cuttack</i>, 1893, 74–5) remarks that the <i>mandia</i> is an upland cereal and attains a height of 4 to 5 feet and bears grains of a reddish colour. The fields are prepared in May to July and the plants</p>

CULTIVATION IN INDIA

L U IN
C ACA A
Cultivation

raised in a seed-bed and transplanted with the first good showers. The crop is ripe August–September. The ears alone are cut off and the stems left in the ground to be browsed by the cattle. It will not grow on land that is inundated, nor even where the water lies for any time. It is essentially a crop of undulating well-drained soils.

United Provinces.—This millet is unimportant in these provinces. The normal area under it does not much exceed 200,000 acres. It is, in fact, within the hill tracts only that it assumes importance. Of Allahabad it is said *maria* or *makra* is sown on good soils near the villages sometimes with *juár*, more often alone and on manured land. The seed is broadcasted and ploughed in, but it may be transplanted from a nursery. Duthie and Fuller (l.c. 10), on the other hand, say of Jaunsar Bawar that it forms the chief article of food of the hillmen and is grown on the very poorest soil, often yielding a crop from mere stones and shingle. It is very rarely raised on the hilly country to the south of these provinces, where its place is taken by *kodon*. It grows, however, to a greater or lesser extent all over the provinces, and in the more fertile districts its cultivation is often attended with considerable care which results in a very large weight of produce. It suffers much from heavy rain, so much so that a good year for rice is generally a bad one for *mandua*. In Garhwal *mandua* is sown in April and reaped in October. It is often thinned out from one field and planted in another. In Kumaon it is cultivated both in ordinary agricultural lands and freshly cleared jungle. By October–November the crop is ripe and the ears are cut off, tied in bundles, and stacked for some twenty to twenty-five days, when they begin to ferment, and when warm are spread out and dried, then threshed. In Nepal there are two forms cultivated: one sown broadcast in May and June, the other raised in seed-beds and transplanted in June and July. Both forms grow and ripen in the rains. The broadcasted form is reaped in October, then transplanted in November. It is never, as a rule, sown on land suited for wheat, rice or sugar-cane.

Panjáb.—In this province *Eleusine* holds a very subordinate position among the foods of the people, since the normal area under it does not exceed 40,000 acres. Baden-Powell (*Pb. Prod.*, 1868, 245) says this is principally a hill product, but is also cultivated in Sialkot and a few other districts. In the Memoirs written by the Emperor Baber occurs a reference to *buzeh*, a kind of beer consumed by him on December 28, 1525, in or near the district of Sialkot. Mr. W. Coldstream, in a communication to the writer, says the grain of this pulse lasts in store much better than other grain. It is extensively grown in the Simla Hill States and comes into season in October. In the Kangra district it is an important food crop. In the Panjáb plains it is most frequently met with in the Karnál district, but chiefly in the Khádar. It is not uncommon in Jhang, especially in Chiniot. It is valued as a fodder crop, and may be cut two or three times in the rains.

Bombay and Sind.—Western India having extensive hill tracts, this millet becomes of considerable value. The normal area under it is about half a million acres. Dr. A. Gibson wrote a series of notes on the Agriculture of Western India (*Journ. Agri.-Hort. Soc. Ind. (Corresp. and Select.)*, 1845, iv., 54–5), and the remarks he makes under this plant are well worthy of careful consideration. The form *E. stricta*, he says, is met with in gardens below the Ghats, where alluvial soil and stream water are available, while *E. coracana* is the hill form, a smaller plant and much less productive. Mollison says that *nágli* occupies the fifth place among the Bombay cereals. In Kaira, Ahmedabad and Baroda districts of Gujarát, heavy crops are produced on highly assessed alluvial soil. Elsewhere the cultivation is chiefly confined to the poorer uplands of the Ghats. It is grown in districts of heavy rainfall, on land too light for rice. In Gujarát it is sometimes drill-sown, but is usually a mixed crop and most frequently transplanted. In the uplands of the Konkan and the Deccan it is often raised on steep land and is then broadcasted. For this purpose the soil is often burned with the brushwood (*ráb*), and the seeds are sown along with the ashes. The outturn varies so greatly that no general figure can be quoted. It may range from 700 to 1,600 lb. of grain and 2,000 to 2,400 lb. of straw.

Madras, Mysore, and Coorg.—South India is the chief region of *rági* production. The normal area under it in the British districts comes to close on two million acres, but in Mysore State alone the area is usually well over two million res, so that the total for South India might be put at 4½ million. districts of greatest importance are Salem, Coimbatore, Cuddapah, North Arcot, South Arcot, Trichinopoly, Anantapur and Vizagapatam, in the order enumerated. The Mysore districts are Mysore, Tamkur, Bangalore, Kolar, Hassan, Chitaldrug and Kadur. As with other economic products so with this millet, Buchanan-Hamilton (*Journ. Mysore, etc.*, 1807, i., 100-3, 285-6, 297, 369, 375-8, 403; ii., 103-4, 254) is a valuable writer. The Deccan Mussulmans, he says, call it *rágí*, the Tamil people *kevir*, and the farmers say there are three varieties—the *cari*, *kempu*, and *huluparia*. It is, near Seringapatam, customary to sow all three kinds in the same field. When the rains begin in June the field is drilled and *Eleusine* and *Cajanus* sown as a mixed crop. To appreciate the value of Buchanan-Hamilton's account of this millet, the passages indicated above must be consulted. They have, however, been reviewed and amplified by Lewis Rice (*Mysore Gaz.*, i., 1897, 107-12, a work which is probably more accessible than the original). *Rágí* is by far the most important single food crop of this State, especially on dry soils. It supplies the lower ranks of society with their chief food. The total area under food crops is usually $5\frac{1}{2}$ million acres, of which *rágí* alone occupies fully half.

Very little, however, can be added regarding the South Indian cultivation of this millet, to the account given in the *Dictionary*. Stuart (*Man. N. Arcot*, 1895, i., 267-8) says it is a favourite four-month crop, the grain being largely used by the labouring classes. It is not a dainty food, but very nutritious. There are four varieties. It is grown both on irrigated and unirrigated land, but most commonly in that which is commanded by a well. When dependent upon rainfall alone it is sown so as to get the benefit of one or other of the monsoons, that is from May to June and from October to December. Under wells and tanks it is sown and reaped throughout the year. Only the ears of *rágí* are cut as they ripen, and, being heaped together for two or three months, the grain is beaten out with sticks or trodden underfoot by cattle. It should be kept some months before being used.

MANUFACTURES.—Incidental allusion has already been made to some of the edible preparations of this millet. It has the advantage not only that it may be left standing on the fields till a convenient time for harvesting, but the grain improves by being stored and may be preserved for many years without either being attacked by insects or becoming mouldy. These are circumstances of the greatest possible value, and have justified this millet being accepted as the most desirable for storage against times of scarcity and famine. It is moreover one of the most productive of grains and one which will give a paying crop on soils from which hardly any other food can be obtained. It is essentially, therefore, to large tracts of India, the staple food of the poor, and, though not appreciated by fastidious tastes, is nevertheless wholesome. The seeds are milled and the "tailings" (the bran formed of the seed-coats) constitute an article of food with the very poor and one which is fairly largely used in the jails of South India. [*Cf. Agri. Ledg.*, 1899, No. 4.] The husked grain is reduced to flour and baked into cakes or boiled into puddings (about the consistency of blanc-mange). This is often improved by being cooked along with one-third rice or *cholam* flour. Church (*Food-Grains of Ind.*, 1886, 89) has given attention to the chemical composition of both the grain and the tailings of this millet. Lastly, numerous writers allude to a beer and spirit prepared from the grain. One of the earliest and most curious passages on this subject is that given by Baber (*Memoirs*, 283, 294). This has already been alluded to, but the Emperor's remarks regarding the people of Sewad, Bajour and the neighbouring countries, who make a peculiar kind of *buzeh* (or beer) may be here quoted:—"There is a substance which they call *kím* composed of the tops of certain herbs and of various drugs. They make it round like a loaf, and then dry and lay it up. This *kím* is the essence from which the *buzeh* is made. Many of the potions composed of it are wonderfully exhilarating, but they are terribly bitter and ill-tasted. I had thought of taking this *buzeh*, but, from its extreme bitterness, was unable to swallow it: I then took a little *májún*." The Emperor repeatedly refers to his special drinking-parties, held not infrequently on board pleasure boats, and the gusto with which he narrates his experiences might easily enough have originated the English expression "bousing"—or deliberate intoxication with *buzeh* (beer). Mr. (now Sir Arthur) Wollaston tells me that *buzah* or *buzza* is Turkish, meaning a drink prepared from corn, and that it had been adopted into Persian with the meaning ale or beer. Shaw (*Travels*, 1757, 407) says: "Besides the use that is commonly made of barley to feed their cattle, the Egyptians, after it is dried and parched, make a fermented

WHITE SILK-COTTON TREE

I D DRON

Kapok

intoxicating liquor of it, called *bouzah*, the same, probably, [with the *oinos krithinos* of the ancients. This is very copiously drunk by the lower rank of people." (See remarks regarding *boza* and *múra* under *Cannabis sativa*, p. 257). In the Maráthá country the fermented liquor of *Eleusine* is called *bojah* or *bojali*, and 100 years ago it was perhaps more extensively made than to-day. Hove (*Tours in Gujarat*, etc., 1787, 21) speaks of the adulteration of *mowra* liquor with *Acorus* root. The liquor in question may have been the *marua* (*Eleusine*), or of course it might have been *mahua* (*Bassia*), which Hove in another passage calls *mawra*. In Kumaon it is called *daru* (*Bassia*, see p. 119). A similar beer is made here and there all over the Indian area of *Eleusine*, and throughout the Himalaya from Kashmir to Sikkim. It is, however, displaced in Assam and the Naga hills by the beer made from *Coix* (*dzu*, see p. 396), also more recently by European alt Liquors (see pp. 757-8).

Area, Yield and Trade.—The total area for all India devoted to this crop averages from $5\frac{1}{2}$ to $6\frac{1}{4}$ million acres, of which nearly two-thirds are in South India. It is possible that were returns for Hyderabad (Deccan) and other States (not at present obtainable) added to the returned area, the grand total would not be far short of 7,000,000 acres. The yield is variously stated at from 5 to 10 or more maunds per acre. If a yield of 400 lb. be accepted as a safe mean average, expressed to the estimated acreage that would show an annual production of 25,000,000 cwt. of edible grain—a by no means insignificant item in India's food supply. To South India, which approximately consumes two-thirds of that amount, it is an exceedingly important article of diet. There is no mention of this millet in the foreign trade of India, so apparently the produce is entirely consumed within the country.

Loquat.

A tree indigenous in China and Japan: cultivated in Northern and Eastern India, and, like the *kitchi* and other Chinese plants, is most successfully grown in Assam. The fruit is much appreciated and comes into season about the middle of March, and may be purchased almost everywhere in India for six weeks or two months thereafter.

IOD N ON ANF ACTUO UM, DC.; *Fl. Br. Ind.*, i., 350; *MALVACEÆ*. This is the WHITE SILK-COTTON TREE, the KAPOK TREE of the Dutch, and in India is the *safed simal*, *senibal*, *katan*, *hatian*, *sham-eula*, *katsawar*, *ilavam*, *buruga*, *pur*, *kadami*, *dúdi mara*, *pania*, etc. Is a moderate-sized tree fairly plentiful in some parts of Western and Southern India and Burma, but doubtfully indigenous. Largely planted around villages and temples, and if a demand arose for it, of sufficient importance, its production might be greatly extended.

iii., 58-64.
apok.

History.—Jacobus Bontius (*Hist Nat. et Med. Ind. Or.*, in Piso, *Ind. Utri. re Nat. et Med.*, 1658, 105) was perhaps the earliest author to figure and describe this tree. He lived in Batavia in 1629, but it is not quite clear whether his *Abor Lanigera* (which he identifies with the *Gossampines* of Pliny (bk. 12, ch. 10, 11) had been seen by him in the Malaya or in India. His engraving though quaint, is unmistakable, but he describes the tree so minutely that without his figure even, there would be little difficulty in identifying the plant as *Eriodendron*. The oblong pods produce wool that cannot be carded as it is too short, but throughout India it is sought for as a material with which to stuff couches and cushions. It is in p sing worthy of remark that Bontius makes no mention of the true cotton, nor of the red-silk-cotton tree, both of which he must have seen India at least. From this silence it may be inferred that the *Abor Lanigera* was a Batavian tree. Rheedé (*Hort. Mal.*, 1682, iii., tt. 49-51) gives a sketch of it not unlike that of Bontius, but his other pictures might be described as quite as

good as many others produced up to two centuries later. He tells us that it occurs everywhere in Malabar and bears fruit in January and February and puts on fresh leaves in March and April. Hence if it be not indigenous to India it must have been introduced at a very early date.

Properties and Uses.—From the bark a medicinal GUM is obtained ; the wood is employed as a TANNING material for leather, and from the bark an inferior bast FIBRE is sometimes prepared. The seeds yield 28 per cent. of an OIL that much resembles cotton-seed oil, and the cake is found to be a highly beneficial cattle food. The oil is used in Holland as food and in the manufacture of soap. It dries more rapidly than cotton-seed oil. The WOOD is of poor quality, and is only of use in the construction of toys. But interest in the plant may be said to be concentrated in the FLOSS or SILK-COTTON obtained from the fruits. This is known to commerce as *kapok*, a Dutch-Malay word derived apparently from the Sanskrit *karpāsi* just as the most general Indian name for the tree is *hatian*, a word derived from the Arabic *katan*, and thus its names suggest the similarity of the floss to cotton. Gamble (quoting Trimen) very properly remarks that the *kapok* cotton is obtained, not from the testa of the seed but from the wall of the capsule. This is perhaps more than a botanical peculiarity, and doubtless accounts for some of the characteristics of the floss, which is used in nature as a packing material for the seeds, but is not, like cotton, formed from the seeds themselves. *Kapok* is of better quality than the corresponding cotton of *Bombax* as it is more elastic, and when used for upholstery is less liable to knot. Both Bontius and Rheede (as already shown) mention that the cotton is used in stuffing couches and cushions and is held in great esteem because of its softness. Rumphius (*Herb. Amb.*, i., 196, t. 80) tells us that in his time (1750) the tree was very abundant in Java and had been carried from there to most of the Malayan islands. He further remarks that although the fibre is too short to spin, it is largely used for filling cushions and has the advantage of not being, like ordinary cotton, easily rolled into balls. During the Colonial and Indian Exhibition of London (1885-6) I showed samples of Indian *kapok* and other silk cottons and urged the claims of this particular fibre to attention. It is only within the past decade or so that the subject seems to have attracted the notice of Indian merchants as being something more than a curiosity. It would thus almost seem as if the plant had been in India more highly esteemed over two centuries ago than to-day. And it is precisely in upholstery that the fibre has in Europe come into prominence. Fairly largely exported from Java. In 1898, for example, the traffic came to 51,919 bales, and in 1901 to 74,123 bales. Of the last-mentioned year's consignments 45,631 bales went to Holland, 23,192 bales to Australia, and 5,300 bales to the United States. The supply received by Holland in 1903 was 51,918 bales. Ceylon would also appear to have commenced to export this fibre. India exports none, and the local demand even is insignificant, *Bombax* floss (see p. 168) taking its place.

According to some writers the increasing demand for this floss in Europe necessitates belief that it is being used for textile purposes. But it is too fine, light, smooth and slippery to be easily spun, unless used as an admixture with other flosses. It is reputed to be employed in Bordeaux for the manufacture of soft non-conducting felts. Attempts have unsuccessfully been made to blend it with the fur fibre of the coney and hare, in the production of the "nap" of silk hats. The Kapok Supply Company of London announce that they are now using it very largely in the construction of life-belts, lifebuoys, etc., and that it is regarded as superior to cork or hair since much more buoyant, softer and cheaper. Life-jackets may be padded with *kapok* and rendered waterproof by being lined with waterproof cloth. It is, however, as already mentioned, in upholstery mainly that *kapok* has found its most important use. It is largely worked up for cushions, pillows, chairs, bedding, etc., in Holland, Germany, Australia and the United States, but only to a comparatively small extent in England. For these purposes its non-hygroscopic character, its softness and resiliency render it peculiarly suitable. It is also less absorbent, less liable to harbour insects, and can be sterilised by heating at least three times without being seriously damaged. With so much to recommend it, the apathy preserved in India is remarkable ; but there is this to be said as possibly explanatory, viz. that so far the Indian floss has fetched less than that of Java. This is by some believed to be due to defective methods of collecting, cleaning, packing, pressing, etc. ; by others, and perhaps with greater reason, as due either to climate or stock of plant grown. Certainly the opinion advanced by some writers (in the Indian press particularly) that

kapok is but a Dutch name for the well-known *semal* cotton—the floss of *Bombax*—is quite erroneous; the floss of *Eriodendron* is far superior to that of *Bombax*, and the two must never be confused with each other. The best qualities of Java *kapok* are said to fetch from 7d. to 9d. per lb., the Indian not much more than half these sums. The double profit of floss and oil-seed should make the cultivation of *kapok* profitable in all hotter moist tracts of India that possess an insular climate. The subject is being vigorously taken up in both the French and German colonies, and is well worthy of special consideration in India. [Cf. Watt, *Select. Rec. Govt. Ind.*, 1888, 329–39; Moodeen Sheriff, *Mat. Med. Mad.*, 1891, 66; Cameron, *For. Trees Mysore and Coorg*, 1894, 30–1; Morris, *Kew Bull.*, 1896, 204–7; also *Cantor Lect. in Soc. RYT RINA, Linn.; Fl. Br. Ind., ii., 188–90; LEGUMINOSÆ.

A genus of trees with prickly branches, large pinnate 3-foliate stipellate non-glandular leaves and conspicuous racemes of papilionate flowers, the petals being very unequal so that the standard is much the largest. There are some seven or eight species indigenous to India and widely cultivated remote from their truly wild habitats. They are the CORAL TREES (or Mochi-wood trees of Madras), the *parijāta* of the Sanskrit, and their generic vernacular name is *mandar* or *madar*.

D.E.P.,
iii., 6 –70.

. In *ca. Lamk.*; a native of Bengal near the sea, cultivated elsewhere; is the *pālita-mandar*, *paringa*, etc., and may be recognised by its blackish prickles. Perhaps this is the species figured and described by Bontius (in Piso, *Ind. Utri. re Nat. et Med.*, 1658, 135) in 1629. . *lithosper a*, Blume, is a native of Burma, Java and the Philippine Islands. A favourite with some of the coffee planters. It has large broad leaves and is often almost devoid of prickles. . *suberosa*, Roxb., is a native of the more interior tracts. It is characterised by having a thick corky bark and is the *pāngrā* (or *pāngará*), *mandal*, *munri*, etc.

These and other species have from the most ancient times been employed in Indian agriculture as shade-trees and as supports for climbing plants. The belief is universal that they exercise a beneficial influence on the soil, though the explanation of this circumstance, like the employment of clover in Europe, remained inexplicable till the discovery had been made of the value of the root tubercles of these plants in harbouring nitrogen-feeding bacteria. The following crops may be mentioned as those specially noted in which these trees are used—*areca* palm (p. 84), *Coffea* (pp. 379, 383), Pepper-vine (p. 899), and Tea (p. 228). [Cf. *Agri. Journ. Ind.*, 1907, ii., pt. 1, 83.]

Coca.

Introduction into India.—The Coca plant was introduced into Ceylon from Kew in 1870. At a committee meeting of the Agri.-Horticultural Society of Madras in May, 1876, a letter was read from Mr. Joseph Stevenson in which he suggested the propagation of the plant, in view of the probability of its becoming an important article of commerce. No steps, however, were taken till 1885,

when, owing to the discovery of the value of cocaine as an anæsthetic, the demand in Europe for the Coca leaf was rapidly increased. About then the Agri.-Horticultural Society of India distributed young plants from their Calcutta Gardens to the various tea-growing districts, and in the same year the Government of India addressed the Secretary of State for India, with a view to ascertain the method of preparation of the leaf as pursued in South America.

Cultivation.—Various attempts have, however, been made to grow *E. Coca* in India. Those in the Sikkim (Cinchona plantations) were a failure, but on the slopes of the Nilgiris and other parts of the Madras Presidency the plants have thriven much better. The slightest degree of frost appears to be fatal, and for this reason cultivation on the higher Himalaya has been abandoned, but at lower altitudes, from about 100 to 2,000 feet above sea-level, more encouraging results have been obtained. It is said that in Assam and Sylhet the plant has been grown satisfactorily. But it is affirmed that several species, besides the one here specially indicated, are employed as sources of cocaine, in addition to not a few well-recognised varieties of the true cocaine plant. From the leaves the crystallisable drug is obtained. Some of the species contain a large quantity of the drug not in a crystallisable form, and in consequence are comparatively valueless. It is, therefore, essential to obtain the correct plant, and to know whether the climate and soil of a proposed new plantation favour the formation of crystallisable cocaine. It is usually affirmed that for that purpose a rich and light soil is required. In other words, the plant is grown most successfully on well-drained moist loams, rich in humus; but as it exhausts the land, manuring is necessary after heavy cropping. There are said to be two chief varieties, one with small, the other with large leaves. These may be raised from cuttings, but if cultivated to any extent, seedlings should be produced in nurseries and the young plants put out into the fields when from 8 to 10 inches high. A writer in the *Journal of the Agri.-Horticultural Society of India* urges the necessity of a liberal supply of water to aid in germination. High rainfall is essential for the growth of the plant. In the Andes the only climatic variation is in degrees of humidity, and it rains more or less every month. The first harvest may be expected eighteen months after the time of planting, and once successfully established, the shrubs yield for forty years.

The leaves are ready for gathering when they become rigid and break on bending. Two, three or even four crops may be obtained in one year from strong plants in rich soil. The leaves are picked singly, but care must be taken not to pluck leaves nor shoot too young. A dry day should be chosen for harvesting and the picking should not be carried beyond noon, so that the leaves may be exposed several hours in the sun to dry. In India various methods of artificial drying in tea-driers or charcoal *chulas* have been experimentally tried. The dried leaves should be put aside for a day or two, and then packed. The best method of packing coca is to seal it up as soon as it is perfectly dry, in airtight packages, similar to those used for tea. Shipping should take place as soon as possible, for the leaves keep in good condition a much longer time in temperate climates than in the tropics. No commercial attempt has as yet been made to separate the alkaloid and its salts in India, though reports have appeared of the results obtained in the laboratory with Indian leaf. Hooper (*Rept. Labor. Ind. Mus. (Indust. Sec.)*, 1900-1, 20-1), records, for example, the results of his examination of samples from Assam and the Wynaad. It was found that the leaves rapidly deteriorate if kept for any length of time, more especially if imperfectly packed.

The leaves have the property when masticated of communicating a remarkable sustaining power, due to their containing cocaine. On this account they are chewed by the Peruvian Indian, and are to him what *betel pan* is to the Hindu, *kava* to the South Sea Islander, and tobacco to the rest of mankind. Both the alkaloid and its salts are stimulant and restorative. Injected hypodermically or painted externally, they produce local anæsthesia, and are much used in minor operations, particularly in ophthalmic and dental surgery. Its employment in this form was first recommended by Dr. C. Koller of Vienna in 1884, though the anæsthetic action was known twenty years previously. [*Cf. Kew Bull.*, 1889, 1-13; 1894, 151-3; *Pharmacog. Ind.*, 1893, iii, 131-4, app.; Garsed, *Brit. and Colon. Druggist*, 1901, xl., 413; Lenton, *Pharmaceut. Journ.*, 1903, lxx., 390-1, 420-1; Garsed, *Pharmaceut. Journ.*, 1903, lxxi., 784-91; Hooper, *Coca and Cocaine Habit, Lecture in "Statesman,"* Feb. 19, 1904; Pickett, *Veg. Alkaloids*, 1904, 232-7; White and Humphrey, *Pharmacop.*, 1904, 136-40.]

Trade and Cocaine Legislation.—The records of the traffic in the drug are very meagre. The world's supply comes chiefly from South America, but recently Ceylon has begun to export a small amount. India is thus mainly interested in the import traffic, and the repressive measures of the Government. The quantity imported was returned in the official statistics for the first time in 1903, when it amounted to 1,400 oz., valued at Rs. 18,442. In 1904-5 it was 5,431 oz. (Rs. 59,916), and in 1906-7, 1,771 oz. (Rs. 19,999). Hooper has published a graphic sketch of the growth of the Indian habit of cocaine indulgence. This has also been fully discussed by Dr. K. C. Bose and other writers (*Ind. Med. Gaz.*, Oct. 1901; March 1903). The Bengal habit seems to have originated in Bhagalpur, and spread to Calcutta. Shortly after it was carried to Bombay and Rangoon. So rapidly and alarmingly was this new vice being taken up that the Government of Bengal, with most praiseworthy zeal, in which it was also followed by the other Governments and Administrations, adopted repressive measures. In a notification of October 24, 1900, cocaine was included in the definition of "intoxicating drugs." In February 1902 the sale of the drug without a license became illegal. A further enactment of December 1, 1903, limited the amount that could be held or sold at one time. In consequence importations that would have exceeded the limits of possession were seized by the Customs authorities, and returned to the countries from whence procured. It can thus be affirmed that a wholesome check has been given which it is hoped may in time completely repress this most pernicious utilisation of an otherwise valuable medicinal agent.

Bastard
andal.

The wood is said to yield an OIL, used as a preservative for Native boats. It resembles tar, and is known in Ceylon under the name of *drummele*. It is extracted by packing pieces of the wood in an earthen pot inverted over a similar pot which is surrounded by fire.

Oil.

As a MEDICINE, Moodeen Sheriff (*Mat. Med. Mad.*, 73) describes the plant as possessing stomachic, diaphoretic and stimulant diuretic properties. In several parts of India the leaves and fruits are used as food in times of famine; in fact they might almost be said to be regularly eaten as a green vegetable. It is reported (*Ind. For.*, 1900, xxvi., 619) that during a recent famine in the Mysore Province the leaves had been largely eaten by the poorer classes. The time for gathering varies from June to December. They are boiled and mixed with salt and chillies. Dr. Bidie suggested that "probably the leaves contain some principle like that of *E. Coca*," but specimens analysed by the Government Quinologist in Madras were proved to have no anæsthetic property, but to possess a bitter tonic principle which might serve to mitigate the pangs of hunger. [*Cf. Cameron, For. Trees. Mysore and Coorg*, 1894, 44; Biscoe, *Hyderabad Trees*, 1895, 6; *Ind. Pharmacol.*, 1896, 55.]

Famine Food.

UG NIA, *Linn.* This genus of MYRTACEÆ embraces over 700 species, 120 of which are trees met with fairly plentifully in India. A few (such as the Clove, the Rose-apple and the Jaman-plum) are of considerable importance. Most modern botanical writers break up that vast assemblage of plants into three genera (or sub-genera) under the names *Jambosa*, *Zyzygium* and *Eueugenia*. The less important Indian species may be disposed of at once and the major portion of the available space devoted to the clove, which although not a native of India, is nevertheless traded in all over the country so universally as to make it one of the most important of spices, and one which the future may see produced very much more largely by Indian planters.

Jaman
Plum.

. (*zygium*) J bolan , *Lam.*; *Fl. Br. Ind.*, ii., 499; the Black plum, Jaman-plum, *jambu*, *jaman*, *jam*, *jambul*, *kuda*, *naval*, *nerale*, *zebri*, *thabybyu*, etc., and *perin-njara*, according to Rheede (*Hort. Mal.*, 1676, v., t. 29).

A small evergreen tree met with throughout India and Burma, ascending the hills to about 6,000 feet. Is chiefly found along river-beds and is specially cultivated for its FRUIT in gardens (*topes*) and in avenues. There are several varieties that yield much better flavoured fruit than others, but as a rule it is astringent, and only serviceable when cooked in tarts and puddings. In Goa a wine is prepared from it, and a spirit (*jambava*) is spoken of, by recent Sanskrit authors, as distilled from the *jambu*. Some years ago brandy was made at Monghyr from the fermented fruit. The *jaman* is extensively used all over India in the manufacture of vinegar (see pp. 1109-10). Recently attention has been directed to the SEEDS as a cure for *Diabetes Mellitus* (Christy, *New. Comm. Pl.*, 1893, No. 8, 77; *Pharmacog. Ind.*, ii., 25-9). The *tasar* SILKWORM is said to feed on the leaves of the tree. The TIMBER is fairly durable and is largely employed for building purposes, for agricultural implements and for well-work, since it resists the action of water. It gives a good fuel. The *jambu* is one of the trees held in veneration by the Buddhists (Monier Williams, *Buddhism*, 576), and is often planted near Hindu temples because regarded as sacred to Krishna. [*Cf. Baber, Memoirs*, 325; Garcia de Orta, *Coll.*, xxviii.; Linschoten, *Voy. E. Ind.* (ed. Hakl. Soc.), ii., 29; Taleef Shereef (Playfair, transl.), 65; Buchanan-Hamilton (*Stat. Acc. Rose-apple.

. (J bos) J bos, *Linn.*; *Fl. Br. Ind.*, ii., 474. A small tree cultivated here and there throughout India, and probably wild in Eastern Bengal and Assam. The Rose-apple, *gulab-jaman* (i.e. rose-jaman) and *nati-schambu*, according to Rheede (*Hort. Mal.*, i., t. 18).

This fruit is met with throughout Northern and Eastern Bengal, Assam, Manipur, and the Naga hills, and has in these countries all the appearance of having been long acclimatised, if not indigenous. The FRUIT is produced during the rainy season, and is about the size of a small apple. By many persons it is highly esteemed on account of its delicate flavour, but is not juicy enough to be a universal favourite. The tree is very ornamental, and is often seen in gardens even where the fruit is not appreciated. [*Cf. Boym, Fl. Sin.*, 1656, pl. F.; Buchanan-Hamilton, *l.c.* 196; Robinson, *Disc. Acc. Assam.*, 1841, 43.]

European
Names.

istory.—The name Clove denotes its resemblance to a nail (*clavus*), hence *clavo* (Sp.), *clou* (Fr.), *nelken* (Germ.), and *mekhak* (Pers.). In later Sanskrit it

is *lavanga*. Mr. F. W. Thomas (whom I have had the pleasure of consulting on this subject) tells me that the earliest occurrence of the name is in the *Ramayana*; Charaka is the first medical writer who alludes to the clove. But the word *lavanga* has passed into most of the more recent languages of India, and become *lawanga*, *lavinga*, *labang*, *laung*, *langa*, *lóng*, *raung*, etc., thus showing a common source. Mr. Thomas, commenting on the possibility of *lavanga* being a Sanskrit word, says, "I should think that the chance of its being Malay is the greatest. It has a Malay appearance. . . . In Malay *bunga lavang* is the term used, *bunga* meaning gay or variegated, especially a flower. *Lavang* by itself seems to be used for 'mace.'" [Cf. Reinwardt, *Reis in den Indischen Archipel.*, 1838, 465; Uhlenbeck, *Sanskrit Etymology*; *Encyclop. van Nederlandsche Indie.*] But, in addition, the clove bears in South India the names *kirámbu*, *karampu*, etc., words which Dymock (*Mat. Med. W. Ind.*, 1885, 328) suggests may have been the source of the *caryophyllon*. But it is probably more safe to assume that these South Indian names were derived from the Greek, through the Arabic *karanfal*. The Tamil name for *Cinnamomum zeylanicum* is *lavanga*, and Crawford (*Dict. Ind. Islands*, 1856, 215) gives that as the Borneo name for the clove-bark—a species of Cinnamon. In another passage (101-2) Crawford observes that *lawang* is a name used by the Malays for the clove, but brought to their country by the traders from India. Another name for the clove (in the Malaya), he says, is *gaumedi*, a word which Prof. Wilson, it would seem, translated "Cow's marrow" and regarded as of Sanskrit origin.

Earliest Record
in India.

Sanskrit Names.

South Indian
Names.

The Clove thus bears no undoubted Indian aboriginal names, and was probably not known in India much before the 5th century. The clove is not mentioned in the *Periplus* (63 A.D.) among commodities carried from India. There would seem, moreover, no doubt that it is the *caryophyllon* of Paulus Ægineta (Adams, transl., 1847, 160)—a Greek physician who wrote about the clove of the 6th century A.D., and who speaks of the spice in such terms as to imply that it was well known. Passing over several centuries, it may be observed that Caspar Bauhin (*Pinar. Theat. Bot.*, 1623, 410) was correct when he pointed out that Serapion was in error citing Galen. The account of the *garioflus* given by Serapion (9th century), Avicenna (10th century), and by other Arabs is literally transcribed from Paulus.

It is a well-established fact that the Chinese traded with Amboyna and India at a time anterior to any definite knowledge of these countries being possessed by the inhabitants of Europe. The Arabs also had a direct commerce of their own with India and the Malay Islands. In consequence various commodities came to be known to the Indians, Egyptians, Greeks, etc., at earlier dates than might be otherwise easily accounted for, and moreover were sometimes spoken of as Chinese, Indian, Ethiopian, Arabian, etc., in consequence of the nationality of the traders, rather than the countries of supply. Hence very possibly the statement of Paulus Ægineta (and of most of the early writers) that cloves "were brought from India." As a matter of fact the clove even down to the present day can hardly be said to be systematically cultivated anywhere in India. Marco Polo (*Travels*, 1290 (ed. Yule), ii., 217) speaks of the cloves of Java, but his observation must be interpreted to denote the extensive traffic that even in his time had been established, since the clove did not then grow in that island. Barbosa (*Coasts E. Africa and Malabar* (ed. Hakl. Soc.), 184, 219-20) visited Malabar and the "spice isles," and wrote, "The clove grows in the islands called Molucche, and from these it is brought to Malacca and thence to Calicut, a country of Malabar." So again, speaking of Pegu, he remarks there is much trade in cloves and mace and other Chinese goods. Varthéma (*Travels*, 1510 (ed. Hakl. Soc.), 245) also visited the Moluccas and gives a detailed description of the clove. Pigafetta investigated the clove plantations of Molucca in 1512, and wrote a full account of the methods of cultivation and manufacture of the spice. Garcia de Orta, who was in India from about 1535, and published at Goa in 1563 his *Colloquios dos Simples*, etc., says (*Coll.*, xxv.) that the possession of the Molucca Islands (and thus of the clove and nutmeg trade) was the cause of the war between the Spanish and the Portuguese. But it would be absurd to believe that cloves were not known prior to the discovery of the Moluccas. The price of cloves is stated in the *Ain-i-Akhbari*, a work written in Agra (1590), so that they were by then regularly known and traded in all over India (Blochmann, transl., 64). Linschoten gives an exhaustive account of the spice about the same date, and Pyrard (1601) also described it. In 1603 the

cloves

Company were trading in cloves (Birdwood and Foster, *E.I.C. First Letter Book*, 36), and a little later we read of the cultivation being rapidly extended all over the tropics. Rheedee does not, however, apparently describe the plant, so that very possibly it was not being cultivated in India during 1686—the date of his great work—the *Hortus Malabaricus*. About that time, however, the spice was an important article of trade with India. Tavernier (*Travels Ind.*, 1676 (ed. Ball), ii., 17), for example, discusses the Dutch monopoly and the clove traffic of Surat. [*Cf. Acosta, Tract. de las Drogas*, 1578, 30-4; Thevenot, *Travels in Levant, Indostan, etc.*, 1687, pt. iii., 109.]

Amboyna
Names.

Rumphius figures and describes the clove plant (*Herb. Amb.*, 1750, ii., 1-5, t. 1), and gives a long list of its vernacular names. He lived and died in Amboyna and was, in all probability, familiar with every aspect of the clove plant and trade. The Chinese, he says, called it *thenghio* (= sweet-smelling nails); the modern Malay name is *tsjanke* and the old Malay name *bugulawan*; in Amboyna it is *buhulawan*; in Ternate *bohulawa*, and in Tidora *gomode*. Filet (*Plantkundig Wordenboek*) gives it the name *bobolawa*. Crawford (l.c. 101) says, "It is very difficult to understand how the clove could have come first to be used as a condiment by foreign nations, considering the well-ascertained fact that it has never been used as such, and indeed hardly in any other way, by the inhabitants of the countries which produce it." He then proceeds to explain that the earliest names in the Moluccas for the clove are connected with the foreigners who came to their shores to procure the spice. The most frequent name, he says, is *cangkek*, which has not the sound of a native word, but is a corruption of the Chinese *theng-hia*. There seems no doubt the Chinese procured the clove from its island home for several centuries before it had reached Europe. There are records that point to this traffic as early as 260 B.C. Crawford, however, mentions none of the names given by Rumphius, but if these be actually the local names of the tree they have not apparently accompanied the clove into the commerce of the world. Little astonishment need, however, be expressed at these names not having accompanied the clove, when it is recollected that it was not regarded by the inhabitants of the "spice islands" as of any value until the Chinese desired to be supplied with the "little sweet-scented nails." In that circumstance alone lay the interest taken by the people of Moluccas in the plant, and "nail" or "clove" became its name in most countries.

Chinese Names.

Migration.

Sonnerat (*Voy. Nouv. Guin.*, 1776, 195, tt. 119-20) tells us that he found the clove being grown in New Guinea, and it is well known that in 1770 M. Poivre, of the Isle of Bourbon, sent M. Prevost to Ceram in order to procure live plants of both the clove and the nutmeg. This enterprise was completely successful, and shortly after the plants flourished so well in their new home that seedlings were sent to Cayenne about 1784, and in an incredibly short time the plantations were extended and cloves regularly sent into market of such quality that they were pronounced equal, if not superior to those of the "spice islands." Very shortly after the date mentioned the clove was carried to the West Indies (Dominica in 1789), in fact throughout the tropical world, and was even cultivated by Sir Joseph Banks at Kew in 1797. It had been successfully acclimatised in Zanzibar and Pemba. Migration became imperative, through the short-sighted policy of the Dutch, who sought to secure for themselves an absolute monopoly in the world's supply. For this purpose they ruthlessly destroyed the trees in all the islands except those specially set apart by themselves for clove-production. Having trampled on the rights of the people, retribution became a natural consequence. It is not much to be wondered at, therefore, that when in time a more liberal policy prevailed, the new countries of clove-production had so securely established their positions that a restoration or concentration of the traffic in the original home of the clove became an impossibility.

Retribution.

Cultiva-
tion.
Bud.

Cultivation.—Cloves are the dried unexpanded flower-buds of this tree. The corolla forms a ball on the top between the four teeth of the calyx, and the stalk is the immature ovary. They are at first green, then turn yellow, and finally bright pink or scarlet. In this last stage they are ready to be picked. If allowed to remain longer on the tree the flowers expand, become fertilised, and the stalk of the clove then develops into a succulent purple-coloured berry containing one or two seeds. This is known technically as the "mother clove." These are sown in

"Mother Clove."

rich mould about 12 inches apart, and the fresher the better, since the seed when dried soon loses its vitality. They germinate within five weeks and when 4 feet high are transplanted from the nursery into their final positions, 20 to 30 feet apart. The soil must be porous, well-drained, and consist of mould with a fair proportion of sand. The plants will not thrive on clay nor pure sand, and marshy land is fatal. Even in the Malaya the clove tree does not luxuriate alike on all the localities on which grown, and seems to prefer a soil formed from volcanic rock (Crawford, *l.c.* 101). In Pemba the soil most suited is a dark loam, having underneath a layer of dusky yellow earth intermixed with gravel, also a yellowish or reddish stiff clay (*Kew Bull.*, 1893, 17-20). Although indigenous to islands it does not succeed well when exposed to the direct sea-breezes. It prefers confined valleys, though dense overhead shade is highly injurious. Protection from high winds is essential, and a tree hedge along the windward side of the plantation is very desirable. But in place of seed the plant may be raised by layering. Young branches laid across the ground take root in about six weeks. The young plants should be transplanted at the beginning of the rains. Shade is necessary for the first two or three years, and watering occasionally is advantageous during exceptionally dry weather, both before and after transplanting. By the end of the third year the shade should be removed, and by the sixth the plants will have come into bearing and be in full crop by the twelfth. By 20 to 25 years they are usually too old to be profitable, though they may yield up to 150 years. It is accordingly customary to renovate certain portions of the estate every 8 years. In the Moluccas the trees are topped at 8 or 9 feet, so as to secure low plants easy of being picked. Each tree should give about 6 to 7 lb. of dry cloves. The best course is to hand-pick the clusters of buds, but occasionally they are beaten off the trees and caught on cloths spread below, or the ground is swept clean, so as to allow of the cloves being picked up without being injured. Every third or sixth year a heavy crop is obtained, and now and again (especially if over-cropped or injured) the trees bear next to no flowers.

In the spice islands the cloves are sometimes cured by being smoked over a shallow wood fire, until they assume a deep brown colour, when the further drying is accomplished by the sun. Occasionally the buds are scalded in hot water before being dried. But if bright sunny days prevail artificial heat may be dispensed with and the buds sun-dried from first to last. The crop loses about 60 per cent. in drying.

Nicholls (*Textbook Trop. Agri.*, 1892, 184-9) gives useful particulars of clove cultivation. A most interesting and instructive account of the production, manufacture and trade in this spice was also written by Mr. J. C. Sawyer in *The Produce World* (May 1896). Mr. R. N. Lyne of Dunga, Zanzibar, published a valuable report on the plantations of that island, now by far the most important single country of production. [*Cf. Trop. Agrist.*, July 1901, 11-2; *Der Tropenpflanzer*; *Journ. Soc. Chem. Indust.*; *Pharmaceut. Journ.*; *Chem. and Drugg.*; *Dipl. and Cons. Repts.*; etc.]

Uses.—It is needless to say that the clove, though not held in such high esteem as in former times, is still a spice of considerable commercial importance. OIL OF CLOVES will be found dealt with in great detail by Gildemeister and Hoffmann (*Volatile Oils*, 1900, 512-8). It would appear that it was first distilled in the 15th century. The cloves of Pemba are those chiefly used for this purpose. Those of Amboyna and

Oil.

ansá sij

INDIAN SPURGEWORTS

Reunion are richer in oil, but command, as a spice, too high a price to be used in distillation. The most expensive clove is that of St. Marie in Madagascar. Clove-oil is largely employed in perfumery. Its value is estimated by its *eugenol* content, which varies from 76 to 85 per cent.

Trade.

Exports.

Imports.

Trade.—Zanzibar and Pemba yield four-fifths of the total clove-supply of the world. There is a small *EXPORT* of Indian-grown cloves from Madras, a circumstance that points to a certain amount of cultivation. The traffic is, moreover, an expanding one. In 1899–1900 these exports stood at 148 lb.; in 1901–2 at 3,329 lb.; in 1903–4 at 12,598 lb.; in 1904–5 at 25,537 lb.; in 1905–6 at 11,825 lb.; and in 1906–7 at 5,173 lb. As compared with these records, the *IMPORTS* were 7,815,486 lb., valued at Rs. 17,63,050, in 1899–1900; 6,983,582 lb., valued at Rs. 15,33,174, in 1901–2; 6,659,913 lb., valued at Rs. 17,03,296, in 1903–4; 8,345,521 lb., valued at Rs. 22,01,424, in 1905–6; and 5,062,782 lb., valued at Rs. 16,28,355, in 1906–7. Practically the whole comes from British East Africa, and is received by the town of Bombay. There is an increasing trade from Germany (? Colonies), which supplied 1,100,068 lb. in 1905–6 and 798,851 lb. in 1906–7. The traffic with the Straits Settlements and China is insignificant—under 100,000 lb. from each taken by India. From the imports, however, are drawn the re-exports, viz. 1,000,000 lb., the major portion going to the Straits Settlements and China (Hongkong). India is thus once more a large emporium for the cheaper grades of clove, but in the opposite direction to its ancient traffic.

UPHO IA, *Linn.*; *Fl. Br. Ind.*, v., 244–66; Gamble, *Man. Ind. Timbs.*, 590–1; Brandis, *Ind. Trees*, 557–8; Prain, *Beng. Plants*, ii., 923–5. **EUPHORBIAEÆ**. This is a genus of herbaceous plants mostly, though a few assume the condition of useful hedge bushes or even small trees. There are in India some 53 species; 7 or 8 only are of economic value.

The English generic name Spurgewort denotes their chief medicinal property, but their greatest potentiality lies in the utilisation of their milky sap as a source of gutta-percha. It will be seen from the brief specific review that follows that this subject has engaged spasmodic attention in India for the past century or more without any practical results having been obtained. Hooper (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1905–6, 28–9) gives the results of his examination of the latex of two species. They yielded large quantities of euphorbium and resin to boiling alcohol. Many of the species are valued as manures in the reclamation of waste lands.

Hedge Plants.

. antiquoru, *Linn.*—A small tree of the dry regions of India generally. Is often used as a hedge plant, and best known by the following names:—*vajri* in Sanskrit, and in the vernaculars—*nara sij* or *narsej*, *tekátá sij*, *tidhára*, *shidu*, *kalli*, *bonta kalli*, *tazaung*, *pyathat*, etc. Fryer (*New Acc. E. Ind. and Pers.*, 1672–81, 105) alludes to the *Euphorbia* hedges of the Deccan, which doubtless to some extent consisted of this species. In some parts of Eastern Bengal and Assam this tree is almost sacred, and is supposed to protect the gardens around which planted, and like *E. nerifolia*, *Linn.*, has the merit, so it is thought, of safeguarding the inhabitants against snake-bite. Both are, in fact, sacred to *Mansá*, the goddess of serpents.

. neriflo a, *Linn.*—A small tr wild on rocky situations in the Deccan, West Coast and Orissa, but often seen under cultivation, especially in Bengal. It is the *mansá sij*, *páta-sij*, *sehrund*, *thor*, *nivarung*, *mingut*, *kalli*, *yellikalli*, *shazaung*. It has a more or less cylindrical stem (the allied form *E. tigularia*, *Roxb.*, being four- or five-angled) with stipular thorns on numerous tubercles.

Medicine.

The MILKY JUICE of this as also the foregoing species is used medicinally all over India; it is purgative and rubefacient. Is a popular application to warts and other cutaneous affections. Internally the juice is ually administered along with other purgatives and aromatics. In the *Indian Forester* (1891, xvii., 350) Gleadow tells the results of some experiments he performed to extract the

POSSIBLE GUTTA-PERCHA

EXC CA IA
AGALLOC A
Blinding Tree

rubber contained in the present species. His samples were sent to Europe and reported on in such terms as to discourage further effort. Unfavourable Report.

pilulifera, Linn.—A small herb found throughout the hotter parts of India from the Panjáb southwards. Is the *dudhi*, *dudeli*, *burakeru*, *pusitua*, *gordon*, *nayeti*, etc. Used in the affections of children—bowel and lung complaints. A fluid extract has been employed in asthma and in dysentery (*Rept. Cent. Indig. Drug. Comm.*, i., 154).

oyleana, Boiss.—A large shrub common on dry rocky hillsides of the outer Himalaya from Kumaon westwards, and also in the Salt Range. It is a most conspicuous and characteristic plant in the tracts of country indicated. Its ascending fleshy branches (or stems) are five-angled and thorny. It is the *thor*, *shakar pitan*, *sali*, *chilla*, *chün*, *sura*, *tsui*, *suru*, *sihund*, etc. The milk contains a large amount of gutta-percha. When fresh it has a sweet odour and does not blister the fingers, but it is very injurious to the eyes and flavours anything handled even after the greatest care may have been taken to clean the fingers. Some few years ago a fairly extensive series of experiments were conducted with this milk, having in view its utilisation as a waterproofing material or as a paint for ships. The subject is alluded to because sufficient evidence was obtained to satisfy belief that (without contemplating the utilisation of the milk as a gutta-percha substitute or the establishment of factories beyond both the means and the capabilities of the inhabitants of the country where *E. Boyleana* is an abundant and at present useless plant) there might still be directions in which it might be possible to convert the limitless supply into a source of wealth. (See Gutta-percha, p. 627.)

Gutta-percha.

Possible
Utilisation.

Tirucalli, Linn.—The Milk-hedge or Milk-bush or *sehund*, *shir*, *shera*, *lanka sij*, *seju*, *neveli*, *nival*, *kadu-nevali*, *jemudu*, *thuvur*, *yela-gulla*, *tirucalli*, *sha-shoung*, etc. A small tree with round stems and smooth branches. It is generally believed to be a native of Africa, but has been for many years completely naturalised in India, especially in the drier tracts of Bengal, the Deccan, South India and Ceylon. Heyne (*Tracts, Hist. and Stat. Ind.*, 1814, 243) discusses fully the possibility of utilising the milk of this and other Euphorbias. Drs. Riddle, Cheek and Falconer devoted much time and attention to the self-same subject about 1850. It was observed that after boiling, the milk of this species becomes brittle, though whilst warm it is ductile and elastic. Giberne (*Ind. For.*, 1899, xxv., 84-5) has urged the desirability of the milk of this and other species of *Euphorbia* being put to some useful purpose. He found that nitric acid caused the separation of the rubber. Mixed with mud the milk is employed in North Arcot in the construction of the flat roofs of houses. It is, in Ganjam, said to be used to intoxicate and poison crows: for this purpose a little is mixed with boiled rice and given to these birds. The acrid juice is in India generally, well known as a purgative and counter-irritant (especially in the treatment of animals), and it is so very painful when applied to wounds or to the eye that cattle are fully aware of this fact and will not attempt to break down a hedge of it. (Consult the controversy regarding Angola (*Almeidina*) Rubber—*E. rhipsaloides* versus *Tirucalli*.)

It may be the *taggar* wood of Sylhet alluded to under *Aquilaria* (p. 74). A small evergreen tree of the coast and tidal forests of both sides of the Indian Peninsula, Burma, the Andaman Islands and Ceylon.

The wood contains a milky juice which hardens on exposure to the air into a black caoutchouc-like substance. The sap which exudes from the fresh-cut bark is very acrid, some say poisonous, hence the name Blinding Tree or *arbor excns* (Rumph., *Herb. Amb.*, ii., tt. 79-80). Hooper (*Yearbook of Pharmacy*, 1899, 468) gives an account of the chemistry of this latex, which he analysed with a view to ascertain'g its value as a rubber. The TIMBER is useful for general carpentry purposes and for match-making. [*Cf. Pharmacog. Ind.*, iii., 1893, 314-5; *Ind. For.*, 1897, xxiii., 150.]

FAGOPYRUM, Gaertn.; *Fl. Br. Ind.*, v., 54-5; **POLYGONACEÆ**.

.esculentum, Moench; Duthie and Fuller, *Field and Garden Crops*, 1893, pt. iii., 25, t. 83; *Rec. Bot. Surv. Ind.*, i., 33, 40, 219, 262; Woodrow, *Gard. in Ind.*, 1899, 430; Mukerji, *Handbook Ind. Agri.*, 1901, 56, 260. This is best known as Buckwheat or Brank, *phaphra*, *kotu*, *kultu*, *rajgir*, *doron*, *ugla*, *ogal*, *bares katu*, *bres*, *trumba* (*tramba*), etc. Extensively cultivated on the temperate Himalaya and lower hills of India, from Afghanistan and Kashmir to Darjeeling, Assam and Burma. There are many cultivated states, some grown for the grain, others as a vegetable, and these blend imperceptibly into the wild *F. cynosum*, Meissn.

Temperate.

F. tataricu. Gaertn.; Duthie and Fuller, *l.c.* 26-8, tt. 84, 96. This is the *kaspas*, *kala trumba* (black *trumba*), *chin*, *karmabres*, *ugla*, *kathu*, *trao rjas*, etc. It is usually known as Black Buckwheat, but as a rule *phaphra* denotes *F. esculentum* and *ugla*, *F. tataricum*. This form is cultivated throughout the higher temperate Himalaya, especially on the western extremity between altitudes of 9,000 and 15,000 feet. It is a taller, coarser plant than the other species, having longer grains (nuts, as they are sometimes called) of a black colour, and with the angles rounded off and keeled toward the top, instead of being sharp. There are many cultivated forms, one from Kangra having been treated as a distinct variety under the name *himalaica*.

Alpine.

Cultiva-
tion.

Seasons,
 Lower Hills.

On the lower Himalaya, between 4,000 and 10,000 feet, *F. esculentum* is grown, being sown in July and reaped in October. In the lower reaches of its mountainous area it is usually raised more as a vegetable than a grain. Indeed in Northern and Eastern Bengal, Assam and Burma (and even in the Deccan, the Central Provinces and Bihar) it is often met with (on the plains) as a catch or garden crop, where it is exclusively used as a vegetable or fodder. Of the mountains of Assam, Manipur and Burma, it might be said that a climatic depression exists which admits of plants being grown two or three thousand feet below their normal habitats. Hence in these regions the grain-yielding buckwheat becomes an important article of food at altitudes even below 5,000 feet. In the higher reaches of its area buckwheat often becomes exceedingly important, more especially *F. tataricum*, which, following the spring barley or wheat, is sown in July and gives a supplementary crop before the early snowfall puts a stop to agricultural operations. It is frequently utilised as a first crop on new clearances, and in the most alpine tracts sheltered portions of the grassy slopes are utilised in giving a catch crop one year and left fallow for several succeeding years. It may also be grown on soils too poor for wheat and barley. It seems to succeed fairly well on rocky soils containing a high percentage of granitic detritus, but not on clay. Lawrence (*Valley of Kashmir*, 1895, 338) informs us that buckwheat (both species) can be grown late on almost any soil, and that in the higher villages *F. tataricum* constitutes almost the only food-grain of the people. In the lower valleys, he adds, irrigation is sometimes given. Mukerji urges the claims of buckwheat as a catch crop; it yields a return in ten weeks after sowing; it can be grown on poor soils and is able to withstand a greater extreme in heat and cold than can be said of any other known crop.

Plains—a
 Vegetable.

Higher Reaches
 Grain Crop.

Catch Crop.

Chief Food-grain.

Bread.
 Spinach.

As a human food buckwheat does not hold a high place, since about 20 per cent. of the weight is lost in decortication. The nuts are husked and ground into flour, which is made into bread or eaten as porridge. The leaves and shoots are boiled as a spinach. For poultry and horses, however, the unhusked nuts are regarded as very superior, while the straw is more nutritious than that of cereal. *F. tataricum*, var. *himalaica*, is a better food than *F. esculentum*, as it is richer in oil and contains less indigestible fibre.

[Cf. Kew. Bull., 1893, 3; McHutchin, *Assess. Rept., Kashmir*, 1894, ii., 5-14; Barclay, *Agri. Ledg.*, 1895, No. 20, 366-7; Diack, *Settl. FERULA, Linn.; *Fl. Br. Ind.*, ii., 707-8; Aitchison, *Trans. Linn. Soc.* (2nd. ser.), iii., 67-9. A genus of umbelliferous herbs which contains some sixty species found in Europe, North Africa and Central Asia. They grow from perennial root stocks, and some attain annually a height of from 8 to 10 feet. They afford the various forms of Asafetida, Galbanum, Sambul, etc.

D. P.
iii., 32-39.
Asafetida.

History.—The *silphion* of the early Greek writers was an edible product derived very possibly from a species of *Ferula*, but was not *asafetida* as accepted in modern commerce. The *laser* (*laserpitium*) of later writers, on the other hand, was very possibly the medicinal drug of the present day. Though botanically quite distinct, the edible *silphion* is strongly suggestive of the edible *hing* of modern Indian commerce. [Cf. Oersted, *Silphium of the Ancients*, in *Journ. Bot.*, 1873, ii., n.s., 176-9.] Theophrastus (*Hist. Pl.*, vi., ch. 3 (ed. Scaliger), 1644, 598-9) speaks of two varieties, one coming from the stem, the other from the root. Dioscorides mentions two kinds, one obtained from Cyrene, the other from Asia. Strabo contrasts the Asiatic gum with that known in Europe. Plautus (220 B.C.) makes frequent mention of *laser*, and Galen, Aëtius, Oribasius and Paulus Aegineta all deal with its medicinal virtues. Celsus gives an interesting description, and Pliny bases his encomium on the account furnished by Dioscorides, but he lays special stress on the fact that *silphion* had disappeared and its place been taken by the much inferior *laser* of Persia. By Sanskrit medical authors the gum is *hingū* and the plant *jatuka*; by Arabic writers it is *asa* or *hiltut*, and by Persian *anguzan*. But so far as can be learned there is no classic mention of the distinction between *hing* and *hingra*. References to the medicinal uses of the drug (*hingū* or *hingū*) will be found in *The Bower Manuscript* (5th century A.D.) (Hoernle, transl., 1893-7, 81, 85, 86, 180, etc.).

Arab Writers.

Myrepsicus was apparently the first writer who combined the Arab name *asa* with the descriptive word *fetida*, a new name, he tells us, used by the Italians. Ibn Sina (Avicenna), a Muhammadan, who lived in the 10th century, mentions two kinds of *asa*, viz. *tyib* (good) and *muntin* (fetid), while Ali Istakhri, who also lived about the same time, states that the drug was produced in the desert between Seistan and Makran. The geographer Edrisi, who wrote about the middle of the 12th century, says that *asafetida* was collected largely in Western Afghanistan. It is perhaps significant that Marco Polo, who marched (1290) through a great portion of the country where certain grades of this drug are produced, should make no reference to it. Garcia de Orta (1563, *Coll.*, vii.; also Ball, *Comment., Proc. Roy. Ir. Acad.*, 1889-91, 393) mentions that it was reported to reach India from Khorasan through Hormuz, but was also grown in Gujarat, and from Dely, a land bordering on Khorasan and Chiman. Acosta (*Tract. de las Drogas*, 1578, 362) gives many interesting particulars of the drug imported into India. Jacobus Bontius (*Hist. Nat. et Med. Ind. Or.*, in Piso, *Ind. Utri. re Nat. et Med.*, 1658, 41) relates that the plant from which *asafetida* is produced grows in Persia, between the States of Lara and Gamaron. Mandelslo (*Travels*, 1638, in Olearius, *Hist. Muscovy, etc.*, 84) furnishes a similar account. Bontius also states that by the Javans and the Malays and other inhabitants of India it is called *hin*. Fryer (*New Acc. E. Ind. and Pers.*, 1675, 239) intimates that *asafetida* is gathered at a place called Descoon, and says it differs from the stuff the Indians call *hing*, which comes from the province of Carmania.

Accounts of
Indian
Travellers.

No satisfactory account of the plant yielding *asafetida* was given till 1712 (Kämpfer, *Amoen. Exot.*, 537 and pl.). Hove (*Tours in Gujarat, etc.*, 1855, 133), who visited Bombay in 1787, describes the cakes flavoured with *asafetida* that he was given to eat. He also says there are two kinds—*hing* and *hingra*. Milburn (*Or. Comm.*, 1813, i., 133) gives a description of the commercial drug of his day, and states that it had been in use nearly 1,000 years. But he was in error when he supposed this to be the true *asafetida* plant. Aitchison, who travelled in Eastern Persia, Baluchistan and Afghanistan (with the Afghan Boundary Delimitation Commission of 1884-5) elucidated this obscure subject very largely.

Asafetida
Biscuits.

Hing and
Hingra.

He found the word *kema* generic, the asafetida plant being *anguza-kema*, and *Ammoniacum kandal-kema*. [Cf. Stapf, *Kew Bull.*, 1907, 375-88.] Commenting on this view, the authors of the *Pharmacographia Indica* (ii., 143) observe, "It would appear then that the kind of asafetida called *tyib* by the Arabs and their followers is the drug of European commerce, the produce of *Ferula foetida*, Regel, and not that of *F. alliacea*, Boiss., which produces the *hing* of India." Holmes in the *Pharmaceutical Journal* (3rd ser., xix., 21-34, 41-4, 365-8), and the various Museum Catalogues of the Pharmaceutical Society of Great Britain, has afforded many useful particulars and focussed the practical results of recent research. A long account of the philology of the word "asafetida" is given by Prof. J. Attfield (*Yearbook of Pharmacy*, 1897, 351-6), who, after consulting Dr. Murray (editor of the *Oxford Dictionary*), had come to the conclusion that it should, both in English and Latin, be rendered "asafetida." When discussing the *hing* and *hingra*, it seems probable that it would be more correct to assign these to groups of species rather than to say that they were each the product of one species. Indeed it would appear that the part of the plant from whence procured, the season of the year when collected, the methods of preparation and degrees and materials of adulteration, exercise considerable influence on the quality and flavour of the resulting drugs. It is, however, convenient to group the commercial resinous products of *Ferula* under three chief species:—

F. ili ce, Boiss.; Bentley and Trimen, *Med. Pl.*, 1880, ii., 126; Dymock, *Mat. Med. W. Ind.*, 1885, 381. In Khorasan it is called *angushkeh*, in Kirman, *zendebuj*, while it is also known by the following names—*hing*, *anjudán*, *vagárni*, *abhushaharu hing*, *káyam*, *perun gayam*, *inguva*, *anguza*, etc. A herb which grows to a height of 2 to 4 feet. It is found wild (is not, at all events, cultivated) in Eastern Persia in the neighbourhood of Djendack and Yezd, and in Khorasan near Seharud, Nischapur, Meshed, Dehrachtindjan and Kerman. It prefers a stony, arid soil, and is found at an altitude of 7,000 feet. This plant is the chief source of the asafetida used in India and known as *hing* (which means pure or superior *hingra*), while that of European commerce is the product mostly of *F. foetida*—*hingra*.

Gum-resin.
Hing.

This might be spoken of as the edible form. The GUM-RESIN is obtained by wounding the upper part of the root, from which a small quantity of a fine gum escapes and is collected. The living root is then sliced daily, or every two or three days, with the exudation adhering to it, till exhausted. The whole mass, consisting of alternate layers of root and gum-resin, is then packed in a skin. As found in the market, the resin consists of a blackish-brown, brittle mass of extremely fetid odour, unadulterated with earth or gypsum, but always with slices of the root. In Bombay it is sometimes adulterated by the addition of gum-arabic, and the cheaper sorts contain an undue proportion of root. Adulteration with sliced potato also takes place.

Chemistry and
Medicine.

The resinous mass contains an abundant essential oil which differs from that of *hingra* in having a reddish hue, a higher specific gravity, and a stronger rotatory power. An alcoholic tincture is not precipitated by acetate of lead, nor is the sulphuric-acid solution fluorescent. From earliest times the gum has been held in esteem by Eastern doctors. It is a carminative and antispasmodic, and taken daily is said to ward off malarial fever. It is also recommended as a vermifuge. [Cf. *Pharmacog. Ind.*, 1890, ii., 141-7; Kanny Lall Dey, *Indig. Drugs Ind.*, 1896, 127-8; Thorpe, *Dict. Appl. Chem.*, 1898, ii., 273.]

F. f tid, Regel; Drude, in Engler and Prantl, *Pflanzenfam.*, iii., 231; *Kew Mus. Guide*, 1907, No. 1, 115; *hingra*, *anguza-kema*, *kurne-kema*, *khora-kema*, *vaghayani*, *hingu*, etc. A herb with a circular mass of foliage, springing annually from a perennial root stock. It grows in Southern Turkestan, Persia and Afghanistan. This would appear to have been the Persian plant sent by Dr. Guthrie of Edinburgh, and grown in the Botanic Gardens there in 1780. [Cf. *Phil. Trans.*, 1785, lxxv., 36.]

Gum-resin.—This is the European drug of commerce, and is obtained from Laristan in Persia and from Herat in Afghanistan. It is collected in June,

the method pursued being briefly as follows:—The tap-roots are exposed for a couple of inches. A thick slice is cut from the top, from which a quantity of milk exudes. The root is then protected from the sun by a domed structure, 6 to 8 inches in height, called a *khora*, formed of twigs and clay and which has an opening towards the north. In five or six weeks' time a thick, gummy, reddish substance appears in irregular lumps on the exposed substance of the root. This is scraped off or removed along with a slice of the root, and placed in a leather bag. It was reported that the plants were sometimes operated upon more than once during the season. The gum is next carried to Herat, where it is deliberately adulterated. [Cf. Aitchison, *Pharm. Journ. and Trans.*, Dec. 11, 1886.] Masson (*Journ. Kalat*, 1848, 451-3) speaks of the plant as flourishing in Seistan, the gum being collected as *nushki*. Bellew, in his account, says that after cutting the plant through, above the root, three or four incisions are made in the stump, and the operation of incision is repeated every three or four days, so long as sap continues to exude. A particular sort is mentioned by the same writer as being obtained solely from the node or leaf-bud in the centre of the newly sprouting plant. This kind is never adulterated, and may be the fine quality of the drug known as *Khandahari-hing* (*Pharmacog. Ind.*, ii., 151). The common form is much adulterated by a kind of red clay (*tawah*), by wheat or barley flour, and by powdered gypsum. It is also mixed with slices of the root. All species of the drug have a powerful, garlic odour, and a bitter acrid taste. Except *Khandahari-hing*, this variety of *asafetida* is not used in India.

Adulteration.

Maynard and Prain, on the Botany of Baluch-Afghan Boundary Commission of 1896 (*Rec. Bot. Surv. Ind.*, i., 130-1), furnish interesting details of the collections of the commercial article on the hills between Samuli and Robat. *Asafetida*, they observe, affects bare rocky hillsides. It is the plant, or at least one of the plants, that people from Kandahar yearly visit the Koh-i-Sultan to collect. Sir Arthur H. McMahon described the collection of the gum from personal observation. The heads are cut down to within one or two inches of the ground. The cut ends are then covered with a little dry earth in order, the collectors say, to keep the wind off. After twenty hours the people collect what has exuded and cut the stalk down another eighth of an inch. But the milk is not allowed to dry in the sun; to obviate this the collectors build small stone traps, open at one side, over each plant, in order to keep off the sun's rays. The juice when partly dried is mixed with some kind of earth, like fuller's-earth; this is merely to increase the weight, and not with any idea of improving the quality. Doubtless the precautions taken to prevent drying are mainly with a view to facilitate this subsequent adulteration.

Method of
Collection.

Asafetida consists of resin, gum and essential oil in varying proportions, but the resin generally amounts to more than one-half. It is partly soluble in ether or chloroform. The oil may be separated by distillation. It is light-yellow, with a pungent odour, and if exposed to the air evolves sulphuretted hydrogen. An alcoholic tincture of the drug is precipitated by acetate of lead, and a solution in sulphuric acid is fluorescent. Medicinally it is used in Europe as an antispasmodic and stimulant (see *Vinegar*, p. 1110).

ed icine.

According to Bellew, Masson and Aitchison, the Natives of Bokhara employ the leaves as a green vegetable, while the white underpart of the stem of the full-grown plant is considered a delicacy when roasted and flavoured with salt and butter. [Cf. Borszczow, *Ferulaceen*, 1860, 3-26; *Pharmacog. Ind.*, 1890, ii., 147-52; *Gard. Chron.*, 1896, 330-1; Thorpe, *Dict. Appl. Chem.*, 1898, ii., 273; Dutt, *Mat. Med. Hind.*, 1900, 175-6; White and Humphrey, *Pharmacop.*, 1904, 82-3; Tschirch, *Die Harze und die Harzbehälter*, 1906, i., 360-76.]

F. lb i, *Boiss. & Buhse*.—This is the chief source of the drug known as Galbanum; *bireja*, *ganda-biroza*, *badra-kéma*, *barzed*. It is a native of Persia (especially Shiraz and Kirman), from which the gum is imported into Bombay and re-exported to Egypt and Turkey. Around Gulran it is reported to be specially common.

Gum-resin.—There are three kinds known in commerce: Levant, Persian, Solid, and Persian Liquid. The first comes from Shiraz, and is known as *khassmib*; the second has an odour of turpentine, and the third is the *gao-shir* or *jawdshir*. As met with in India, *gao* (*jao*)-*shir* is a yellow or greenish semi-fluid resin, generally mixed with the stems, flowers and fruits of the plant. It is obtained from the

stem, which, when injured, yields an orange-yellow gummy fluid. Generally, however, the galbanum of commerce forms round, agglutinated tears, about the size of peas, orange-brown outside, yellowish-white or bluish-green inside. The odour is not disagreeable like that of asafetida, and the taste is bitter.

Medicine.

Galbanum consists essentially of about 65 per cent. resin, 20 per cent. gum, 3 to 7 per cent. volatile oil. The oil is obtained by distillation with water or by extraction with petroleum ether. In medicine, galbanum is administered internally as an expectorant, and externally it enters into the composition of plasters. [Cf. Cooke, *Rept. Gums, Resins, etc., in Ind.*, 1874, 60-1; Bentley and Trimen, *Med. Pl.*, 1880, ii., 128; *Pharmacog. Ind.*, ii., 152-6; Thorpe, *Dict. Appl. Chem.*, 1898, ii., 274; Schimmel & Co., *Semi-Ann. Rept. April-May*, 1901, 36; *Chem. and Drugg.*, 1901, lix., 374-5; Tschirch, *l.c.* 346-58.]

F. N rthex, Boiss.; *Narthea asafetida*, Falconer, *Trans. Linn. Soc.*, 1846, xx., pt. i., 285-91; Balfour, *Trans. Roy. Soc. Edinb.*, xxii., pt. ii., 261-8, pl. 20-1. This plant owes its discovery to Falconer, who found it in 1838 in Western Tibet on the slopes of the mountains dividing that country from Kashmir. From the plants thus collected seeds were sent to the Edinburgh Botanic Gardens and thence distributed all over Europe.

Holmes mentions that in a letter Aitchison reports that he had come on *F. Narthea* at the very locality where he believed Falconer originally found it. He also says that Sir W. R. Lawrence, during his official tour through Jammu and Kashmir in 1893, saw the plant in flower between Astor and twenty miles north, near Doian. This plant was at one time accredited as the source of Tibetan asafetida, but as already mentioned the European drug comes from Persia and may be accepted as the produce of *F. foetida* and the Indian of *F. alliacea*. [Cf. *Rec. Bot. Surv. Ind.*, i., 40; Holmes, *l.c.* Aug. 1894, 131; *Kew Bull.*, March 1895, 57; *Chem. and Drugg.*, 1901, lix., 374-5.]

Imports.

Trade in Asafetida.—The following figures are returned as the Trans-frontier imports of asafetida into British India from Afghanistan, Seistan, etc., for the years 1902-7:—1902-3, 1,368 cwt., Rs. 1,73,760; 1903-4, 2,055 cwt., Rs. 2,63,891; 1904-5, 2,036 cwt., Rs. 2,58,762; 1905-6, 1,106 cwt., Rs. 1,38,901; 1906-7, 1,820 cwt., Rs. 1,59,873. During the years 1903-4 the IMPORTS by sea were 13,343 cwt., valued at Rs. 4,89,538; and in 1906-7, 6,062 cwt., valued at Rs. 2,42,635. Practically the whole of the foreign imports came from Persia and went to Bombay.

Exports.

THE EXPORTS are returned both as foreign re-exports and as Indian produce. The latter of course means asafetida brought to India by land routes. Of the foreign produce, 1,612 cwt. were exported in 1903-4, valued at Rs. 53,440; and 1,250 cwt., valued at Rs. 39,758, in 1906-7. Practically the whole went from Bombay. Of the so-called Indian produce, 332 cwt., valued at Rs. 13,548, were exported in 1903-4, but sank to 51 cwt., valued at Rs. 2,043, in 1906-7. The export figures should, however, be regarded as having reference to *hingra*, while the returns of imports are both *hingra* and *hing*. [Cf. *Brit. and Colon. Drugg.*, 1905, xlvii., 96, 120, 479, 504.]

Banyan Tree, *bor, bar, bargat, but, bai, ranket, kangji, barelli, wóra, kurku, baagat, phagwari, wur, wad, ala, mari, ahlada, gilike mara, peralu, pyinyoung, maha-nuga, vata*, etc. A large tree which throws down numerous aerial roots from the branches. It is found in the Sub-Himalayan forests from Peshawar to Assam; in the deciduous forests of Bihar, Chota Nagpur, Orissa, Circars, Central Provinces, Bombay Presidency and South India; less commonly in evergreen forests and in the low country of Ceylon. It is wild, but doubtfully indigenous, and is also largely planted throughout India for its shade. *Indian Gardening* gives an account of the famous specimen in the Botanic Gardens, Calcutta; described also by Sir George King (1895) in the *Guide* to these Gardens.

It yields an inferior RUBBER. According to Hooper (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1905-6, 25), the latex contains only 12·4 per cent. of caoutchouc and 82·2 per cent. resin. Is employed in Lahore in the oxidation of copper. As a MEDICINE the juice is applied externally for pains and bruises, and used as an anodyne in rheumatism. An infusion of the bark is regarded as a powerful tonic in the treatment of diabetes. The leaves are heated and used as a poultice. The fruits ripen from March to June, according to locality, and are eaten in times of famine; it would moreover appear, in addition, that in many parts of the country the young tender shoots and leaves, as also the bark, are eaten. [*Agri. Ledg.*, 1904, No. 4.] The twigs and leaves are grazed as FODDER by cattle and elephants. The WOOD is of little value, but is durable under water and, therefore, utilised for well-curbs. If carefully cut and seasoned it can be made into furniture, and is sometimes employed for boxes and door-panels. The wood of the aerial roots is used for tent-poles, cart-yokes and banghy-poles. The banyan is one of the numerous hosts of the LAC insect. By the Hindus it is regarded as sacred, and plays a great part in connection with their religious ceremonies. [*Cf. Pliny* (Holland, transl.), i., 360; *Linschoten, Voy. E. Ind.* (ed. Hakl. Soc.), ii., 53-8; *Pyrard, Voy. E. Ind., etc.*, 1601 (ed. Hakl. Soc.), ii., 370, etc.; *Tavernier, Travels Ind.* (ed. F. C ric, *Linn.*; *Rec. Bot. Surv. Ind.*, i., 136; *Woodrow, Gard. in Ind.*, 1899, 451-3; *Firminger, Man. Gard. Ind.* (ed. Cameron), 1904, 211-3. This species is the Edible Fig of Europe, the Smyrna Fig, also *anjir, kimri, jagu, jagári, shimai-atti, tiethie, ten*. Several varieties are cultivated in many parts of India, especially in Baluchistan, Afghanistan and Kashmir.

A rich and mouldy soil is required with a considerable quantity of lime combined with thorough drainage. The trees are propagated by cuttings, of one-year-old wood, planted in shady beds in February. There should be about 10 to 12 feet between each root. As a fertiliser about 50 lb. of well-decayed village sweepings may be applied to each tree after the crop is gathered. The plant begins to bear FRUIT in the second or third year after transplantation and continues for twelve to fifteen years. It fruits twice a year. The first season commences in June-July, but it is not allowed to ripen lest it should injure the second crop, which commences in January and is by far the most valuable. Figs for drying should be cut from the tree and carefully placed in trays and boxes. To improve the colour and soften the skin, the figs, before drying, are sometimes exposed to the fumes of burning sulphur or are dipped in a hot solution of salt, saltpetre or lye; but the former practice gives the fruit a very unpleasant taste and is injurious to the health of the consumer. The drying ground should be a clean space outside the orchard where the figs may be exposed to the full rays of the sun. The figs should be turned twice a day at first, and once a day in the later stages. Drying within six or seven days yields the best quality. So far as India

Cultivation.

Edible Fruit.

Medicine.

is concerned it would appear that the most approved variety is that found at the village of Khed Shivapur, 14 miles south of Poona at an altitude of about 2,200 feet, but the fruit of Baluchistan, Afghanistan and Persia is superior to the Indian. As a MEDICINE, the dried fruit is demulcent, emollient, nutritive and laxative. [Cf. *Pharmacog. Ind.*, 1893, iii., 342-5; Eisen, *Handling and Curing of Figs*, in *Ind. Agri.*, Nov. 1, 1897, 348; April 1897, 128; Feb. 1, 1898, 57; Dutt, *Mat. Med. Hind.*, 1900, 291; *Repts. Agri. Exp. Stat. California*, 1894, 1896-8, 1900, 1903-4; *Cyprus Journ.*, 1905, ii., 76.]

Lac.
Fibre.

F. Cunia, Ham.; *Rec. Bot. Surv. Ind.*, ii., 65, 139; iii., 103; *Agri. Ledg.*, 1904, No. 4, 27-8. The *kheunau*, *dumbur*, *riu*, *kanhya*, *sangji kanai*, *poroh*, *ye-kha-ong*, *jonua*, etc. A moderate-sized tree of the Sub-Himalayan tract from the Chenab eastwards ascending to 4,000 feet, Bengal, Orissa, the Circars and Burma, usually on the banks of streams or in ravines. LAC is produced on this tree. A fibre is obtained from the bark which is used for tying the rafters of Native houses. The fruit ripens about July to October and is eaten in India, though somewhat insipid. The wood is not used economically. The leaves are rough and sometimes employed in place of sandpaper.

F. el tic, Roxb.; see India-rubber (pp. 651-5).

F. lo er t, Roxb.; *Rec. Bot. Surv. Ind.*, ii., 139, 188; iii., 103. It is found on the Salt Range, the outer Himalaya and Sub-Himalayan tract from Kashmir eastwards; in Assam, on the Khasia hills and in Bengal; in Burma, Central, Western and Southern India, and in Ceylon.

Gum.
Fruit.

Timber.
Dye.

It produces a viscid GUM which is made into birdlime; Hooper (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1906-7, 6) mentions that the latex contains only 4.9 per cent. caoutchouc and 94.0 per cent. resin. It bears large fruits in profusion, which ripen all the year round, are eaten both ripe and unripe, and are considered a useful famine FOOD, being ground to a powder and mixed with flour. The leaves are used for cattle and elephant fodder. The WOOD is not durable, but is utilised for well-frames and for rough purposes, such as outhouse doors and cross-pieces for carts. [Cf. *Pharmacog. Ind.*, 1893, iii., 338-42; Duncan, *Dyes and Dyeing, Assam*, 1896, 25; Innes, *Jungle Prod.*, 1897, 8, 11; Dutt, *Mat. Med. Hind.*, 1900, 321; *Agri. Ledg.*, 1902, No. 1, 53; 1904, No. 4, 28-30.]

Charcoal.

F. i fectori, Roxb.; *Rec. Bot. Surv. Ind.*, i., 94; ii., 138, 188, 340, etc. The *pilkhan*, *ramanjir*, *pakri*, *kaim*, *pakar*, *baswesa*, *prab*, *safed kabra*, *kangji*, *pepere*, *serilli*, *war*, *batbar*, *jangli pipli*, *trimbal*, *bassari*, *jovi*, *tsjakela*, *nyaunggyin*, *kalaha*, *plaksha*, etc. A large (at first often epiphytic) tree found in the Sub-Himalayan tract from the Salt Range to Sikkim, and thence throughout India, Burma and Ceylon. It is more commonly planted than wild. There are in India three varieties.

The bark is said to yield a fair FIBRE. The bark is one of the five known as *panchavalka*, or the five barks. The young shoots are eaten by the Natives, and the leaves make good elephant and cattle fodder. The WOOD is sometimes used for charcoal, but not otherwise. [Cf. Dutt, *Mat. Med. Hind.*, 1900, 235; Innes, *Jungle Prod.*, 1897, 9.]

Pipal.

F. reli io, Linn.; Cameron, *For. Trees Mysore and Coorg*, 1894, 283-4; *Rec. Bot. Surv. Ind.*, i., 70, 89, 185, 209, etc.; *Ind. Gard.*, March 1899, 87; Woodrow, *Gard. in Ind.*, 1899, 453. Known as the *pipal* or *peepul*, the *asvattha* of the classics, and by the following, among many other vernacular names:—*pīpal*, *ashvatha*, *aswat*, *hesar*, *jari*, *bor-bur*, *ali*, *arasa*, *rāi*, *rāgi*, *basri*, *haspath*, *nyaung-baudi*, *bo*, etc. A large tree (usually starting as an epiphytic) without aerial roots. It is found in the Sub-Himalayan forests from the Panjāb eastwards; Bengal, Orissa

and the Circars; Central India and Upper Burma. Is extensively cultivated and held sacred both by Hindus and Buddhists. Sacred.

The bark yields a tenacious milky juice, which hardens into a substance resembling CAOUTCHOUC. Hooper (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1905-6, 25) mentions that a sample examined by him contained only 12·5 per cent. caoutchouc and 84·8 per cent. resin. The stem has also been stated to afford a resinous GUM, used as sealing-wax and employed by artificers to fill up the cavities of hollow ornaments. In the *Ahmedabad Gazetteer* (iv., 24) it is said to give a wax which is used in staining ivory red, but as this tree is one of the chief sources of LAC, this gum may simply be the excretion of the lac insect and not a gum at all. Among the Santals the milky sap is known as *loré*. A birdlime is prepared from it, called *shelim* in the Deccan. From the bark a FIBRE is extracted, which was formerly made into paper in Burma and employed in the manufacture of the umbrellas of that province. The bark is a useful TAN and yields in boiling water a dye of a faint reddish-fawn colour. With other barks it is converted into a black DYE, while the root boiled in water with alum gives a pale pink on cotton cloth. The leaves, bark and fruit are all employed in Native MEDICINE. The small figs as also the bark are used as famine FOODS, and the twigs and leaves as elephant and cattle fodder. The WOOD is utilised for packing-cases and for fuel, occasionally also for charcoal. [*Cf. The Bower Manuscript* (Hoernle, transl.), 1893-7, 186; Duncan, *Dyes and Dyeing, Assam*, 1896, 25; Innes, *Jungle Prod.*, 1897-9; *Agri. Ledg.*, 1902, No. 1, 53; 1904, No. 4, 31; Joret, *Les. Pl. dans L'Antiq.*, etc., 1904, ii., 293-4.] Milky Sap. Gum. Lac. Fibre. Paper. Tan. Dye. Medicine. Fodder. Timber.

FI HAN FI H RI OF INDIA.—Day, *Fa. Br. Ind.* (Fish, D. P., 2 vols.); PISCES. The information available regarding the FISH and iii., 363-97. FISHERIES and the associated industries of India is very extensive and varied. Rule and Before*, 1901, i., 361-2.

The following are some of the chief commercial headings under which particulars regarding fish and fish products may be found in this work:—*êche-de-er* (p. 122); *Fish and Fisheries* (the present article); *Fish-aws and hark-fins* (p. 542); *Isinglass and Glue* (pp. 542-3, 695); *ils and Fats—Animal* (pp. 811-4).

Other kindred subjects are:—*Pearls and Pearl Fisheries* (p. 557); *hells: Conch, Chank, other-of-Pearl*, etc. (pp. 558, 989).

If may be said that while the products afforded by fish are many and varied, the information available regarding them is fragmentary and unsatisfactory. The majority of fish are of course cooked and eaten either fresh or after being salted, sun-dried, smoked, pickled, preserved in oil, etc., etc. But unfortunately it is next to impossible to learn actual particulars of the fisheries and fish-curing industries that could be regarded as of a practical and commercial value. Much has been published, but either of a purely scientific character or of a most discursive nature.

PRODUCTION.—Bengal.—In the trade returns of Bengal, for example, repeated mention is made of exports in dried fish and prawns. It is also known that a fair business is done in smoked, pickled or otherwise preserved mango-fish, *hilsa* (sable), and *begti* (cock-up), the last mentioned being often prepared in the form known as “tamarind-fish,” but nothing for certain is known of the sources of supply or the centres of manufacture in Bengal or even in Calcutta. It is recorded that Calcutta obtains fish from Goalundo, from East Bengal, from Diamond Harbour, from Mutta and other localities in South Bengal. Moreover, though repeated efforts have been made (and indeed are being made) to organise a systematic supply of sea-fish, the Calcutta market is almost exclusively met by fresh-water fish. The supply of excellent *begti*, procured both direct from the rivers or from special rearing-tanks, is very great and the quality excellent. During their respective seasons both mango-fish and *hilsa* are plentiful, the latter caught very largely in the Ganges and conveyed by special fish trains to Calcutta. Tank-reared fish may be spoken of as an important feature of the Bengal supply. The sale of live fry for the purpose of annually stocking tanks is accordingly a fairly important special industry. The fry are caught on the surface of the shallow water near sandbanks in the rivers, and are carried inland in earthen pots to be sold to the owners of rearing-tanks.

Upper India may be spoken of as entirely dependent on its rivers for its supply of fish. At one time a great effort was made to convey sea-fish from Karachi as far inland as Simla, but the venture was evidently not profitable as it was discontinued. The military stations of the Panjáb, however, do in some cases get fresh sea-fish from Karachi. Near the larger rivers the towns such as Lahore, Delhi, Agra,

engal.
Exports.

Calcutta.
Supply.

Tank Fish.

Upper
India.

Poor Supply.

Allahabad, etc., obtain a fair supply at certain seasons, but fish is by no means the important article of diet in Upper India that it is in the western, southern and eastern provinces. In Assam excellent river-fish may be had, one of the most highly prized being the *bassa*, which when smoked is an excellent addition to the breakfast table, and by some the King-fish—*Semiplotus maclellandi* (Day, l.c. i., 281)—or *sundari* is even more highly prized.

Assa .

Bo bay and Sind.—The trade returns of Bombay frequently make mention of *bummelo* ("Bombay duck"), "tamarind-fish" of various qualities, such as *seir* (white-pomfret)—the best quality. Bombay has an excellent supply of sea-fish, and accordingly fresh-water fish are nearly as rare in the western capital as sea-fish are in the eastern. Calcutta visitors to Bombay accordingly much appreciate the pomfret and sole they receive there, just as the Bombay visitors extol the Calcutta *begti* and mango-fish. Bombay oysters have, as a rule, an evil reputation among Europeans, but all the same there exist extensive beds for their production and a by no means unimportant traffic in that shell-fish. The exports to China of Shark-fins and Fish-maws (see p. 549) are by far the most important single item in the Bombay foreign trade in fish. Karachi holds, however, an even more important position in the fish trade of Western India than Bombay. The oysters of Karachi are regarded as the best in all India. The pomfret, sole and other fish procured in Karachi are excellent, and of a flavour only to be compared with those in the extreme south, such as at Cochin and Calicut. A large trade is at the same time done in shark-fins and fish-maws from Karachi, as also in Isinglass and Fish-oil (p. 545). The Persian Gulf traffic in salted and sun-dried fish is very ancient. Marco Polo (*Travels*, 1290 (ed Yule), i., 102, also n. 109) alludes to the people of Hormuz living on dates and salt fish. Date and dry-fish diet is alluded to also by Ibn Batuta.

Exports.

Oysters.

Madras.—This is perhaps the most important province in the fish trade of India. From ancient historic times the sun-dried, salted and pickled fish of the southern Malabar Coast have not only permeated over a large part of India but been carried to foreign countries. Difficulties in the Indian fiscal regulations with salt have for some years been loudly proclaimed as having restricted if not curtailed that industry, and the subject has received (and is receiving) the most careful consideration not only of the local but of the Imperial Government. The tamarind-fish of Cochin is chiefly made from the *seir*, and the fish-oil—so much extolled over India—is made mainly from the sardine (see *Oils*, pp. 544-5). Under *êche-de-er* (pp. 122-3) reference has been made to the Madras traffic in sea-slugs. Oysters are specially cultivated at several centres, and the supply is both large and excellent. South India has thus a liberal stock of most admirable sea-fish (pomfret, sole, sardine, etc.) of all kinds, and in the vicinity of its large rivers a supplementary supply of fresh-water fish. Important fisheries exist, as well as valuable industries in Pearls, Conch, Chank and Mother-of-Pearl (see p. 557).

outh
India.
Fish Curing.

Oil.

Liberal Supply.

Bur. a.—Speaking of Further India, the trade returns show a considerable traffic in locally produced sea-slugs, as also in foreign slugs imported and to a certain extent again re-exported. There are also valuable local fisheries and fish-curing centres in Burma. The salting and preserving of fish have in fact assumed special forms more or less characteristic. The *Gazetteer of Upper Burma and the Shan States* (ii., pt. i., 433)

ur a.
Sea-slugs.

gives, for example, a useful sketch of the fisheries and trade in fish on the Irrawaddy.

CHIEF INDIAN FISH AND FISHERIES.—The following are some of the more important aspects of the fish supply of India, of fish products, and of the special preparation of fish, met with in Indian commerce :—

1. **"BOMBAY DUCK" OR BUMMEL FISH.**—This is the fish—*Harpodon nehereus* (Day, l.c. i., 412), known in the vernacular as *nehare*, *bumalo*, *cucali sawakri*, *coco mottah*, *luli*, etc. It is common in the seas and estuaries of India, more especially Bombay. It is highly esteemed as food when eaten immediately after being caught. Since it rapidly goes bad, it is at once salted and subsequently sun-dried, and in that condition alone is known to most people. It is the relish served with curries that bears the name "Bombay Duck"—a quaint and obscure name that has an analogy in "Digby chicks." Boswell (*Tour to the Hebrides*, 1773) compares the Bombay ducks to the sun-dried whittings of Aberdeenshire, known as "Speldings."

River-fish.

2. **FRESH-WATER FISH.**—It would occupy much space to mention all the fish of this class that might be regarded as worthy of interest. A special feature of Indian rural life, and one that is capable of considerable improvement, is the rearing of fish in tanks, an industry already briefly alluded to. Tanks are necessities of life in large tracts of country in order to supply water, and that they are utilised as sources of edible fish is not only natural and economical but essential to the purity of the water. A large number of the Indian fresh-water fish naturally frequent backwaters of the rivers; in other words are not averse to live in tanks. This has led to the traffic already mentioned of catching and selling live fry with which to stock tanks that are even remote from the rivers. The following are some of the better known river-fish, many of which can be reared in tanks :—*Anabas scandens* (Day, l.c. ii., 367), the Climbing Fish or *coi*, *sennal*, *nga-pri*, *harlian*, etc.; these are often carried alive by the boatmen of the Ganges, being killed and cooked as required. They may be kept alive for a long time in damp earthen pots and thus conveyed to a distance. *Barbus*, the Carp: various species, especially *B. sarana* (Day, l.c. i., 300), the *sarana* or *durhie*, and *B. tor* (l.c. i., 307), the *mahasir*; most highly prized of sport-giving fish and found in hill streams. *Barilius bola* (l.c. i., 352), the trout of Indian streams.

Mahasir.

Hilsa.

Catla buehanani (l.c. i., 287), largely employed for stocking tanks in Bengal, United Provinces and Panjáb. *Clupea litsha* (l.c. i., 376), the *sable* or *hilsa*, a sea-fish that passes up most of the rivers of India and Burma, and is one of the most important of the fresh-water fishes. *Eutropichthys vacha* (l.c. i., 128), the *bassa* of Assam, is found in most of the larger rivers of India. *Labeo* (l.c. i., 256), the Kalban fish: several species are common in the rivers and much used for stocking tanks, such as *L. calbasu* (l.c. i., 259), Panjáb, Sind, Kach, Deccan, etc., *L. gonius* (l.c. i., 261), the *curra*, much used in the United Provinces, Bengal, Orissa, Ganjam and Kistna. *L. rohita* (l.c. i., 262), the *ruhu* or *ru*, an excellent fish, and accordingly carefully propagated in the tanks of Bengal. *Ophiocephalus* (l.c. ii., 360): several species of the so-called Walking Fish or Murrel, such as *O. barca* (l.c. ii., 361); may be carried in damp vessels for great distances, sold alive, and cooked as required. *O. marulius* (l.c. ii., 360) and *O. striatus* (l.c. ii., 363) are excellent for stocking tanks. *Pseudentropius takree* (l.c. i., 138), Poona and Deccan. *Rita buehanani* (l.c. i., 165), found in the Jumna, Ganges and Irrawaddy, is valuable for its capability of retaining life long subsequent to the removal from water.

Ruhu or Rui.

hark-fins.

3. **FISH-MAWS AND SHARK-FINS: ISINGLASS.**—The trade in these articles is a fairly ancient one. Milburn (*Or. Comm.*, 1813, i., 109, 283) makes reference to them. "Fish-maws," he says, "are an article of trade from various parts of China, where they are much esteemed." So again, "Shark-fins are an article of trade from the Arabian and Persian Gulfs and from thence to China; they are esteemed very strengthening by the Chinese." "They are likewise prepared on the Malabar and Coromandel Coasts and many of the islands in the Indian Ocean." The commercial products given as the title of this paragraph are not, however, the only products afforded by the group of fish placed in this position. The flesh (especially of the young) is often valued as an article of food; the fins are employed in making jellies and soups, mainly by the Chinese; the livers afford an oil, which when carefully prepared (more especially of certain species) is spoken of as a useful substitute for cod-liver oil; and the skin of most species is made into the substance known as SHAGREEN. The group of fish here indicated might be

Oil.

Shagreen.

defined as the Sharks, Ray-fish, Skates and Saw-fish. On the other hand, fish-maw, which in a purified form is known under the name of isinglass (or, to be more accurate, fish isinglass) is a substance usually obtained from a widely divergent assemblage of fish. It is simply the "sound" or "air-bladder" and might be prepared from almost any fish, though certain species are more highly valued than others. It may accordingly be desirable to refer these to two sections:—

(a) *Shark-fins*.—Day (*l.c. i.*, 3) wrote, "These fish are employed as food, and portions of them, especially the fins, are largely exported from the Indian to the Chinese markets. In China Dr. Cantor observed that the fins were not exclusively selected from the sharks—*Selachoides*—but equally from the rays—*Batoidei*. Among those examined at Penang were found to be fins taken from the fishes belonging to the following genera:—*Carcharias*, *Zygæna*, *Stegostoma*, *Pristis*, *Rhinobatus*, *Trygon* and *Myliobatis*. Gelatine is obtained from the larger fins, glue from the smaller. All except the caudal fins are cut from the fish at the root, so as to leave as little flesh as possible. The root is dipped into wetted lime (*chunam*) and then the fins are dried in the sun, and according to their value they are divided into two kinds: "white" and "black." The white consists exclusively of the dorsal fins, which are on both sides of a uniform light colour, and are expected to yield more gelatine than the other fins. The pectoral, ventral and anal fins pass under the denomination of "black fins"; the colour, however, varies from buff to grey or brown, and most of them are of two different colours, the upper surface being dark and the lower light. The black fins of course are the most numerous, and supposed to yield a comparatively small quantity of gelatine." In another passage Day (*l.c. i.*, 5) remarks:—"The fins of the sharks are removed and dried in the sun. Strips of the flesh are also salted as food and the livers boiled down for the oil they contain." "Some forms of large sharks, as *Galeocerdo*, which have the edges of their broad teeth sharp or coarsely serrated, cannot be captured by nets, as they at once cut their way out. But nets are suitable for such species as possess conical teeth; these last may likewise be taken by baited hooks attached to cords composed of many strands, through which the teeth penetrate but do not cut." A curious circumstance regarding the special nets used on the coast of Karachi may be here mentioned, namely that they are made very largely of the fibre derived from *Calotropis procera* (see p. 206), a fibre hardly utilised in any other part of India, but the place of which is taken in Eastern India by reha fibre (see p. 157), both fibres being selected on account of their great strength and durability under water.

The following are the chief Indian fish that afford "Shark-fins":—*Aëtobatis narinari* (Day, *l.c. i.*, 59), the Devil Fish; *Bagarius garrellii* (*l.c. i.*, 194), the fresh-water shark, the *bunch* or *gunch*; *Carcharias acutidens* (*l.c. i.*, 11), a shark of the coast of Sind and the Indian Ocean; *C. gangeticus* (*l.c. i.*, 13), one of the most ferocious of Indian sharks; *C. limbatus* (*l.c. i.*, 17); *C. melanopterus* (*l.c. i.*, 14), *caval sorrah* or *raman sorrah*; and *C. menisorrh* (*l.c. i.*, 16); *Pristis cuspidatus* (*l.c. i.*, 37), the Saw-fish; *Pteroplatea micrura* (*l.c. i.*, 56); *hynchobatus ancylostomus* (*l.c. i.*, 41), the Mud-skate; *R. djeddensis* (*l.c. i.*, 40), the *ulavi* or *ranja*; *Trygon sephen* (*l.c. i.*, 50), the Ray; *T. uarnak* (*l.c. i.*, 53), the *sankush*, *hankus*; and *Zygæna malleus* (*l.c. i.*, 22), the Hammer-headed Shark.

(b) *Fish-maws and Isinglass* (see Isinglass, p. 695).—Vulgarly the term Isinglass is sometimes given to Mica. The English word is a corruption of the Dutch *huisenblas* (=sturgeon-bladder). It may be obtained from many substances, and according to the Greeks it was *icethyocolla* or fish-glue. As already explained, the finer qualities are the "sounds" or "air-bladders" of fish. The true isinglass of European commerce is the sound of the sturgeon (*Acipenser*), Brazilian isinglass is derived from one or two species of *Silurus*, and the Indian isinglass from one or other of the following fishes:—*Arius acutirostris*, *burmanicus*, *celatus*, *falcarius*, *gagora*, *sona*, and *sagor* (Day, *l.c. i.*, 173–88). These are largely prepared and salted on the Western Coast (Karachi), but at the mouths of the Ganges there is also a fair and improving trade:—*Osteogobius militaris* (*l.c. i.*, 190); *Otolithus maculatus* (*l.c. ii.*, 127), the *birralli* of Orissa; *O. ruber* (*l.c. ii.*, 128), the *jarang-gigi* (or *pêchepierre*) of Pondicherry; *Pristipoma guoraca* (*l.c. i.*, 512), the *gouraka*; *Serranus diacanthus* (*l.c. i.*, 449), the *damba*; *Silundia gangetica* (*l.c. i.*, 145); and the *Umbrina russellii* (*l.c. ii.*, 110). [Cf. Royle, *Prod. Isinglass*; Day, *l.c. (Fishes) i.*, 3, 5, 7–63; Hunter, *Imp. Gaz.*, iii., 434.]

4. *FISH MANURE*.—When procured in excess of demand for human food, large

quantities of fish are utilised as manure near the coast towns of India, very much as in some parts of Europe. Thurston (*Bull. Mad. Mus.*, 1900, No. 2., 120-3) gives much information on the extent to which the sardine is employed as manure, the supply ranging from 2 to 515 tons a year. Fish manure is not unknown to the coffee planters, and Mollison says that for sugar-cane culture this manure is much valued. The Malayas consider the fish *Echeneis naucrates* (l.c. ii., 214) as specially suitable as a manure for fruit trees. [Cf. Simmonds, *Waste Prod.*, etc., 155-77; Lehmann, *Rept. Agri. Cult. Chem. Mysore*, 1901-2, 14; Mollison, *Textbook Ind. Agri.*, i., 107-8.]

medicine.

Indian Cod-liver
Oil.

5. *MEDICINE*.—The bile of certain species of fish is believed to be a valuable medicine, especially that of the *ruhu* or *rui* (*Labeo rohita*). [Cf. Taleef Shereef, (Playfair, transl.), 1833, 150.] The brine of pickled fish is alluded to by Paulus Aegineta (Adams, transl., iii., 81). Fish diet is by the Hindus considered safer for invalids than the flesh of other animals. The oil prepared from many species is used as an efficient substitute for cod-liver oil.

Ngapee.

6. *NGAPEE* (*Ngapi*).—In an official report issued in 1902 (though not offered for sale) by the Government of Burma on the Inland and Sea Fisheries, reference is made to the account of this preparation as given in the *Dictionary*. The passage in question was reprinted direct from the description of Tenasserim, written by H. Fenwick in 1849—presumably an authority on Burmese matters of the date in question. The recent official publication enumerates and describes some eighteen different forms of *ngapi*, the particulars given occupying five pages of closely printed foolscap. It concludes by asking the question, "Why does *ngapi* smell, it will be asked? Because, however carefully the stuff is made, there must be always a considerable proportion of uncured flesh, flesh that the salt cannot reach. This flesh decays and rots, but the rest is properly cured fish."

Small of.

To many persons preserved fish in any form is objectionable. The danger of eating a proportion of rotten uncured flesh, however small, may be suggestive of poison and doubtless dictated the appellative "semi-putrid fish" used by Fenwick. The following passage from Nisbet (l.c. i., 361) fairly represents all that is known regarding the preparation of *ngapi*. "Immediately after being caught and brought to land the fish are either scaled by hand or have the scales roughly brushed off with a frayed bamboo, and are then thrown into a wooden trough, the larger being gutted and deprived of head and fins. After being rubbed with salt they are packed in baskets and pressed down by means of a board weighted with large stones. Next morning they are unpacked and again rubbed with salt, then spread out on thin bamboo mats to dry in the sun until the afternoon of the following day, when they are packed alternately with layers of coarse salt in large earthenware jars placed in the shade. To retard the process of liquefaction of the salt, the powdered bark of the *ondon* tree (*Litsea sebifera*) is mixed with it; but, during the three to five weeks this rough method of pickling is allowed to continue, the oily brine oozing to the top and evaporating, sometimes becomes so full of maggots before drying up that fresh supplies of salt have to be added. The scaleless siluroid mud-fishes are those most easily treated in this way."

Preparation.

Ngathalaik.

"Greater care is taken in the preparation of *ngathalaik* (*Clupea palasah*), the *hilsa* of Indian rivers, which are simply gutted but not otherwise cleaned, and then salted and sun-dried before being spread between thin bamboo mats and pressed for about three days. These dried fish (*ngachauk*), the daintiest of Burmese condiments, are both in preparation and in transport handled separately, whereas the stinkingly offensive *ngapi* is sold in bulk, in baskets and sacks. Both varieties are cooked by roasting or frying when used to flavour the meal of boiled rice."

Fish-paste.

"Along the Tavoy and Mergui coast a finer quality of fish-paste is made with shrimps and prawns, which are worked up with salt when half-dried in the sun. As this is eaten uncooked, it is termed *seinsa* or 'raw food.' The more carefully prepared paste, made with selected small prawns, is frequently used with curry and rice as a chutney by Europeans all along the Malay coast, where it is known as *balachong*; and of recent years it has competed with caviare as a *bonne bouche* in the boulevard restaurants of Paris." [Cf. Mandelslo, *Travels*, 1639, in Olearius, *Hist. Muscovy*, etc., 121; Symes, *Emb. to Ava*, 1795, ii., 371; Crawford, *Journ. to Ava*, 1834, ii., 176; *Gaz. Upper Burma and Shan States*, ii., pt. i. 433.]

7. *FISH-OIL* may be referred to two sections:—

Balachong.

D. P.,

ii., 155;

iii., 36 ,

375- ,

37 , 462.

Fish-oils.

(a) *Shark, Ray and Skate Oils*.—These are sometimes treated separately or mixed (as procured). In the former case an oil is often prepared from some of the

species that might be used as a substitute for cod-liver oil. Thus, for example, Day (*l.c. i.*, 5) says: "At Calicut, medicinal fish-liver oil of an excellent quality was formerly manufactured, a small factory for this purpose having been constructed at that station in 1854, and the livers of sharks and saw-fishes were purchased from the fishermen. The abundance or paucity of these fishes evidently depended to a very great extent upon whether sardines were or were not present, for these latter forms of *Clupeide* are very capricious, sometimes forsaking the coast for several successive years, and then as suddenly reappearing in countless millions. No livers under 40 lb. weight were accepted at the factory, as the larger ones gave proportionally a greater amount of oil than the smaller ones; sometimes livers of a great size were purchased. One weighed 290 lb., and another from a female saw-fish, 14 feet long, 185 lb." The fish included in this paragraph have been enumerated under Fish-maws and Shark-fins above.

(b) *Other Fish-oils*.—The livers, or the whole fish, of certain species that do not belong to the above group are known to afford excellent oils. These are mainly used for illuminating purposes, but some are of superior quality and may be even employed as articles of food. Such oils appear to be made of salt-water fish, all along the coast of India, and from fresh-water species, along the channels of the chief rivers. The following are the fish most highly spoken of as affording oil:—*Barbus chota* (*l.c. i.*, 317), the Bitter Carp of the rivers of India; *Clupea ambriata* (*l.c. i.*, 373), the Sardine; *C. tilsha* (*l.c. i.*, 376), the Sable or *Hilsa*; *C. tongiceps* (*l.c. i.*, 373), the Malabar Oil Sardine; *Cybinum commersonii* (*l.c. ii.*, 211), the Seer or *konam*; *Labeo rohita* (*l.c. i.*, 262), the *ruhu* of Indian rivers; *Silundia gangetica* (*l.c. i.*, 145), found in the estuaries of India and Burma, the oil of which is much valued as a medicine.

Trade in Oil.—Thurston gives the fullest and most recent account of the Fish-oil trade of India. The following passage may, therefore, be abstracted from his most interesting and useful report:—"Hundreds of tons of fish-oil are said to have been annually exported from Cochin in former years, and I find that the average export thereof in the five years 1856 to 1861 was 19,630 cwt. The oil trade is, however, reported to be decreasing year by year. In some seasons the sardines arrive off the coast in enormous numbers, or, for several years consecutively, they may be present only in quantities sufficient for purposes of food. The result of this irregularity is that one very important element of success in commercial undertakings—regular supply—is wanting. In some years large shoals of sardines appear, and suddenly disappear. Contracts for the supply of oil are made on the arrival of the fishes, and, in the event of their disappearance, the contractor loses heavily. The Natives of Cochin say that formerly the sardines always arrived regularly, and remained throughout the season. And the fishermen's belief is that they are at the present day frightened away by the numerous steamers which call at Cochin, and retire in search of a less disturbed spot. In addition to steam-boat traffic, noises in boats, ringing church bells, artillery practice, the erection of lighthouses, gutting fish at sea, using fish as manure, burning kelp, and the wickedness of the people, have been charged with being responsible for a falling off of the fish supply. But, as Mr. Fryer naively remarks, of these alleged causes, only the last, it is to be feared, has been, and is likely to be, a permanent factor in the case."

"The preparation of the evil-smelling fish-oil is carried out in large iron cauldrons, in which the fish are boiled with a little water. The oil, as it exudes, rises to the surface, is strained through cloth, and stored in barrels. The residue in the cauldrons is preserved, and utilized as manure for cocoanut gardens, paddy (rice) fields, etc. A rougher and cheaper process of oil-extraction, by which the cost of cauldrons and firewood was saved, has practically been put a stop to as being an offensive trade. This process consisted simply in putting the fishes into a canoe, and exposing them to the influence of the sun until decomposition set in. The oil then rose to the surface, and was removed with a scoop. By this crude process a comparatively small quantity of the oil was extracted. A portion of the manufactured oil is consumed locally by boat-owners for smearing their boats, so as to preserve the wood and coir ropes (made from the fibre of the cocoanut husk) with which the timbers are stitched together. But the bulk is exported to Europe and some Indian ports. The Natives believe that the oil returns from Europe, disguised in the guise of cod-liver oil." [*Cf. Eastern India*, i., 229; Buchanan-Hamilton, MS. pub. by Day in Hunter, *Stat. Acc. Beng.*, xx., 85; *Japanese Sardine Oil*, in *Journ. Soc. Chem. Indust.*, 1887, vi., 372; Thurston, *Bull. Mad. Mus.*, 1900, No. 2.]

8. **POISONS OR INTOXICANTS USED TO KILL FISH.**—The following are the plants often used in India to kill fish:—*Albizzia stipulata*, and *procera*; *Ananirta Cocculus*, W. & A. (the seeds boiled in rice and made into a paste); *Balanites Roxburghii*, Planch; *Barringtonia racemosa*, Bl. (seeds mixed with bait); *Bassia butyracea*, Roxb. (bark used in Sikkim); *Berberis aristata*, DC. (bark); *Crotalaria paniculata*, Willd. (according to Hooper, plant used); *Derris elliptica*, Benth. (bark and flowers); *Diospyros montana*, Roxb. (fruits); *Euphorbia Tirucalli*, Linn.; *Fluggea Leucopyrus*, Willd., and *F. microcarpa*, Bl. (the barks); *Gynocardia odorata*, Br. (the fruit); *Hydnocarpus venenata*, Gaertn. (fruit used); *Lasiosiphon eriocephalus*, Dene. (bark); *Millettia Piscidia*, Wight (powder of bark and flowers); *Mundulea suberosa*, Benth. (seeds and inner layer of bark); *Randia dumetorum*, Lamk. (bruised fruits); *Saptum indicum*, Willd. (the seeds used); *Spilanthes Aemella*, Linn. (fruits); *Strychnos Nux-vomica*, Linn.; *Walsura Piscidia*, Roxb (bark thrown into tanks).

It has been pointed out that many of these contain saponin. All are more or less acrid and bitter. It is generally held that the fish taken by this process are quite wholesome. The practice is most reprehensible, since young and old are killed and more therefore destroyed than can be used. [Hooper, *Drugg. Bull.*, Nov. 1890.]

9. **ROE.**—The roes of certain fish are highly prized. They are often specially prepared and sold by themselves, just as in Europe the cod-roe is a recognised marketable article. The fish most generally resorted to for this purpose are the Gard fish of Malabar (*emirhamphus buffonis*) (l.c. i., 427), a fish found plentifully in the seas and tidal rivers of Bombay, Bengal and the Andaman Islands. So again the Corsula Mullet (*Mugil corsula*) (l.c. ii., 349) or the *undala*, *corsula*, *in-ge-li*, *nga-sheng*, etc., which Ainslie says affords a kind of caviar (caviare), as also the Common Mullet (*Mugil eur*) (l.c. ii., 348), the *kola-kende* or *muhlah*, yields roes that are much appreciated and are sold sun-dried.

caviare.

Dried Fish.

10. **SALTED AND DRIED FISH.**—In official statistics this subject is dealt with under the following headings:—"Dry Unsalted Fish," "Dry Salted Fish," and "Wet Salted Fish." One of the most startling circumstances of the trade in fish is the fact that India is apparently not able to meet her own demands. Perhaps no other part of the globe (of a like magnitude) possesses so varied and extensive a series of marine and fresh-water edible fish, nor so many forms that lend themselves readily to artificial production in tanks and ponds. In spite of every advantage, however, the foreign imports far exceed the exports, thus showing that from one circumstance and another, India is not self-supporting in the matter of fish. Whether this proceeds from unskilled methods and imperfect appliances, or from the want of proper regulations and protective measures, in the form of a Fisheries Act, or from the restrictions that prevail in the supply of cheap salt for fish-curing, or from the climatic and social conditions of the country and people that are naturally opposed to the development of a fish-curing industry, are points of a highly controversial nature. The late Dr. Francis Day was of opinion that the Bengal supply had steadily declined, since the first decade of the nineteenth century, when Buchanan-Hamilton conducted his survey of that province and wrote his *Fishes of the Ganges*, owing, Day thought, to the selfish and destructive systems that were allowed to prevail. Be that as it may, it is certain that the past twenty or thirty years has witnessed the steady growth of an import trade in fish which has assumed no mean proportions.

India imports
Fish.

Explanation.

The following, arranged in alphabetical sequence of their scientific names, are the more important fish sold in salted condition:—*Aëtoabatis narinari* (l.c. i., 59), the Devil Fish; *Arius celsatus* (l.c. i., 174), *A. sapor* and *A. sona* (l.c. 178-9); *Chatoessus chacunda* (l.c. 386), the Indian Herring; *Chrysophrys berda* (l.c. ii. 44), the Grey Perch; *Clarius magur* (l.c. i., 115); *Cytlum guttatum* (l.c. ii., 210), Seer or seir; *Cynoglossus* sp. (l.c. ii., 452), the Soles known in South India as *mānthāl*; *Equula daura* (l.c. ii., 188), the *dacer karah*, Coromandel; *Gerres filamentosus* (l.c. i., 537), the Udān; *Harpodon nehereus* (l.c. i., 412), the Bummelo, already discussed; *Lutjanus argentimaculatus* (l.c. i., 472), the Red Rock-cod; *L. jahngarah* (l.c. i., 474), the *purruwa*; *Mugil corsula* (l.c. ii., 349), the Mullet; *Pristis cuspidatus* (l.c. i. 37), the Saw-fish; *Rhynchobatus djeddensis* (l.c. i., 40), the *ulavi*; *Saccobranchus fossilis* (l.c. i., 125), the Scorpion Fish; *Sciæna bleekeri* (l.c. ii., 112), the *soh-li*; *Scomber microlepidotus* (l.c. ii., 203), the Mackerel or *ila*; *Stromateus cinereus* (l.c. ii., 198), the Silver Pömfrët; *S. niger* (l.c. ii., 199), the Black Po fret; *S. sinensis* (l.c. ii., 197), the White Pömfrët; *Trachynotus ovatus* (l.c. ii., 179), the

kutili or *mukali-parah*; *Trichiurus haumela* (l.c. ii., 134), the Puttiah; *Trichogaster fasciatus* (l.c. ii., 372), the *kolisha*, *nga-phyin-thaleb*—one of the fish made into *ngapi*; *Trygon uarnak* (l.c. i., 53), the Ray-fish, *sankush*.

Thurston (l.c. 1900, No. 2, 116 *et seq.*) should be consulted for particulars of the Indian methods of fish-curing. The bulk of the traffic, he says, takes place between September and March.

11. **FISH SCALES.**—The scales of the *mahasir* (*Barbus tor*) are said to be employed in the manufacture of playing-cards. They are cut into circular pieces about $1\frac{1}{2}$ inch in diameter, painted and varnished. The centre of the trade in this curious commodity appears to be Shahabad. In the Deccan the large scales of a carp are used in place of glass for windows. The scales of the Bleak and the Dace are in Europe employed in the production of a substance known as Essence d'Orient which is utilised in the manufacture of artificial pearls. [Ind. Art at Delhi, 1903, 202-5.]

Playing-cards.

Artificial
Pearls.

12. **SEA FISH.**—So many of the fish that should fall into this position will be enumerated under other headings that it is hardly necessary in this place to do more than mention a few of the more important species:—*Atherina forskalii* (l.c. ii., 338), also *Engraulis indicus* (l.c. i., 394), both called Whitebait by Europeans in India; *Chanos salmoneus* (l.c. i., 403), the Milk Fish or White Mullet; *Chatoessus chacunda* (l.c. i., 386), the Indian Herring; *Clupea fimbriata*, *tile* and *longiceps* (l.c. i., 373-4), Sardines; *Cybium guttatum* (l.c. ii., 210) and *C. commersoni* (l.c. ii., 211), *seir*; *Cynoglossus lingua* (l.c. ii., 454), the Sole of Europeans in India, or *kot-arali*, a fish highly esteemed in the coast towns of India; *Dussumieria acuta* (l.c. i., 399), the Malabar Sardine; *Harpodon nehereus* (l.c. i., 412), Bombay Duck; *Lates calcarifer* (l.c. i., 440), the Cock-up or *nair*, the *begti*; *Mugil corsuta* (l.c. ii., 349) and other species, the Mullet; *Polynemus indicus* (l.c. ii., 105), the Rowball of Vizagapatam, the *selé*, is one of the chief sources of the "Fish-maws"; *Scomber microlepidotus* (l.c. ii., 203), the Mackerel; *Silago sihama* (l.c. ii., 224), the Whiting of Europeans in Madras; *Stromateus cinereus* (l.c. ii., 198), the Silver and Grey Pomfret; *S. niger* (l.c. 199), the Black Pomfret; *S. sinensis* (l.c. 197), the White Pomfret; and *Upeneoides vittatus*, the Mullet (l.c. ii., 25).

13. **SHAGREEN OR FISH-SKINS.**—The rough skins of many species of fish are used as a kind of sand-paper, and that of certain sharks, rays and skates is made into the substance known as shagreen. This is a thick skin covered with hard enamelled papillose scales. After being cured and stained it is employed to cover boxes, scabbards, sword-handles and other such purposes. In some respects the shagreen from the ray-fish and certain species of dog-fish is regarded as superior to that of the shark. In Hunter (*Imp. Gaz.*, x., 252) mention is made of shagreen manufactures at Nawanagar; also in Milburn (*Or. Comm.*, ii., 511), Horse-skins. The following afford shagreen:—*Pristis cuspidatus* (l.c. i., 37), the Sawfish; *Rhynchobatus acyllostomus* (l.c. i., 41), the Mud-skate; *Trygon sephen* (l.c. i., 50), the Ray; *Zygena malleus* (l.c. i., 22), the Hammer-headed Shark. Hoey (*Monog. Trade and Manuf. N. Ind.*, 1880, 94) describes the process of making horse or asses' hides into an imitation shagreen known as *kimukht* and *kirkin*.

hagreen.

Imitation.

14. **SMOKED FISH.**—While the art of curing fish by smoking them seems to have been known to the Natives of India from fairly ancient times, it cannot be said that it has assumed a position of such importance as in Europe. The *hilsa* or Sable, *Clupea ilisha* (l.c. i., 376), is the fish most noted as being in India cured by being smoked. The Mango-fish, *Polynemus indicus* (l.c. ii., 105), is a fish that must be eaten immediately after being caught. Accordingly, to allow of its being carried to a distance it is sometimes smoked. The *bassa* of the rivers of Assam, Bengal, Orissa, etc., is also a fish often smoked, but these and other instances are more a consequence of special demand by the Europeans than a regular Native industry. The smoke from burning refuse sugar-cane is that most generally used.

moked
Fish.

15. **SOAP.**—Several methods of utilising fish and fish-offal in the production of soap have been discussed by several writers, but no actual industry exists in India for this purpose. [*Cf. Simmonds, Waste Prod.*, 148.]

16. **TAMARIND-FISH.**—Fish pickled in a preparation of tamarinds is known in Indian trade by this name (see p. 1067). The species most frequently treated in this way are *Cybium guttatum* (l.c. ii., 210), the *seer* or *seir* fish, and *Lates calcarifer* (l.c. i., 440), the Cock-up or Nair fish, the *begti* of Bengal. Thurston says: "In

Ta arind-
Fish.

the ordinary method of preparation, the fish is boiled, and, after removal of the bones, cut in thick slices, highly spiced and left to soak, packed in a jar. But the following account of a new and improved process has been sent to me by Mr. Sherman. "Fish of all sizes can be cured, but, for Colombo market, mackerel are preferred. The fish are not slit open, but neatly gutted by extracting the entrails through the gill-opening. They are then carefully washed and packed, with alternate layers of salt, in big casks, which are procured locally and sold in Colombo with the fish. To each maund of the fish about 7 lbs. of tamarind fruit (*goosakapully*) are used." "The casks are stored on end and filled to the full. The fish is allowed to soak and pickle for four days, and the brine is then drawn off until it is about a foot from the bottom, and thus leaving enough brine to keep the whole cask moist when closed. Under this new system 1,658 mds. 5 seers of mackerel, with 375·7 mds. of salt are used, or 18·6 lbs. per maund against 12·5 lbs. used in the usual west coast method of curing."

Yards.

Provision of
Salt.

TRADE IN FISH.—It has often been urged that India is most neglectful of her food resources in this direction. With a little care the rivers and tanks might become very much more important sources of supply, and indiscriminate and wasteful methods of fishing, both in fresh and sea water, account largely for the backwardness of the trade. It has accordingly been urged that both a Fisheries Department and Fisheries Act are much needed. Repeated efforts have been made and voluminous reports prepared with a view at least to secure for each province a special Act to protect its fisheries (see p. 546). The multifarious vested interests of a vast population of semi-educated people are the excuses for existing defects. It has been said that when the people have come to appreciate the value of measures to secure and protect their interests, then will be the time for special legislation; and further, that without a proper Act a Fisheries Department would have little justification for its existence. On the other hand, the claims of the fish-curing industries have already been recognised by the organisation of Government fish-curing yards where cheap salt may be supplied, under regulations that ensure its being restricted to the purpose intended, and these have been placed under the control of the Salt Department. But in the annual publication *Financial and Commercial Statistics of British India*, no factory or establishment that employs less than 25 persons permanently is recognised, hence the bulk of the fish-curing yards are excluded. Fish-curing in India, though important in the aggregate, is a domestic rather than a public concern. Nevertheless, in the publication mentioned, there were recorded 10 companies in 1901, 15 in 1903, and 13 in 1904, employing on the average about 1,300 persons annually. These were entirely in the Madras Presidency. In 1882 the prohibition against the use of natural saline earth in the preservation of fish was issued. This of necessity led to some provision to replace that material and method of fish-curing. This was met by the Salt Department concerning themselves with the provision of the fish-curing yards to which reference has been made. The salt issued to the fish-curiers was at first given at cost price, but in consideration of the fact that the saline earths formerly employed were procured for the cost of collection, the salt was reduced to 6 annas 8 pies per maund (say 6½d. for 80 lb.). It was found, however, that all forms of salt were not equally serviceable for fish-curing; accordingly for some years complaints were general, and a decline in fish-curing having occurred, this was pointed to as a direct result of the Government's efforts at protecting its salt interests while at the same time raising the standard of fish-curing in India. This subject will be found dealt with in some detail by Thurston. [*Bull. Mad. Mus.*, 1900, No. 2, 147-52.]

FISH-CURING

FI H
Trade

From the reports of the Madras Salt Department we learn that 136 curing yards had been organised at convenient centres along the west and east coasts of the Presidency. In 1902-3 the total amount of fish brought to them to be cured came to 50,374 tons, as against 68,992 tons in the previous year. The production came to 814,716 maunds of cured fish, of which it is stated 631,277 maunds were consumed in the Presidency. Thurston gives the returns of the three most important fish as follows:—Sardine, 387,300 maunds in 1896, 253 600 maunds in 1897, and only 31,000 maunds in 1898; Mackerel for these same years, 253,857, 90,035, and 401,946 maunds respectively; and *Seir*, 12,388, 24,321, and 8,088 maunds respectively. It would appear that from 60 to 65 per cent. of the South Indian fish-curing is done in the Salt Department Sub-Division of Calicut (including Malabar and South Canara), such as Calicut, Cannanore, Mangalore and Malpe, etc. There are several other important centres such as Chicacole, Tinnevely, Cocanada, Chingleput, Nellore, Negapatam, etc. Malpe is interesting as the centre to which the fishermen of Ratnagiri and Goa come for the *seir* fishing season. [*Cf. Memo. prepared by Finance and Commerce Dept. Ind. on the Salt Dept., Sept. 1894, 42-3.*]

N ber of
Yards.

Amount Cured.

Proportion of
Each Kind.

The internal traffic in fish, as in most other Indian commodities, can alone be studied by the perusal of the official statistics of Foreign and Coasting Trade. Fish do not appear in the returns of *Rail and River-borne Traffic*, so that very little can be learned of the internal transactions. The following are the headings under which they are recorded:—(a) Fish-maws and Shark-fins; (b) Fish, Dry Unsalted; (c) Fish, Dry Salted; (d) Fish, Wet Salted; and (e) Fish-oils.

Official
tatistics.

Trade in Fish-aws and Shark-fins (see p. 542).—India imports on an average $5\frac{1}{2}$ lakhs of rupees' worth. These come from Aden, Arabia, Mekran and Sonmiani, Persia and Zanzibar. The highest record during the six years ending 31st March, 1907, was in the year 1901-2, when the imports stood at 1,797,114 lb., valued at Rs. 6,58,200; of that amount Bombay took 1,755,877 lb., valued at Rs. 6,27,554, and the balance went to Sind, Madras and Burma. The imports during the years 1903-7 have been:—1903-4, 1,588,692 lb., Rs. 5,87,444; 1904-5, 1,330,326 lb., Rs. 5,05,193; 1905-6, 1,388,365 lb., Rs. 5,25,394; and 1906-7, 1,215,972 lb., valued at Rs. 4,84,465. Practically the entire imports are re-exported, and from 6 to 14 lakhs of rupees' worth of Indian produce exported at the same time. This may approximately be said to represent on the average a total EXPORT traffic of 20 lakhs of rupees in value. Thus, taking the year 1903-4, the foreign shark-fins and fish-maws re-exported came to 1,878,342 lb., valued at Rs. 14,36,580, and the exports drawn from Indian supplies came to 481,873 lb., valued at Rs. 5,14,006; and in 1906-7 the re-exports came to 1,350,020 lb., Rs. 11,73,345, and the exports 565,435 lb., Rs. 5,13,350. Bombay is of course the chief exporting province, and exported out of the totals mentioned, in 1903-4, 1,876,074 lb. foreign shark-fins and fish-maws and 49,520 lb. Indian; in 1905-6, 1,336,804 lb. foreign, but no Indian; but Bombay, however, is by no means the most important exporting centre for the Indian fish-maws and shark-fins. In the Indian produce traffic, Burma usually heads the list, and in 1903-4 exported 281,296 lb., in 1905-6, 243,592 lb.; being followed by Madras with 107,582 lb. and 153,614 lb.; Karachi with 14,923 lb. and 113,804 lb.; and lastly Bengal with 28,552 lb. and 14,768 lb. in the two years mentioned. The most important receiving country is of course

I ports.

xports.

China (Hongkong) for the re-exported fish-maws and shark-fins, followed by the Straits for the Indian. It is perhaps a significant circumstance that the United Kingdom has for some years taken fairly large quantities and even the United States have obtained supplies of these products direct from India.

Coastwise
Traffic.

As giving a fuller conception of the Indian production, the following review of the traffic carried coastwise may be framed. In the year 1903-4 the total coastwise transactions came to 1,236,173 lb., valued at Rs. 6,84,179, but showed a decrease in 1905-6 to 875,927 lb. Of the amount for 1903-4 Bombay alone took 1,160,667 lb., valued at Rs. 6,29,229. Of these coastwise imports two-fifths came from Madras, one-fifth from Sind, the remaining two-fifths equally from British ports and non-British ports within the Presidency of Bombay. The remainder, over and above the Bombay transactions on total coastwise trade, may be said to be imports taken in 1903-4 by Burma from Madras and Bengal, viz. 47,057 lb. Practically, therefore, the coastwise trade in shark-fins and fish-maws is concentrated in Bombay. It has been fairly constant for some years past, but if anything has manifested a tendency in the foreign imports to decrease and the Indian produce to expand, a satisfactory state of affairs.

Trade in Fish.—(b) to (d) above may be exhibited as follows :—

Imports.

Foreign I ports.—In 1892-3 the imports of fish were valued at Rs. 28,80,269 (say £193,000). Of that amount the "Unsalted Dry Fish" (see p. 542) came to Rs. 3,55,893, "Salted Dry Fish" (see p. 546) to Rs. 18,08,491, and the "Wet Salted Fish" (*Ngapi*, p. 544) to Rs. 7,15,885. In the years 1894-7 a serious decline took place in the traffic, due, it is believed, to the conditions that then prevailed in Bombay.

ANALYSIS OF THE IMPORTS OF FISH INTO INDIA.

YEAR.	DRY UNSALTED.		DRY SALTED.		WET SALTED (NGAPI).	
	lb.	Rs.	lb.	Rs.	lb.	Rs.
1900-1901	2,324,146	1,14,408	15,765,445	17,68,132	10,549,851	4,31,386
1901-1902	4,253,821	2,26,133	17,253,310	21,68,682	13,411,608	5,34,258
1902-1903	2,963,683	1,79,336	15,039,558	19,71,890	15,896,408	6,03,395
1903-1904	4,742,367	2,48,556	11,837,341	15,35,368	10,688,268	4,38,140
1904-1905	2,379,140	1,60,560	16,339,925	20,37,946	11,204,395	4,59,723
1905-1906	4,192,663	1,94,403	18,088,861	26,56,013	10,903,845	4,36,053
1906-1907	3,889,293	2,59,441	14,404,955	18,98,054	8,711,021	3,86,850

Striking
Features of
Burmese
Traffic.

Another very significant circumstance in the fish trade of India may be stated to be the fact that Bengal practically takes no part in the import traffic. Burma receives by far the major portion of all the fish imported by British India; and, what is most striking, its supplies come almost entirely from the Straits Settlements, and are uniformly returned at a much higher price than the classes of fish that go to the other provinces. Bombay is the chief receiving province for "Dry Unsalted Fish" and Burma for "Salted Dry" and "Salted Wet Fish." The imports of "Dry Salted Fish" come mainly from the Straits (into Burma) and from Arabia, Mekran and Sonmiani (into Bombay).

Exports.

Foreign Exports.—There exists a small re-export of foreign preserved fish which in 1905-6 came to Rs. 44,584, and in 1906-7, 22,686. But turning from these unimportant transactions to the traffic in Indian produced and preserved fish, it may be said that, if anything, the exports of "Dry Unsalted" and "Dry Salted Fish" from India have shown a tendency to improve during the past decade. In 1892-3, for example, they were valued at Rs. 8,97,406; in 1903-4 they came to Rs. 17,75,722;

and in 1906-7 to Rs. 15,64,747. The "Dry Unsalted Fish" goes usually in almost equal proportions and value from Bombay and Madras (in 1906-7, the Bombay share came to 1,206,665 lb., valued at Rs. 1,20,490; and the Madras to 4,162,854 lb., valued at Rs. 2,94,235). In the "Dry Salted Fish" trade Madras takes by far the most important position. Out of the total exports of 1906-7, Madras supplied fish of this class to the extent of 9,934,728 lb., valued at Rs. 10,44,465, and these went almost exclusively to Ceylon.

Coastwise Traffic.—But to attain a fairly comprehensive conception of the location and extent of the Indian fisheries, it is necessary to consult the returns of coasting trade. It is unfortunate that no particulars are published of the fish carried by rail and river, as these might have afforded some data upon which to judge of the transactions in the more interior tracts. So far as is known, there are no large fish-curing centres connected with the fresh-water fish and fishing, so that the coastwise traffic may be accepted as fairly representing the local trade. The coastwise transactions are recorded under two headings—"Dry Unsalted" and "Dry Salted." Under each the traffic has fluctuated considerably, but on the whole forward. During the under-mentioned years the "Dry Unsalted" has manifested a satisfactory expansion, *viz.*, Rs. 19,85,869 in 1899-1900; Rs. 29,30,971 in 1903-4; and Rs. 25,61,334 in 1905-6; while the "Dry Salted" have practically remained stationary—Rs. 7,87,774 in 1899-1900; Rs. 7,80,301 in 1903-4; and Rs. 7,50,975 in 1905-6. By far the most remarkable features are the immense traffic towards the town of Bombay in cheap fish, and the fairly large supplies drawn by Rangoon of highly priced fish. Thus, for example, in 1905-6 Bombay imported coastwise "Dry Unsalted Fish" to the extent of 15,040,751 lb., valued at Rs. 6,43,159, and Burma 7,219,489 lb., valued at Rs. 18,10,459. The Bombay town supply was procured from British ports within the Presidency (Rs. 2,92,757); from Kathiawar (Rs. 2,60,698); from Daman (Rs. 66,044); and from "Other Provinces" (Rs. 22,660). The Burma supply was drawn from Bengal (Rs. 5,03,765); Madras (Rs. 7,24,770); "Other Provinces" (Rs. 1,94,453); and from the British ports within the province of Burma itself (Rs. 3,86,946). Turning now to the subject of the coastwise traffic in "Dry Salted Fish," the total for 1903-4 came to Rs. 7,80,301, and in 1905-6 to Rs. 7,50,975. But by far the most remarkable aspect in this traffic may be said to be the circumstance that the exports are almost exclusively into Bombay, Madras and Burma, in equal proportions and from their own provincial ports into their chief towns.

Dry salted
Fish.

Location of Fisheries.—It may, in conclusion, be inferred, from these observations, that the fisheries of India are mainly along the west coast from Kathiawar to Travancore; that Burma is the least self-supporting of all the provinces and demands from external sources a superior, not an inferior quality of fish; and lastly that Bengal, while it takes very little share in the export traffic in fish, produces apparently enough for its own necessities, since it practically imports no fish either from foreign countries or from other Indian provinces.

a large quantity is imported from U.S.

Fennel.

Cooke, *Fl. Pres. Bomb.*, i., 572-3; Firminger, *Man. Gard. Ind.* (ed. Cameron), 166; UMBELLIFERÆ. The Fennel, *saunf*, *bari saunf*, *sonp*, *mauri*, *pan-muhori*, *bari-shopha*, *variari*, *badishep*, *badisopu*, *azpa*, *badyan*, *sohikire*, *shombu*, *pedda-jila-kurra*, *sa-meit*, *madhurikā*. A perennial which attains a height of 5 to 6 feet, commonly cultivated throughout India, at all altitudes up to 6,000 feet, and also found wild.

Cultivation.

This plant seems to be grown only in small patches, on homestead lands, as a cold-weather crop. Firminger informs us that it thrives well in Bengal, and where once grown will come up each cold season afterwards, from self-sown seed. The seeds should be sown in October on the plains, and in March and April on the hills. Of the United Provinces, Duthie and Fuller intimate that fennel is extensively cultivated during the cold season in garden patches. In Bombay, the chief localities are Khandesh and Gujarat, but it is also grown in the Deccan.

Chemistry.

Fennel fruit yields about 3 per cent. of volatile oil, which consists of *anethol* or *anise camphor* and variable proportions of a liquid isomeric with oil of turpentine. The oil is used in Europe in the manufacture of cordials and enters into the composition of fennel water, which is known in India as *muhori-ka-arak* or *arak bādian*. [*Cf. Thorpe, Dict. Appl. Chem.*, 1900, iii., 12; Schimmel & Co., *Semi-Ann. Rept.*, Oct.-Nov. 1897, 27-8; Oct.-Nov. 1902, 42-3.]

Medicine.

The fruits and oil are stimulant, aromatic and carminative, used largely as flavouring agents to medicines. The root is purgative and the leaves diuretic. [*Cf. Pharmacog. Ind.*, ii., 1890, 124-7; Dutt, *Mat. Med. Hind.*, 1900, 174; White and Humphrey, *Pharmacop.*, 1904, 203.]

Trade.

The exports are not very important. During the five years ending 1903-4 they ranged from 3,355 cwt., valued at Rs. 29,277, to 14,085 cwt., valued at Rs. 1,16,370, but have since declined to 10,974 cwt., valued at Rs. 1,09,735 in 1906-7. Ceylon is usually the most important receiving country, though during 1903-4 and 1904-5 the United Kingdom took the largest amounts, viz. 5,396 cwt. and 10,521 cwt., but in 1906-7 took only 522 cwt. Outside the British Empire, Germany is the only country that need be mentioned. In 1903-4 it took 1,424 cwt., and in 1906-7, 2,272 cwt. Practically the whole of the exports go from Bombay.

G. a bogla, *Desr.*; Talbot, *List Trees, etc.*, 1902, 27; *Cooke, Fl. Pres. Bomb.*, 1903, i., 77; *Brandis, Ind. Trees*, 51. The *hila*, *aradal*, *manthulli*, *po-puli*, *upagi mara*, *dharambe*, *ghorkepulli*, *gorakkapulli*, *goraka*, etc. A small evergreen tree of the western coast and Ceylon, ascending to 6,000 feet on the Nilgiris. It is said to yield a yellow, very adhesive GUM, which is valueless as a pigment because insoluble in water. It is, however, soluble in spirits of turpentine, and thus forms a beautiful yellow VARNISH. It also gives an OIL used in medicine. The FRUIT is edible and of a pleasant acid taste. It ripens during the rainy season. The rind of the fruit is employed as a condiment and eaten with fish as a substitute for tamarind. The WOOD is grey, sometimes patched with red, smooth and close-grained. Beddome remarks that it would be useful for common furniture. [*Madras Weekly Mail*, May 16, 1901.]

G. Cowa, *Roxb.*; *Rec. Bot. Surv. Ind.*, 1893-1902, i., 56; 1903, ii., 82; *Prain, Beng. Plants*, 1903, i., 247; *Firminger, Man. Gard. Ind.* (ed. Cameron), 1904, 289; *Brandis, Ind. Trees*, 52. A tall evergreen tree with a round stem. It occurs in Bengal, Assam, Chittagong, Burma and the Andaman Islands. In Bengal it is the *cowa*, and in Burma the *taungthale*, *ma-dow*. It produces

KOKAM BUTTER

GA CINIA
A GO TA A
Mangosteen

a yellow GUM which is insoluble in water, but with spirits of turpentine gives a beautiful and permanent yellow VARNISH for metallic surfaces. In certain districts the bark is employed to produce a light-yellow DYE used in colouring cloth for the garments of Buddhist monks. Duncan (*Dyes and Dyeing, Assam*, 1896, 25) mentions that its use in dyeing is unknown in that province. The FRUIT ripens at the beginning of June, and is of the size and form of a small orange. It is acid in taste, but otherwise good, and makes a very fine preserve. The WOOD is not used for any economic purpose.

G. heterandra, Wall. An evergreen tree of the hills of Burma up to 3,000 feet. It is the *thanattaw* or *tha-nat-tau*, and yields a superior quality of gamboge sometimes called Arakan. [*Cf. Hanbury Journ. Agri.-Hort. Soc. Ind. (Proc.)*, 1859, x., 121.] A sample from Tavoy, when analysed, gave:—resin 76.5 per cent.; gum 23.5. [*Gamble, l.c.* 55.]

Kokam
Butter.

This slender tree with its drooping branches is found in the forests of the Konkan, Kanara, Coorg and Wynaad, and is often planted, especially in the southern districts of the Bombay Presidency. It thrives particularly well on the lower slopes of the Nilgiris, and a writer in *Indian Gardening* (March 16, 1899, 108) recommends its cultivation for the fruit as a by-product on lower elevation estates. From the SEEDS of the fruit a valuable OIL is extracted known as *kokam* butter. It is obtained in one of several ways by boiling, churning, or simply pressing the seeds in an ordinary oil-mill. In the Indian bazárs it is found in the form of egg-shaped or oblong lumps, of a whitish colour, at ordinary temperatures, firm, dry and friable, yet greasy to the touch. Examination of the glycerine under the microscope proves it to be crystalline. Usually it contains a considerable amount of impurity, but by filtration it may be obtained perfectly pure, transparent, and of a light-yellow colour. It melts at 98° F. According to Flückiger and Hanbury it contains stearic, myristic and oleic acid. In medicine it is considered nutritive, demulcent, astringent and emollient. It is also used as a substitute for cod-liver oil, and in the preparation of ointments. The FRUIT, sometimes called the wild mangosteen, has long been considered an article of food. Garcia de Orta (1563) refers to it under the name of *brindols*, and in his note on Linschoten's account of Indian fruits Paludanus (1596) calls it *brindoijus* and speaks of its sour taste—it is called *brindao* in Goa to-day. Woodrow mentions that a statement made by Graham in the *Bombay Courier* (June 12, 1830), to the effect that it is used at Goa for adulterat' g *ghí*, had been denied by a writer in *The Indian Times*. At the present day the dried fruit is used as a condiment in curries, and in the preparation of acidulous drinks. A considerable trade in *kokam* butter is carried on by the Goanese. [*Cf. Pharmacog. Ind.*, 1890, i., 163-7; Moodeen Sheriff, *Mat. Med. Mad.*, 1891, 45-6; Andés, *Veg. Fats and Oils*, 1897, 216, 218; Waring, *Baz. Med. Ind.*, 1897, 83-4; Wright, *An. and Veg. Mangosteen, *mangústán*, *mustah*, *mengkop*, *mimbu*, *youngzalai*, *manggis*. An evergreen tree of the Malay Peninsula, indigenous to the Molucca Islands. [*Kew Bull.*, 1898, 26.] Fairly extensively cultivated in Burma (Tenasserim) and in a few special localities in India, such as the Barliár gardens, Nilgiri hills.

ango-
steen.

Though frequent efforts have been made in Bengal and Western India to grow this tree, it has not been known to fruit successfully. In Ceylon, Trinidad and Jamaica better results appear to have been attained. A warm moist, insular climate seems essential to success. In the open plains it does not thrive so well as in valleys with light shade. Is liable to the disease known as gamboge canker.

Pipe Gamboge.

It is propagated by seed, grafting or inlaying, and on rich loamy, well-drained soils. The tree is commonly said to begin to bear when from 7 to 10 years, or, according to other experience, not until it is 15 to 20 years old. It may continue to yield thereafter for 50 to 100 years. The fruiting season is June to September. Rich cultivation is essential, such as manure once a year. Care must also be taken in picking the fruit, since until the rind has hardened it is delicate—a fall may often be fatal to any idea of preservation. The yield has been variously stated. A writer in *Indian Gardening* speaks of trees planted 25 by 25 feet yielding 1,000 fruits an acre, with a net profit of £2. A writer in *The Planter*, on the other hand, affirms that each tree may give an annual income of £2 to £5. Gamble observes that according to Helfer one tree may yield 1,000 fruits yearly, valued at Rs. 3 per 100. At Barliár a tree has been reported to have given 1,200 fruits. The fruits are usually strung by a bast fibre, being tied between the thick, hard, calyx teeth and the fruit; bunches thus formed are hung up to mature. If intended to be transported, these bunches should be packed in baskets along with wet moss, and dispatched the day they are plucked. Some years ago a consignment of fresh fruits was sent to London from the West Indies, but apparently no trade has as yet been organised. As an article of food, the fruit is highly esteemed both by Europeans and Natives, and is considered by many persons the most delicious of Eastern fruits. Ships coming from the Straits bring it to Rangoon and Calcutta, but by the time they reach the latter port the fruits have lost their true flavour, and are often very bitter, through the formation of layers of yellow gamboge between the pips. A considerable trade is done, however, and the price ranges from Rs. 3 to as much as Rs. 10 a hundred, according to season and quality. Recently an attempt has been made to preserve the mangosteen, and a little more enterprise might make this an important industry. Traffic in mangosteen is, in fact, very ancient. Tavernier (*Travels Ind.*, 1676 (ed. Ball), ii., 287) speaks of the fruit as abounding in Siam.

The rind is a powerful tanning material, and an attempt has been made to utilise the immense quantities available in Burma and the Straits. [*Cf. Agri. Ledg.*, 1902, No. 1, 14.] The chemistry of the rind was investigated by Schmidt in 1855. It contains tannin, resin, and a yellow crystallisable principle, *mangostin*. In medicine the rind or entire fruit is employed in the production of a syrup that is used in chronic diarrhoea and dysentery. [*Cf. Pharmacog. Ind.*, i., 167; *Yearbook of Pharmacy*, 1892, 167; 1900, 399; *Settl. Repts. Amherst*, 1893, 47; *Cult. in Singapore, Agri. Bull. Straits*, 1902, i., 373; Nisbet, *Burma under Brit. Rule and Before*, 1901, i., 352; *Hawaiian For.*, 1905, ii., 91; *Trop. Agrist.*, 1905, xxv., 259-60.]

G. Morell, *Desr.*; Talbot, *List Trees, etc.*, 1902, 27; Cooke, *l.c.* 77-8; Gamble, *l.c.* 55; Brandis, *Ind. Trees*, 1906, 53. Indian Gamboge Tree. The vernacular names may be thus grouped:—the tree—*arsinagurgi mara*, *aradal*, *punar puli*, *kankutake*, *daramba*, *tha-men-gút*: the resin—*ghótághaubá*, *ausaraherevan*, *revachinnisirá*, *makkhi*, *ireval-chinip-pál*, *sanato-sí*, *rubbirevánd*, *farfiran*, etc. An evergreen tree of the forests of the Khasia hills, Eastern Bengal, the West Coast and Ceylon. The Gamboge of European commerce comes from Siam, and is obtained from *G. Hanburyi*, *Hook.*, f. (*Kew Mus. Guide*, 1907, 20).

From the GUM-RESIN is produced the gamboge of medicine and the arts. That substance has been known almost from classic times. Of European writers it was first mentioned apparently by Clusius (1605). It is referred to in Chinese works as far back as the end of the 13th century. The gum is not collected to any material extent in the forests of India, and the chief supply comes, therefore, from Siam. Before the resin can be gathered, the trees must be some ten years old. Tapping is carried on during the rainy months, June to October, when the sap is vigorous, by cutting a spiral line round the trunk from a height of about ten feet above the ground. Down these grooves the resin trickles in a viscous stream into hollow bamboos placed at the base. From these it is decanted into smaller bamboos, and left for a month or so to solidify. To remove the gamboge the bamboo joints are placed over a hot fire, which causes them to crack, when a round stick of gamboge is obtained from each—the Roll or Pipe Gamboge of commerce. This method does not seem to be employed in India, where only

THE GAMBOGE PLANT

G - T N
AJ

small incisions as a rule are made, and the resin collected in small tear-drops. In Ceylon it is procured by cutting here and there a thin slice off the bark and scraping away the resin which collects on the exposed surface. Cake and Granular Gamboge are thus obtained, but both these are less pure than Siam pipe gamboge. The best commercial samples of the pipe gamboge are of a rich brown colour externally, dense and brittle, with a conchoidal fracture of a reddish-yellow colour, odourless and tasteless at first, then acrid. Mixed with water it forms a yellow emulsion. Hurst (*Painters' Colours, Oils, etc.*, 1901, 461) gives an account of the chemistry. Analysis shows it to contain:—moisture, 2.50 per cent.; mineral matter, 1.05; resin soluble in ether, 66.05; wax soluble in alcohol, 4.31; gum, 26.03. Gamboge dissolves in ammonia with a yellow colour, and this solution produces yellow and red dyes with zinc, alumina, and lime mordants. The average London quotation for Siam gamboge varies from about £6 10s. to £10 per cwt.

G. Xanthochy us, Hook., *f.*; *Rec. Bot. Surv. Ind.*, i., 336; Talbot, *l.c.* 27-8; Cooke, *l.c.* 78; Prain, *Beng. Plants*, i., 247; Firminger, *l.c.* 290. The *dampel, tamál, tepor, manhola, tavor, iwara memadi, mukki, janagi, madaw*, etc. A medium-sized evergreen tree of E. Himalaya and E. Bengal; from Kanara south, through Coorg and the Nilgiris; also in the N. Circars, Burma and the Andaman Islands.

A large quantity of an inferior gamboge is obtained from the GUM-RESIN of this species. In Assam it is extensively used as a DYE. The Phakials of Lak-himpur also employ the bark to produce a bright yellow. The mordant used is the green leaves of *Symplocos grandiflora* (*bhomrati*). [*Cf.* Duncan, *Dyes and Dyeing, Assam*, 1896, 26.] The FRUIT is utilised in medicine either fresh or dried, and also eaten as a FOOD. It ripens in January and February, and is sometimes used in place of the tamarind for preparing curry, and this fruit, as also that of *G. paniculata*, are used in the preparation of vinegar (see p. 1109).

G - T N.—Holland, *Rev. Min. Prod. Ind.*, 1898-1903, in *Rec. Geol. Surv. Ind.*, 1905, xxxii., pt. i., 106-9; also *Imp. Gaz.*, 1907, iii., 160-3. Holland states that the most important of the precious and semi-precious stones of India are amber, jadeite and ruby. "The only precious and semi-precious stones at present mined in India are the diamond, ruby, sapphire, spinel, tourmaline, garnet, rock-crystal, and the various chalcedonic forms of silicon, jadeite and amber" (see p. 64). The Pearl, though not a mineral but an animal gem-stone, may be described here. In the present article, therefore, a classification into MAJOR and MINOR gems may be adopted advantageously. Under the heading of MAJOR GEMS will be taken up in alphabetical sequence—Beryl, Diamond, Pearl, Ruby, Sapphire, Spinel, Topaz and Turquoise; under MINOR GEMS—Garnet, Jade, Lapis Lazuli, the Quartzose minerals (Rock Crystal, Agate, Onyx, Jasper, etc.), and Tourmaline.

Gem-
stones.

Total Trade.—The value of the precious stones found annually in India does not apparently equal the value of the unset stones and pearls imported. The IMPORTS in 1903-4 amounted in value to Rs. 1,52,15,502, and in 1906-7 to Rs. 93,38,103, and came chiefly from the United Kingdom, Arabia, France and Persia. The share of Bengal was Rs. 94,62,278

I ports.

Exports.

in 1903-4, and Rs. 6,05,482 in 1906-7; of Bombay, Rs. 55,02,591 in 1903-4, and Rs. 84,49,271 in 1906-7. The balance on the totals of the years named went to Burma. In the same years the EXPORTS (Indian merchandise, including Jade) amounted to Rs. 9,25,257 and Rs. 18,81,608, and the re-exports to Rs. 92,118 and Rs. 2,57,598.

I. MAJOR GEMS.

Aqua-marine.

1. **eryl.**—Ball, *Man. Econ. Geol. Ind.*, 1881, iii., 520-2; Holland, *l.c.* 107-8. The *sabzá*, *panooa*, *fastiki kerasi*.

Prof. Church writes me that beryl includes not only the rich green emerald, but also the sea-green aquamarine as well as the white, and the bluish varieties of a mineral species, which is a silicate of alumina and another earth, now generally called beryllia.

According to Holland, the palest varieties are common in the granite pegmatites of India, but the crystals are too fissured for use as gem-stones. The only places where attempts have been made to excavate pegmatite solely for its aquamarines are at Padyur (Pattalai) near Kangayam, Coimbatore district, and at different places in the Toda hills in Rajputana. [*Cf. Linschoten, Voy. E. Ind.*, 1598 (ed. Hakl. Soc.), 1885, ii., 138; Tavernier, *Travels*, 1676 (ed. Ball), 1889, ii., 104; Milburn, *Or. Comm.*, 1813, ii., 288; Watt, *Min. Rev. Ind.*, 1894, 16; 1895, 39; 1896, 38; 1897, 36-7.]

iii., 92-101.
Diamond.

2. **Di ond.**—Ball, *Man. Econ. Geol. Ind.*, 1881, iii., 1-50; Tavernier, *Travels*, 1676 (ed. Ball), ii., 431-64; *Rec. Geol. Surv. Ind.*, 1889, xxii., pt. 1, 1-2; pt. 4, 282-3; 1890, xxiii., pt. 2, 69-72; pt. 3, 153-6; Holland, *l.c.* 108; also *Imp. Gaz.*, iii., 160-1; Watt, *Mem. Res. Ind.*, 1894, 23-4; *Min. Rev.*, 1894, 16-7; 1895, 39; 1896, 38-9; 1897, 37; *hírá*, *almás*, *híraka*, etc.

Sources.—India was the first and for long the only source of diamonds known to European nations, and most of the great historic diamonds, the Koh-i-nur, the Orloff, the Pitt, etc., were obtained from that country. Many of the early Indian explorations by Europeans were primarily conducted with a view to learn particulars of the supply of diamonds and other precious stones. References to Indian diamonds accordingly occur in the writings of most of the early travellers. Marco Polo wrote of them in the 13th century. Varthéma (*Travels*, 1510 (ed. Hakl. Soc.), 1863, 107) deals specially with the diamonds of Cambay. The history of the Koh-i-nur, given by Tavernier (1676, *l.c.* 123-7), traces that gem back to the time of the Emperor Baber (*Memoirs* (Leyden and Erskine, transl.), 308). Jahangir (*Memoirs* (Price, transl.), 2-3, 51) gives an account of the diamonds in the crown and throne used by him. Garcia de Orta, who was in India in 1563 (*Coll.*, xliii.; also in Ball, *Proc. Roy. Ir. Acad.* (3rd. ser.), 1890, i., 657-61) mentions various Eastern diamond mines, such as that of "Bisnager" (Vijayanagar) and the "Decam" (Deccan). Ball, in his translation of Tavernier's *Travels*, gives full particulars of all the Indian sources of diamonds, and the reader desirous of such details should, therefore, consult that work (app., 431-61). Tavernier—a diamond merchant—was the first European to critically examine the diamonds and the Court jewels of India. His work is, accordingly, highly instructive. Fryer (*New Acc. E. Ind. and Pers.*, 1675, 188, 212-4) and Thevenot (*Travels in Levant, Indostan*, etc., 1687, pt. iii., 98-100, 104) speak of the diamonds of Golconda, etc. (Golconda mines, consult Ball, *l.c.* 453-6). Milburn (*Or. Comm.*, 1813, ii., 79-81) furnishes particulars for the guidance of the purchaser and enumerates the more important historic diamonds that had been procured from India up to the beginning of the 19th century.

Production.

Three Groups.

The following account by Holland gives concisely the chief facts of the modern production:—"Notwithstanding the reputation (stretching back even as far as Ptolemy in the European, and further in the Hindu, classics) which India has had as a diamond-producing country, the output of to-day is very small and comparatively unimportant. The places which, according to accounts, have been most productive in the past form three great groups, each in association with the old unfossiliferous rocks of probably pre-Cambrian age, now known as the Purána group, and distinguished locally as the Cuddapah and Karnul systems in South India, and as the Vindhyan system in the northern

part of the Peninsula. The southern of the three groups of diamond-occurrences includes localities, with apparently authentic records, in the districts of Cuddapah, Bellary, Karnul, Kistna, and Godavari. Loose stones have been picked up on the surface of the ground, found in deposits of alluvium and in the workings which have been undertaken in the so-called Banaganpilly stage of the Karnul series of strata. In the second group of occurrences, in the Mahanadi valley, the stones have been found in the alluvium of the Sambalpur and Chanda districts, and though strata similar to those of the Vindhyan and Karnuls are known in this area, no diamonds have been found in these older rocks. The third group of occurrences occupies a tract some sixty miles long by ten miles wide, with the Vindhyan conglomerates near Panna as the centre. The diamond-mining industry still persists in this area, both in the old conglomerate of Vindhyan age, and in deposits which, though described as alluvium, are possibly relics of Lameta (Upper Cretaceous) deposits."

Southern.

Mahanadi.

Panna.

Industrial Uses.

Mechanical
Poison.

The diamond, on account of its hardness, has for long been made use of for glass-cutting purposes. A rude variety, known as Bort, has been chiefly employed in this way. In medicine, diamond dust is known to be a powerful mechanical poison. [Cf. Hedges, *Diary*, 1681-7, iii., cxxv., *et seq.*; Heyne, *Tracts on Ind.*, 1814, 92-107; Bernier, *Travels*, 1656-68, app., 469-71; King, *Ind. Agri.*, Nov. 1892; *Madras Weekly Mail*, Dec. 13, 1900, 562; The Pitt Diamond, confer Walter Fitz-Patrick, *Rept. Hist. MSS. Comm.*, 1892; Brough, *Mining of Non-Metall. Min.*, in *Journ. Soc. Arts*, Jan. 15, 1904, 168-72.]

3. Pearl, Pearl Fisheries and Mother-of-pearl.—Pearls are found in several molluscs which inhabit shallow seas and sandbanks in both the Old and New Worlds. The most productive is the so-called "Pearl Oyster," in reality a mussel—*Meleagrina margaritifera*, Lam. Modern classification, however, favours its reduction to *Avicula*; *moti*, *mutti*, *muthu*, etc.

D.E.P.,
vi., pt. i.,
117-22.
Pearls.

Formation.—It is now known that most pearls are formed by the presence of some foreign substance, which becomes embedded in the interstices of the molluscan mantle and constitutes a source of irritation. This irritation causes the mollusc to deposit nacreous matter in concentric layers until the foreign particle becomes completely encysted. It has been practically established, chiefly through the investigations of Dr. Lyster Jameson, that the irritating substance which induces the pearl-formation is very seldom a sand grain, but almost always a small parasite, in some cases a simple protozoan, in others one of the stages in the life history of a flat worm. Prof. Herdman of Liverpool, who was requested to examine the fisheries in the Gulf of Manar, states in his report that the majority of the best pearls contained as their nuclei the remains of certain Platyhelminthian parasites, which he identified as the larval condition of a Cestode or tape-worm. This cestode passes from the body of the pearl oyster into that of a file-fish and from the file-fish into some larger animal, possibly the large Trygon or ray.

Parasitic
Action.

Though pearls originate in the mantle, they nevertheless, when large, frequently work their way out and lie loose between it and the shell, or become attached by subsequent nacreous deposit to the "mother-of-pearl" surface of the latter. In this position a pearl may become so covered up as to form a hemispherical mass which when cut out forms the "perle bouton" of the jewellers. The hollow warty pearl, known as "blister pearl," is produced by a deposit of nacre in order to close an aperture arising from some injury.

Formation.

Blister Pearls.

Indian Fisheries.—The pearl fisheries of India have been famous from remote times. Garcia de Orta in 1563 (*Coll.*, xxxv.) mentions the principal localities in the Persian Gulf where pearls were then obtained and says the pearls were cleaned and polished with pounded rice and salt. Linschoten in 1598 and Tavernier in 1676 describe both the Persian and the Ceylon pearl fisheries. At the present time the largest pearl fisheries in the East are those of Ceylon, for information concerning which the reader should consult the reports submitted to the Government of Ceylon in 1904 by Prof. Herdman, Mr. J. P. Lewis and Mr. Hornell; also Herdman's much fuller report published by the Royal Society (London, 1903-6, 5 vols.). In 1905 the total amount realised was Rs. 25,10,621, and the number of oysters fished up 49,250,189. These fisheries (it is understood) have been recently sold, or rather leased, for £20,000 a year to a company who are to work them. The only other pearl fishery of importance

earl.

is that of the Mergui district, Burma, which forms a considerable source of revenue to the Burma Government.

MOTHER-OF-PEARL (see p. 989) is procured in connection with the Pearl and Chank fisheries of South India. It is carried all over the country, but curiously enough is not worked up to the extent that might be anticipated, though a fairly large trade exists in exporting the shells (Watt, *Ind. Art at Delhi*, 1903, 206-8).

[Cf. Renaudot, *Acc. Ind. and China by Moham. Trav.* in 9th century (Engl. transl.), 1733, 95-8; Marco Polo, *Travels* (ed. Yule), 1871, ii., 267, 274, etc.; Barbosa, *Coasts E. Ruby.

4. **uby**.—Ball, *Man. Econ. Geol. Ind.*, iii., 427, etc; Fritz Noetling, *Note on Rept. Namseka Ruby Mine, Mainglon State*, in *Rec. Geol. Surv. Ind.*, 1891, xxiv., pt. 2; Holland, *Rev. Min. Prod. Ind.*, vi., 584-9; also *Imp. Gaz.*, iii., 161. The *lal*, *manak*, *kembu*, *yákut remáni*, etc.

Oriental.

This name is applied by lapidaries and jewellers to two distinct minerals, the True or Oriental Ruby and the Spinel-ruby (see opposite). The former is a clear, crystalline form of alumina, coloured by some metallic oxide, chiefly that of chromium or of iron, while the latter is an aluminite of magnesium. In hardness the true ruby is inferior only to the diamond, a fact which affords the simplest test for distinguishing it from spinel, but it is also denser and dichroic.

Burma.

Sources.—Rubies have been found in certain localities in Southern India, Ceylon, Afghanistan and Badakhshan, but the chief sources both of the Oriental and the spinel ruby are in the mines of Upper Burma. Garcia de Orta (1563, *Coll.*, xlv., also in Ball, *Proc. Roy. Ir. Acad.* (3rd ser.), 1889-91, i., 665) gives some account of rubies, but remarks that under the name of "ruby" a great many stones are placed. Ball, commenting on Garcia, says that definite information of the occurrence of true rubies in India, at least the existence at any time of regular mines, is wanting. Tavernier makes numerous references to the ruby, and Ball in his edition of that work (1889, ii. (app. v.), 465-70) takes the opportunity to give a full account of the ruby mines of Upper Burma which should be consulted by the reader.

Early Records.

Mining.

Mining.—At the present day ruby mining in India is confined to the province of Burma, the most important locality being near Mogok. Here the rubies occur in a clayey mass, an alteration product of a coarsely granular marble. According to Mr. Bennet Brough, the methods of mining in Burma are suited to the three conditions of its occurrence, in the limestone, in hill detrital material, and in the alluvial deposits in the valleys. The following account is taken from Holland. "During the period under review the ruby-mining industry in Upper Burma underwent a new and favourable phase, the mineral having become, next to petroleum, the most profitable source of revenue among the Burmese minerals. Various leases were granted in the ruby-bearing area near Nanyaseik in the Myitkyina district, and in the 'stone-tract' of the Sagyin hills, in Mandalay district, and the results have been most profitless; but the returns for the Mogok area, where the Burma Ruby Mines Company is paramount, show that the industry has entered a most encouraging phase. The Company was granted the right in 1889 to mine for rubies and to levy royalties from persons working by Native methods, the lease being renewed in 1896 for fourteen years, at a rent of Rs. 3,15,000 a year plus a share of the profits. The result being, however, unsatisfactory from the shareholders' point of view, the rent was reduced in 1898 to Rs. 2,00,000, the share of the profits being at the same time raised from 20 to 30 per cent. A dividend of 5 per cent. was paid for the first time in 1898, when the value of rubies obtained amounted to £57,950. In 1899 the Company obtained rubies to the value of £90,848, and paid a dividend of 12½ per cent.; in this year three unusually valuable stones were found, one of 77 carats

Concession.

being valued at 4 lakhs of rupees (£26,666). In the following year (1900) the value of the stones raised increased to £97,326, and the Company paid a dividend of 17½ per cent. The year 1901 showed the record output of stones, valued at £104,476, whilst in 1902 they brought £86,895. In the last year (1903) the Company's receipts were £98,575, and profits on the year's working £44,950."

apphire.

Sources.—The sapphire is a transparent variety of corundum or native alumina, composed of oxide of alumina with traces of other substances to which its colour is due. The colour varies from the palest blue to deep indigo, while violet, yellow and green varieties are also met with. Both dark and light varieties are described by Garcia de Orta (1563, *Coll.*, xlv.), who says the latter are called *safira de agua* (water sapphire) and that both varieties are found in "Calicut, Cananor and in many parts of the kingdom of Bismager." Ball (Rev. of Garcia de Orta, in *Proc. Roy. Ir. Acad.*, 1889-91 (3rd ser.), i., 664), commenting on this subject, states that he has no definite information as to the former workings of sapphire deposits in India. In recent years the chief source of sapphire was at Zanskar in Kashmir, but the mines are now said to be exhausted. According to Holland (*l.c.* 109), the normal blue sapphire and rarer green, yellow and white varieties are occasionally found in the ruby-bearing gravels of Burma. [Cf. Tavernier, *Travels*, 1676 (ed. Ball), 1889, ii., 102, 465, 470; Thevenot, *l.c.* 99; Lawrence, *Valley of Kashmir*, 1895, 60-1; *Min. Rev. Ind.*, 1895, 41; 1896, 40; 1897, 40; Bennet Brough, *l.c.* Jan. 14, 1904, 172.]

Composition.

Kashmir.

6. **i el.**—Ball, *l.c.* 429-31; Holland, *l.c.* 109.

pinel.

The spinel or Balas ruby differs from the true Oriental ruby by containing a considerable percentage of magnesia with traces of chromium and iron oxide. In hardness it is also inferior to the true ruby, of which it is a constant associate and for which it is frequently mistaken. [Cf. Tavernier, *l.c.* ii., 102, 467.]

Turquoise.

The existence of the true turquoise in India is doubtful. Holland remarks that its only importance lies in the fact that India is one of the channels by which the material procured in Persia and adjoining areas reaches the European and Eastern markets. The art of manufacturing and colouring imitation turquoise has become a science with the traders in these stones. Recently a new industry has arisen in Kashmir in ornamenting metal wares with a layer of false turquoise embedded over the surface (Watt, *Ind. Art. at Delhi*, 1903, 50, 75). [Cf. Linschoten, *l.c.* ii., 141; Tavernier, *l.c.* ii., 103; Milburn, *Or. Comm.*, 1813, ii., 543; Bennet Brough, *Mining Non-Metall. Min.*, in *Journ. Soc. Arts*, Jan. 14, 1904, 174.]

II. MINOR GEMS.

9. **G r et.**—Ball, *Man. Econ. Geol. Ind.*, 1881, iii., 521-4; Holland, *Orig. and Growth of Garnets, etc.*, in *Rec. Geol. Surv. Ind.*, 1896, xxix., pt. i.,

arnet.

GEM-STONES

Jade and Jadeite

20-30; also *Rev. Min. Prod. Ind.*, 1905, xxxii., pt. i., 108-9. The *yáqút*, *chunri*, *mehtab*.

Composition.

Garnets are silicates of alumina, iron, lime, magnesia or similar bases. They may be grouped in six sections as alumina-lime, alumina-magnesia, alumina-iron, alumina-manganese, iron-lime and lime-chrome garnets.

Supply.

Sources.—The garnet is common in various localities in India, those of Rajputana being the most important. Some stones from Rajputana are said to measure a quarter of an inch to six inches in diameter, and are reputed to be the best in the world. In the Madras Presidency they occur in Vizagapatam, Godavari, Trichinopoly and Tinnevely, and are fairly abundant in Burma. According to Holland, "The only garnets worked to any considerable extent in India occur in the mica schists of Rajmahal in Jaipur, and near Sarwar in the adjoining State of Kishengarh. Returns are not available to show the condition of the industry in Jaipur, but there is still a considerable industry in the Kishengarh State, though the yearly estimates are altogether too variable to permit of a fair average being drawn, varying from about £10,000 to £2,000."

Jaipur Jewellery.

Cut garnets in the form of necklaces and other small articles of personal adornment constitute an important section of the lapidary craft of India (Watt, *Ind. Art at Delhi*, 1903, 74-5). The chief centre of the production of these goods is Jaipur. The qualities known are the so-called amethystine or Oriental garnets, which are usually cut in the form of pendants for jewellery, and the more valuable noble or almandine garnets.

Oriental Garnets.

[*Cf. Garcia de Orta*, 1563, *Coll.*, xlv.; *Milburn, l.c. ii.*, 288; *Min. Prod. Ind. Rev. and Agri. Dept.*, 1892, 3; *Min. Rev.*, 1894, 17; 1895, 39-40; 1896, 39; 1897, 37-8; *Introd. Jade,
Jadeite,
Jadestone.

10. **J de d J deite**.—Ball, *Man. Econ. Geol. Ind.*, 1881, iii., 516-8; Fritz Noetling, *Rept. Econ. Res. of Amber and Jade Mines Area, Upper Burma*, in *Rec. Geol. Surv. Ind.*, 1892, xxv., pt. iii.; *Occurrence in Upper Burma*, 1893, xxvi., pt. i., 26-30; Baner, *Jadeite from Tammaw, Upper Burma*, 1895, xxviii., pt. iii., 91-5; Holland, *l.c.* 52-4. The *yashm*, *sang-i-yashab*, *sútashi*, etc. Under the name JADE several different minerals are included, not always easily distinguishable. True jade or nephrite is a native silicate of calcium and magnesium, and may be regarded as a crypto-crystalline variety of hornblende. JADEITE, commonly confused with true jade, is a silicate of soda and alumina, is harder and has a higher specific gravity and greater fusibility than jade. Both jade and jadeite are of economic importance and are comprised under the general term JADESTONE.

Burma.

Sources.—The chief source of the mineral is in Upper Burma. According to Holland, some of the best material is obtained as pebbles in the gravels of the Uru river, a tributary of the Chindwin, but most is obtained by quarrying near Tammaw, in the Mogaung Sub-Division of the Myitkyina district. The jadeite here is enclosed in an eruptive rock closely resembling serpentine which pierces strata probably of Upper Miocene age. No jade (nephrite) of the kind which would be regarded as a marketable mineral is known in India, though a mineral having the essential composition and approaching jade in physical characters is known in South Mirzapur. Outside India it may be remarked that in South Turkestan true jade has been worked for many centuries.

Mining.—The method of extraction is very primitive. Before the discovery of the Tammaw mines, the mineral was obtained only in the form of boulders in the Uru valley, mixed with other rocks in the alluvial deposits of the river. "The boulders are obtained either by digging holes along the bank of the stream or by diving to its bottom. The boulders brought to the surface are at once broken, and the jadeite separated from the useless stuff" (Noetling). In the Tammaw mines the method employed is to heat the surface of the rock by large fires, the fall of temperature by night being sufficient to crack the rock. Crow-bars are then inserted in the cracks and the big blocks thus obtained are broken by mallets into lumps of convenient size.

Manufactures.—Jade is highly valued by the Chinese, and also by certain classes in India. The best is of an intense bright-green colour, but red and pale pinkish varieties are also prized. In Burma it is employed chiefly in the manu-

facture of finger- and ear-rings, bracelets, chains, etc. The chief seat of the manufacture of these articles is at Momein. All sort of cups, vessels, tables and other ornaments are made of it. [Cf. Watt, *Ind. Art at Delhi*, 1903, 73, 476-7.] Articles of spurious jade are also frequently met with. The most common of those in India is the Afghan jade-like serpentine, largely used in Bhera (Shahpur district) for making hafts of *peshquabz* (Afghan knives) and of hunting- or ordinary table-knives, small boxes, etc.

Trade.—In Upper Burma the export trade in jade-stone is very considerable. Some passes into South-West China by the overland route, but most finds its way down to Rangoon, whence it is exported to the Straits Settlements and China. During the six years 1897-1903 the exports averaged 3,911 cwt., valued at £44,770, giving an average value per cwt. of £11.45. The exports in 1906-7, according to the Official returns, were 2,998 cwt., valued at Rs. 8,02,270. [Cf. Warry, *Rept. on Jade Mines at Mogauing*, 1888; *Min. Rev.*, 1894, 17; 1895, 40; 1896, 39; 1897, 38; Lawrence, *Valley of Kashmir*, 1895, 65; Scott, *Gaz. Upper Burma and Shan States*, 1900, ii., pt. i., 277-89; 1901, ii., pt. ii., 268; Bennet Brough, *l.c.* 176.]

11. **L pis L zuli.**—Ball, *l.c.* 528-30. The *lajward*, *rajavaral*.

A mineral of complex composition, but consisting chiefly of silica, alumina and lime. It is commonly known as ultramarine from its blue colour. The mineral powdered was largely used in India for house decoration and book-illumination. [Cf. *Paulus Aegineta* (Adams, transl.), iii., 200-1; Linschoten, *l.c.* ii., 144; Tavernier, *Travels*, 1676 (ed. Ball), 1889, ii., 156; Milburn, *Or. Comm.*, 1813, i., 138.]

D. P.,

Lapis
Lazuli.

12. **Qu rtzose iner ls.**—Quartz is the natural silicic anhydride, but hydrated silica also exists. This has led to the classification of the stones of this kind into :—crystallised or phanero-crystalline anhydrous quartz, represented by the rock-crystals; uncrystallised or crypto-crystalline anhydrous quartz, including chalcedony, jasper, agate, etc; uncrystallised hydrated quartz. The opal is a type of this last group.

(a) **ock-crystal.**—Ball, *l.c.* 502-3; Holland, *l.c.* 107. The *bilaur*, *phatak*, *tansala*.

Sources.—Rock-crystal is the name given to the transparent varieties of crystallised quartz, the different colours which are met with being due to the presence of small quantities of foreign minerals. These coloured varieties are known by various names, e.g. Amethyst, Cairngorm, Rose-quartz, Smoky-quartz, Milk-quartz, etc., and Holland makes the following statement regarding the occurrence of this gem and its use in India :—“ In the Tanjore district, Madras Presidency, fragments of rock-crystal are collected and cut for cheap jewellery, being known as “ Vallum diamonds,” whilst the bi-pyramidal quartz-crystals found in the gypsum of the salt marl near Kalabagh, on the Indus, are to a certain extent used for making necklaces, and rock-crystal is similarly used for cheap jewellery in Kashmir.” In *Indian Art at Delhi*, 1903 (*l.c.* 75), it is stated that rock-crystals are also largely cut and made into sword and dagger handles, beads, buckles, necklaces, etc. These are turned out fairly extensively in Jaipur. The so-called “ rock-crystal ” buckles, etc., of Kashmir are very largely made of paste diamonds. [Cf. Mandelslo, *Travels*, in Olearius, *Hist. Muscovy*, etc., 1662, 83; Tavernier, *l.c.* i., 389; Milburn, *Or. Comm.*, 1813, i., 360-1; *Min. Prod. Ind. Rev. and Agri. Dept.*, 1892, 3; Watt, *Rev. Min. Prod. Ind.*, 1894, 18; Nicholson, *Man. of Coimbatore Dist.*, 1898, ii., 150.]

(b) **A ate and Carnelian.**—Ball, *l.c.* 503-4; Watt, *Ind. Art.*, *l.c.* 73-5; Holland, *l.c.* 107; *yamni*, *manka*, etc.

Agates are concretionary masses or nodules, which occur usually in hollows or veins volcanic rocks. When cut across, the sections show layers. Their composition consists of 70 to 96 per cent. of silica, with varying proportions of alumina, coloured by oxide of iron or manganese. Various varieties are found, known as Mocha stones, Moss Agates, Bloodstones, Chrysoprase, etc.

Sources.—According to Holland, a considerable trade in agate and the related forms of silica, called *hahik*, still exists. These are obtained from the amygdaloidal flows of the Deccan Trap, chiefly from the State of Rajpipla, where the main source is a conglomerate near the village of Ratanpur. Here the right to collect *hahik* is leased for a period of five years at annual rental. The ost

important place at which agates are cut is Cambay, but a certain amount of agate-cutting is also carried on at Jabbalpur, and other places within range of the Deccan Trap. They are much used for ornamental and decorative purposes, being made into brooches, rings, seals, cups, etc. The ancient *murrhine* vases, famous from the time of Pliny, are supposed to have been made of agates from Broach and Cambay. While collecting the pebbles the miners divide them into two primary classes—those that are not improved in colour by burning, and those that are. Of the former there are three chief varieties:—(1) the Onyx, known as *mora* or *bāwa ghorī*; (2) the Cat's-eye, *cheshamadār* or *dola*; and (3) a yellow half-clear pebble called *rorī* or *lasanīa*. All other stones are baked to bring out their colour. During the hot season, generally in March and April, the stones are spread in the sun in an open field. Then in May, a trench, two feet deep by three wide, is dug round the field. The pebbles are gathered into earthen pots, which, with their mouths down and a hole broken in their bottoms, are set in a row in the trench. Round the pots, goat or cow-dung cakes are piled, and the whole kept burning from sunset to sunrise. The pots are then taken out, the stones examined, and the good ones stowed in bags. About the end of May the bags are carried to the Nerbudda and floated to Broach. Here they are shipped in large vessels for Cambay, and offered for sale to the Carnelian dealers.

By exposure to the sun and fire, among browns the light shades brighten into white, and the darker deepen into chestnut. Of yellows, maize gains a rosy tint, orange is intensified into red, and an intermediate shade of yellow becomes pinkish purple. Pebbles in which cloudy browns and yellows were at first mixed are now marked by clear bands of white and red. The hue of the red carnelian varies from the palest flesh to the deepest blood red. The best are of a deep, clear, and even red colour, free from cracks, flaws or veins. The larger and thicker the stone, the more it is esteemed. White carnelians are scarce. When large, thick, even coloured, and free from flaws, they are valuable; yellow and variegated stones are worth little. It may be of interest to add in this connection that the burning of agates at Cambay is fully described by Barbosa at the beginning of the 16th century, so that it would appear to be a fairly ancient industry. And moreover other writers of an even earlier date allude to the agates of India without specially indicating their production.

[Cf. Varthéma, *Travels*, 1510 (ed. Hakl. Soc.), 107; Barbosa, *Coasts E. Africa and Malabar* (ed. Hakl. Soc.), 1517, 66–7; Mandelslo, *l.c.* 1662, 26, 40, 83; Tavernier, *l.c.* i., 69; Milburn, *l.c.* ii., 497–9; Paulus Aegineta (Adams Comment.), 1847, iii., 476; Campbell, *Bomb. Gaz.*, iii., iv., vii. and xxiii.; Watt, *Rev. Min. Prod. Ind.*, 1894, 17; *Ind. Art at Delhi*, 1903, 73–4.]

Onyx.

(c) *nyx*.—Ball, *l.c.* 503.

The onyx is the general term for those varieties of agate in which the colours are arranged in flat horizontal planes. It is reported to be plentiful in the crystal pits in the Betul district, and to occur near Amerwara in Chhindwara. It was formerly in great repute for cameos, and is employed for various articles of adornment. [Cf. Milburn, *l.c.* ii., 515; Watt, *Rev. Min. Prod.*, *l.c.*]

Jasper.

(d) *Jasper*.—Ball, *l.c.* 503–14; *Rec. Geol. Surv. Ind.*, 1895, xxv., 202.

A quartzose mineral, commonly of a red or yellow colour. The former occurs among the Cambay stones from the Deccan, and the latter in Tenasserim. A green variety is found in Burma, and fine specimens of ribbon jasper are met with in the Sandur hills, Bellary. [Cf. Garcia de Orta, 1563, *Coll.*, xlii.]

Opal.

(e) *pal*.—The *dhūdiā pathar*.

Compact uncrystalline semi-transparent to opaque hydrated silica. There are various varieties, of which the most valued is the Noble Opal, of a milky white colour, opalescent and exhibiting a rich play of colour. [Cf. Milburn, *l.c.* ii., 515; Bennet Brough, *Mining Non-Metall. Min.*, in *Journ. Soc. Arts.*, Jan. 15, 1904, 174.]

Cat's-eye.

(f) *Cat's-eye*.—The *chush-maidar*, *lasniyān* or *lahsaniya*.

A variety of chalcedonic quartz, presenting a peculiar opalescent reflection, said to be due to the presence of asbestos. It is called Cat's-eye from its resemblance to the eye of a cat, hence also the Burmese name *kyoung*, which has that meaning. [Cf. Garcia de Orta, 1563, *Coll.*, xlii.; L'choten, *Voy. E. Ind.*, 1598 (ed. Hakl. Soc.), 1885, ii., 141; Milburn, *l.c.* i., 361.]

Tourma-
line.

13. **T r l i e**.—Noetling, *Tourmaline Mines in Mainglon State*, in *Rec. Geol. Surv. Ind.*, 1891, xxiv., pt. ii., 125–8; Holland, *Rev. Min. Prod. Ind.*, 1905, xxxii., pt. i., 109.

A mineral of very complex and variable composition occurring in the granitic and metamorphic rocks of most countries. It is generally black, when it is termed *schorl*; red varieties (*rubellite*), dark-blue (*indicolite*) and white (*achroite*) also occur. The red variety is commonest in India, good specimens being of a deep crimson colour. White specimens have occasionally been found among the black stones from the Shan States, and green tourmaline has been mentioned as occurring in the Hazaribagh district of Bengal and in granite dykes in the bed of the Kauveri, Seringapatam. Holland states that various attempts have been made to work the red variety which occurs in the Ruby district of Upper Burma. In 1898 an outturn worth £359 was reported, in 1900 worth £1,240, and in 1903, £196, but returns for 1898 and 1902 are not available. [Cf. Milburn, *l.c.* i., 361-2; *Introd. Chem. and Phy. Study Ind. Min.*, 1859, 82; *Min. Rev.*, 1895, 42; 1897, 40; Scott, *Gaz. Upper Burma and Shan States*, 1900, ii., pt. i., 227-30; 1901, pt. ii., 392.]

For s of
Tourmaline.

GLA AND GLA WARE.—Glass is known in India by the vernacular names of *kanch*, *kunnadi*, *addannu*, *shishah*, *kizaz*. It is a mixture of silicate of potassium or sodium, or of both, with one or more silicates insoluble in water, such as those of the alkaline earths, aluminium, manganese, iron or lead. The mixture is effected by fusion.

D. P.,
iii., 503-5.
Glass.

History.—Stein (*Ancient Khotan*, 1907, 373), in discussing fragments of glass picked up at Niya (3rd century), observes, "Glass was until the middle of the fifth century of our era known in China only as an import from Ta-Ch'in, the Far West (Hirth, *China and the Roman Orient*, 228 *et seq.*), and it appears very improbable that the introduction of glass manufacture could have been delayed so long, if the making of glass had been an art practised in Eastern Turkestan when the latter was under Chinese control during earlier centuries. It is significant that, according to the *Pei shih*, the first makers of glass in China were traders from the country of the Great Yulchih, *i.e.* from the Old Indo-Scythian dominion, for whom the land route through Khotan was a more likely line of communication than the sea route."

Early
Knowledge.

In India glass is little employed for the purposes it is ordinarily used in other countries (windows, bottles, etc.), and the process of manufacture, as carried on by the Natives, is accordingly very crude and unscientific. The chief materials employed are carbonate of soda in its crude condition, called *reh*, and the impure sands of the rivers with certain special earths, etc. The ordinary Native glass is a coarse, impure, coloured or dirty mass, full of flaws and air bubbles, and suitable only for the manufacture of beads, coarse bangles and other minor articles. White glass is sometimes made (or rather re-made) by melting broken glass or glassware of European manufacture.

Indian Glass.

Indian Production.—The chief centres of the glass industry to-day are the Lahore, Karnal, Jhelam and Hoshiarpur districts of the Panjáb; the Bijnor, Lucknow and Saharanpur districts, United Provinces; Ahmednagar, Kaira and Baroda, Bombay; Seoni, Central Provinces; Patna, Bengal; lastly the State of Jaipur and the North Arcot district, Madras. The chief articles manufactured are bangles (*churis*), beads, crude globes, silvered with mercury or tinfoil, coarse toys, small bottles, lamp chimneys, etc. The only glassware in India with any pretension to art is that produced at Patna. The articles are generally coloured and the shapes very elegant but exceedingly fragile. The industry is said to be dying out for want of demand. Special mention may be made of the glass mosaics seen in the palaces of some parts of Rajputana, the Panjáb and Benares. It was to meet this demand that the industry of blowing glass globes, silvered inside, sprang into existence. The globes are broken up into fragments of certain sizes, then set in cement (or in Burma in lacquer), and in that way constitute the chief decorative feature of *shish mahals* (looking-glass palaces). The smaller fragments of silvered glass are also worked up into the embroidered *phulkari* cloths of the Panjáb. There is in addition the true mosaic art where coloured glass elaborates a pattern, seen in the palaces of Udaipur.

Bangles.
Beads.
Patna
Glassware.

The influences that operate against the establishment in India of glass works on a commercial scale are the cheapness of the imported Western products, the want of enterprise on the part of capitalists, and the unfavourable climatic conditions. Recently several praiseworthy efforts to extend the manufacture of

Gl Works.

glass on a scientific basis have been made; of one of the last, an account is given in *The Times of India* (Oct. 22, 1903). The greatest difficulty is perhaps the apparent absence of a suitable sand for fusing purposes, within easy reach of the trade centres, and of the fuel and other essential materials.

Trade.

Trade in Glass.—The total IMPORTS into India of glass and glassware of all kinds, including Government stores, were in 1876-7 valued at Rs. 29,45,091; twenty years later (1896-7) they stood at Rs. 72,25,918. For the five years ending 1906-7 they were as follows:—1902-3, Rs. 96,15,634; 1903-4, Rs. 1,01,17,065; 1904-5, Rs. 1,14,21,397; 1905-6, Rs. 1,14,79,658; and 1906-7, Rs. 1,22,75,725. The analysis of the commercial returns (1905-6) might be given as follows:—13,769,052 superficial feet of sheet and plate glass, valued at Rs. 12,44,884; 22,520 cwt. of beads and false pearls, valued at Rs. 24,02,442; 65,785 cwt. of bottles, valued at Rs. 6,50,645; bangles, Rs. 42,78,558; lamp-ware, Rs. 6,94,138; other miscellaneous glassware, Rs. 28,43,441; Government stores, Rs. 1,61,677. The sheet and plate glass came chiefly from Belgium and the United Kingdom; the beads from Italy, Austria, Germany and the United Kingdom; the bottles from the United Kingdom and Germany; bangles from Austria-Hungary; lamp-ware from Germany, Austria-Hungary and the United Kingdom; and the other wares from Austria-Hungary, the United Kingdom, Belgium and Germany. Bangles and lamp-ware were returned for the first time in 1905-6. In the same year the EXPORTS (Indian produce) amounted to Rs. 98,029. Bombay exported the largest amount, viz. Rs. 89,177, and the chief market was Persia, followed by Turkey-in-Asia, Arabia, Ceylon, Aden and the United Kingdom.

Crops*, 1893, pt. iii., 3, t. 85; LEGUMINOSÆ. (Following the suggestion made by Prain, the above name had better be adopted for the cultivated plant and *G. ussuriensis*, *Regel & Maack*, for the wild, which = *G. Soja*, *Sieb. & Lucc.*). The Soy Bean; in Indian vernaculars, *bhat*, *ram*, *gari-kulay*, *hendedisom horec*, *pond disom*, *an-ing-kiyo*, *tsu-dza*, *bhatnas*, *seta*, *musa*, *khajuwa*, etc.

A sub-erect or creeping annual native of China, Cochin-China, Japan and Java, comparatively recently introduced into India, though recorded as acclimatised and even seen as an escape from cultivation. It might, in fact, be described as extensively cultivated, though more as a garden than a field crop; is especially prevalent in Eastern Bengal, Assam (Barpeta Sub-division), the Khasia hills, Manipur, the Naga hills and Burma. It is not infrequent in the plains of India proper, especially in Busti, Gorakhpur, Patna and Purnea, etc. In Bombay and Madras, however, the Soy Bean has apparently hardly passed the experimental stage.

Cultiva-
tion.

Cultivation.—Two chief varieties occur, one called white, the other black. On the plains it is generally grown by itself as a *kharif* (autumn) crop. The seeds are sown from June to September, and harvested from November to December. They should be placed at a depth not exceeding 1 to 1½ inches, and 18 plants

THE SOY BEAN

G L
Occurrence

may be left, after weeding, to the square yard. A peaty soil, or one rich in organic matter, is preferred. A good manure for it is sulphate of potash, but nitrogen may be supplied with advantage in the form of nitrate of soda, or in the case of soils poor in organic matter, in the form of rape or mustard cake. In Assam it is sown with *ahu* (autumn rice) in April and May. The *ahu* crop is removed in July and August, and its stubble acts as a support for the bean plants, which are ready for harvest in December and January.

Seasons.

Church (*Food-Grains of Ind.*, 1885, 140-3) gives the following analysis of the bean:—in 100 parts: water 11.0, albuminoids 35.3, starch and sugar 26.0, fat 18.9, fibre 4.2, and ash 4.6. Its chemical composition thus places it above other pulses as an albuminous food. It is eaten in India in the localities where it is cultivated, chiefly in the form of *dál* or *satú*. In Japan it is largely used as a sauce, cheese (*natto*) or paste, and in China an edible oil is obtained from the seed. If cut when the pods are fully formed it makes a most nutritious fodder, and the seed-cake, as already stated, is an extremely rich cattle food. [*Cf.* Milburn, *Or. Comm.*, 1813, ii., 519; *Drug. Bull.*, Feb. 1890, 113; *Trop. Agrist.*, 1893, xiii., 50; 1903, xxiii., 175; King, *Trop. Agrist.*, 1897, xvii., 460; *Ind. Agri.*, March 1, 1899, 93; *Ind. Gard.*, Feb. 9, 1899, 56; *Agri. Food.

Fodder.

G LD.—Ball, *Man. Econ. Geol. Ind.*, 1881, iii., 173-230, 608-10; Mallet, *Man. Geol. Ind.*, 1887, iv., 1; Smith, *Gold Mining in India*, in *Mining Institute*, 1893; Watt, *Min. Rev.*, 1894 to 1897; also *Mem. Res. Br. Ind.*, 1894, 19-20; Bosworth-Smith, *Rept. Kolar Gold-Field and its Southern Extension*, 1889; Grundy, *Repts. Insp. Gold Mines, Mysore State*, 1894, 1895; Hatch, *The Kolar Gold-Field, Quartz-Mining and Gold-Recovery*, in *Mem. Geol. Surv. Ind.*, 1901, 1-90 (numerous plates); Holland, *Rev. Min. Prod.*, in *Rec. Geol. Surv. Ind.*, 1905, xxxii., pt. i., 10, 12, 45-50. Gold has been known since the most remote classic times of India; it is indicated by the following vernaculars:—*sona*, *gser*, *swarna*, *pwon*, *bungárum*, *mas*, *kanchana*, *shwae*, *run*, *tibr*, *zahab*, *tilla*, *zir*, etc.

D. P.,
iii., 519-33.
Gold.

Occurrence.—Gold is known to occur throughout India—in the Bengal, Madras and Bombay Presidencies; in the Central Provinces, Panjáb, United Provinces, Burma and many of the Native States. The ultimate derivation is mainly the quartz reefs which traverse the metamorphic and sub-metamorphic series of rocks, but smaller quantities appear to exist in certain chloritic schists and quartzites and possibly also in some forms of gneiss. The only other sources in Peninsular India are the recent and sub-recent alluvial deposits which rest on the metamorphic and sub-metamorphic rocks. In extra-peninsular regions, gold is met with in rocks of different periods; in Ladakh in quartz reefs of carboniferous age; in Kandahár in cretaceous formations; while along the foot of the Himalaya the tertiary rocks which flank the base of the hills are more or less auriferous. Holland (*l.c.* 45) has pointed out that India occupies the sixth or seventh position among the leading gold-producing countries of the world, but that the total output is nevertheless insignificant, aggregating no more than $3\frac{1}{2}$ per cent. of the world's annual supply. The following brief abstract of the available information regarding the occurrence and production of gold, province by province, may be useful:—

Production.

Origin
Geologically.

India's
Position.

Bengal.—Gold is obtained in Orissa, Midnapur, Bankura and in the Province of Chota Nagpur. In recent years attention has been drawn chiefly to the latter, where, under the control of the Geological Department, an extensive survey for gold has been conducted by several officers whose publications are mentioned below. The area examined covers part of the districts of Manbhum and Singhbhum, with the tributary States of Gangpur, Bonai, Udepur and Jashpur. Commenting on Mr. Maclaren's final report, the Director says that though gold is

en al.
Chota Nagpur.

undoubtedly almost universal in the country examined, gold-prospecting could not (with one or two exceptions) be honestly recommended as a reasonable venture (*General Report*, 1902-3). The examination found the deposits in the quartz reefs to be very thin and patchy and the ore bodies small. "The recovery of gold from alluvial deposits," the report further adds, "offers no brighter prospects than that of mining quartz veins." [*Cf. Noetling, Sonapet Gold-Field*, in *Rec. Geol. Surv. Ind.*, 1890, xxiii., pt. ii, 73-8; 1896, xxix., pt. i., 2; King and Pope, *Gold, Copper, Lead in Chota Nagpur*, 1891; Hatch, *Rept. Parhardiah Quartzites*, in *Mem. Geol. Surv. Ind.*, 1901, xxxiii., 68-71; Holland, *Gen. Rept. Geol. Surv. Ind.*, 1901-2; 1902-3, 10-4; Maclaren, *Rec. Geol. Surv. Ind.*, 1904, xxxi., pt. ii., 59-91 (with map).]

Assam.

Assam.—For an account of the gold of this province the reader should consult Maclaren's exhaustive paper on the *Auriferous Occurrences of Assam* (*l.c.* 1904, pt. iv., 205-32, with numerous plates and maps). In a brief notice on that paper, Holland (*Rev. Min. Prod.*, 1905, xxxii., 140) remarks that the most striking feature of the gold deposits of the Assam valley is the universal distribution of the metal in extremely small percentages throughout the gravel of the river-beds. This Maclaren holds to be due to two main causes, the wandering of the Brahmaputra over the plain and the wide distribution of the Tipam or Sub-Himalayan sandstones, which are certainly auriferous in places. The next characteristic feature is the general aggregation of gold at a point the distance of which from the hills is dependent on the strength of the current and the form of the gold dust. This point of general deposition is marked on the Assam rivers by the occurrence of gravels containing pebbles up to 6 inches in diameter. Above the point indicated the only deposition is that due to local diminutions in the velocity of the current, as on the beaches at the end of a long pool or on beaches lying parallel with the stream, and to which the gold is carried by the back eddies, where it is retained in the interstices between the large boulders.

River-beds.

Point of
Deposition.

Sadiya.

Dihong.

Subansiri.

The only gold deposits considered by Maclaren to be worthy of further prospecting are the Guri Mara, above the Sadiya and opposite the Chunpara Stockade; the Sibia Mukh on the Dihong river, and the Derpai pool on the Subansiri river. The most promising deposit is that on the Subansiri. The gold in general is of good quality, but the individual gold grains, except in a few places on the Subansiri, are extremely small and much flattened.

U. Prov.

United Provinces.—The production of gold in these provinces is comparatively unimportant. The only districts where it occurs in any quantity are Bijnor, Naini Tal and Garhwal, but the estimated production is only about 50 to 80 oz. per annum. The general method of working is the washing of auriferous sands found in the beds of certain rivers, most notably Ramganga, Sukhar Sot, Phika and Khoh in the Nagina Tahsil of the Bijnor district.

C. Prov.

Central Provinces.—Gold-bearing sands occur in most parts of these provinces, but the output is comparatively insignificant. The chief localities are Nagpur Division, especially Bhandara, Balaghat, Chanda, etc. [*Cf. H. Nunn, Monog. Gold and Silver-Ware*, 5-10.] In Central India gold appears to be confined to the Ajmere-Merwara district.

Panjáb.

Panjáb.—The districts where gold is found are Bannu, Peshawar, Hazara, Rawalpindi, Jhelum, Kangra, Ambala, Gurgaon, and Hoshiarpur. The most important are the Jhelum district, where gold to the value of £770 was produced in 1901, and a fair amount in the Hazara district. It is said that recently an application has been made to the Panjáb Government on behalf of a Syndicate in British Columbia for the grant of a dredging lease for gold in the bed of the Indus. [*Cf. MacLagan, Monog. Gold and Silver Works*, Pb., 1888-9; Robertson, *Settl. Rept. Rawalpindi*, 1893, 15; *Mem. Geol. Surv. Ind.*, 1897, xxvi., 287; *Madras Weekly Mail*, June 7, 1900, 502; *Capital*, Feb. 4, 1904.]

Kashmir.

Kashmir.—Gold-washing is carried on in some villages, chiefly in the Skardu Tahsil and Kargil Tahsil, Baltistan. In the former, the chief locality is the sands of the Bashahr river, and in the latter along the left bank of the Dras-Sooroo river from Hardas to Maimus, at Sher Alithang near Kharbu, and at Chuskor, some eight miles from Kargil. The market value of a *tola* is Rs. 20 and the State rate Rs. 18. [*Cf. Drew, Jummo and Kashmir*, 1875, 409; Clarke, *Skardu Tahsil and Kargil Tahsil*, 1901, 10; Kaye, *Note on Assess. Rept. of Kargil Tahsil*, 1901, 45; Lawrence, *Valley of Kashmir*, 62.]

Bombay.

Bombay.—Auriferous rocks occur in the districts of Dharwar, Belgaum, Kaladgi, the South Maráthá country, and in the province of Kathiawar, but the output of gold in late years has been very small. Recently, however, promising work

in reef-mining has been commenced in the Dharwar district under the auspices of the Dharwar Reefs Company, Ltd.

Madras.—Gold is found in Madura, Coimbatore, Salem, Wynaad, the Nilgiris, Travancore, Malabar, Kanara, North Arcot and Bellary. In recent years, however, all the gold produced in the Presidency was from the Kangundi mines in the Kangundi Zemindari of North Arcot. Work was commenced there in 1893 and was continued with varying success until 1900, since when working has ceased. The highest yield was obtained in 1898, viz. 2,854 oz. Prospecting has recently been carried on at Wynaad and three of the old mines were open during part of 1901, but did not yield any gold. [Cf. Hayden and Hatch, *Gold-Fields of the Wainád, Mem. Geol. Surv. Ind.*, xxxiii., pt. ii.]

Madras.

North Arcot
Mines.

Mysore and Hyderabad.—The gold of Mysore State is solely derived from the Kolar district, which occupies a small tract of country in the eastern extremity of the State. Roughly, the field is about ten miles long from north to south, two miles wide from east to west, and made up of synclinal folds of schistose rocks. Hatch says that the auriferous lodes of the Kolar gold-fields consist of a series of parallel quartz veins which occupy a central position in the belt of Dharwar schists. Although there are several parallel veins, it is on the Champion lode only that paying mines have been developed. "The attention of European prospectors was directed to this area by numerous Native workings of unknown age; and since operations commenced on a large scale, shortly after 1880, the gold extracted, up to the end of 1903, has reached a value of nearly 19 millions sterling. During this period five companies have paid £8,250,000 in dividends, while the Mysore State has received nearly one million as its royalty. The deepest workings, now somewhat more than 3,000 feet below the surface, show little diminution in the value or width of the auriferous quartz vein. During the past five years the amount of quartz crushed has increased from 337,636 tons in 1898 to 546,752 tons in 1903, and the value of gold extracted has increased from £1,576,000 in 1898 to £2,284,000 in 1903." [Imp. Gaz., 1907, iii., 14.] Holland observes that various improvement schemes, with the object of reducing working expenses, have been introduced in recent years, one of the most important being the provision of electric power from the Kauveri Falls. The supply commenced about the middle of 1902, and has regularly furnished over 4,000 horse power to the various mining and metallurgical works. In *The Madras Weekly Mail* (June 1, 1905, 597) an account is given of a new discovery of gold in Mysore at Yellahanka, 22 miles north-east of Bangalore, which seems of future importance.

Discovery.

The citation of publications in the opening paragraph practically denotes those of Madras and Mysore, but there may be added the annual reports of the various companies, of which, in alphabetical sequence, the following may be quoted:—1. Balaghat Gold Mining Company; 2. Champion Reef Gold Mining Company; 3. Coromandel Gold Mining Company; 4. Ooregum Gold Mining Company; 5. Mysore Reefs Company; 6. Mysore Gold Mining Company; 7. The New Kempinkote Gold Field; 8. Nine Reefs Company; 9. The Nundydroog Company; 10. The Oriental Gold Mining Company; 11. the Road Block Gold Mining Company, etc.

ines.

In Hyderabad the only quartz mines producing gold are those of Hutti and Wundalli in the Nizam's Dominions. At the Wundalli mine 7,822 oz. of gold were recovered in 1899, but the mines were closed in 1900, and the Hutti mine was the only one at work at the end of 1903. In the latter mine the total output for 1903 was 3,414 oz.

Hyderabad

Burma.—The only reef mine of importance is the Kyankpazat ne Wuntho in Upper Burma. Holland tells us that this mine yielded in 1898, 1,120 oz., and maintained indeed increased its yield until 1902, when 1,984 oz., valued at £7,606, were produced, but in 1903 the auriferous chute was worked out and the mine closed. From recent exploration, however, Burma appears to be very rich in alluvial gold, and in 1903 a license was issued to a Company to dredge gold in the Irrawaddy above Bhamo. Gold to the value of Rs. 2,016 was produced, and the result was sufficiently successful to induce the Company to extend its operations. The greater possibilities of dredging on the Irrawaddy appear to arise from the fact that the waters of the river are derived from ranges where, even in the cold weather, there is a heavy rainfall. [Cf. *Imp. Gaz.*, 1907, iii., 141-3.] *The Indian Agriculturist* (Feb. 1905) gives the practical results of an interview with Lt.-Col. Mackenzie Foss, on the subject of the occurrence of tin and gold in Lower Burma, in which that gentleman apparently stated that, in his opinion, the district of Mergui was one

ur a.

Irrawaddy.

Mergui.

of the richest in alluvial gold in the world. [*Cf.* Nisbet, *Burma under Brit. Rule and Before*, 1901, i., 347, 397; *Rec. Geol. Surv. Ind.*, 1892, xxv., 129; 1893, xxvi., 7, 48, 163; 1894, xxvii., pt. i., 10-11, 117, 122-3.]

Uses.

Uses.—Gold is largely employed by the richer classes in India for the purpose of personal adornment or in the ornamentation of sacred buildings, palaces, etc. The most important art industries for which it is employed are, therefore, coins, jewellery, gold-leaf, gold wire and thread (used in the fabrication of cloth of gold (*kinkhab*), braids, lace, etc. Stein (*Ancient Khotan*, 1907, 192-4, 210, 224, 381, 496) discusses the gold-digging at Yotkan and mentions the instances where he found gold employed by the artists of the sand-engulfed ruins. These date from the 3rd to the 8th centuries. While he found gold-leaf extensively employed in the ornamentation of the idols, statuary, etc., he makes no mention of having come across an example of fabric with gold wire (thread). He met with Chinese and Tibetan brocaded silks, but no examples of the Indian *kinkhab*.

Medicine.

For the uses of gold in MEDICINE, the reader should consult Dutt (*Mat. Med. Hind.*, 1900, 57-61). [*Cf.* *Ain-i-Akbari* (Jarrett, transl.), iii., 315-6; Mukharji *Art Manuf. Ind.*, 1888, 97-144; *Ind. Art at Delhi*, 1903:—Gold and Silver Plate, 31-42, Gold Brocades (*kinkhab*s, etc.), 319-38, Gold-wire, 416-8, Gold and Silver Embroidery, 419-24, Jewellery, 489-93. The following enumeration, province by province, of the publications that deal with the Indian industries that employ gold may be found useful:—BENGAL: Mukerji, *Monog. Gold and Silver Work*, 1905. ASSAM: Henniker, *Monog.*, 1905. UNITED PROVINCES: Hoey, *Monog. Trade and Manuf.*, 110-3, 157, 184, 194, 196-7; Charles, *Monog.*, 1905. PANJAB: MacLagan, *Monog.*, 1890. CENTRAL PROVINCES: Nunn, *Monog.*, 1904. BOMBAY: Burns, *Monog.*, 1904. MADRAS: Havell, *Rept. Arts and Manuf.*, *Govt. Proc.*, 1886, 5, 6, 13, 15. BURMA: Max and Bertha Ferrars, *Burma*, 1900, 107-11.]

Trade.

TRADE.—If Max Müller and others be correct in identifying India with the Ophir of Scripture, the present production is possibly only a tithe of what it has been. According to Napier (*Metallurgy of the Bible*), King David derived, through the trade of Ophir, gold to a valuation of £600,000,000. But another opinion fixes Ophir in West Arabia. Pliny speaks of Indian gold coming from the country of the Nareæ (the Nairs of Malabar), and thus practically the Mysore mines.

Imports.
Declining.

“Within the past few years the net imports of gold have apparently diminished. Thus the excess of imports over exports during the ten years ending 1891-2 averaged about 729,900 oz., while during the following ten years the average did not exceed 442,400. The reduction is mainly due to two causes. Large imports of gold had been made by banks to be exchanged for silver, and the accumulation of gold coin having been found inconvenient by Government—for gold does not circulate freely in the country—the surplus was shipped by the Government to London, where at the same time considerable purchases of silver were made for additions to the coinage. Secondly, the Mysore gold-mines now send to London large quantities of gold every year, and this export reduces the net imports shown in the trade returns. It is probable that on the whole there was no real decline in the demand for gold in India, which is in value about half of that of silver. In 1902-3 the net imports rose to 1,417,000 oz., and in the following years to 1,566,237 and 1,516,991” (*Imp. Gaz.* 1907, iii., 292).

Indian
Produc-
tions.

Holland (*Rev. Min. Prod.*, l.c. 47), commenting on Indian production, observes, “For the six years under review the value of gold extracted was £11,310,038 or 60 per cent. of the total value (£18,687,818) extracted in the twenty-one years since the commencement of work under European supervision. With the increase in output dividends have also increased, rising from £739,114 in 1898 to £1,019,347 in 1903, or an increase of 38 per cent. The total dividends paid during the six years were £4,988,793 or 60 per cent. of the dividends (£8,287,071) paid since 1882, indicating that dividends and output have advanced *pari passu*.” [*Cf.* O’Conor, *Rev. Trade Ind.*,

Dividends.

1902-3, 28-9, 37-8; *Rept. Beng. Chamber Comm.*, 1903, 145-51; *Imp. Gaz.*, 1907, iii., 291-2.]

G YPIUM (Cotto); Watt, *Wild and Cult. Cotton Plants of the World*, 1907, 1-406, tt. 1-53. A genus of MALVACEÆ, the species of which are widely distributed on both sides of the equator, and in both hemispheres. On the north they extend, under cultivation, to Crimea (45°), and on the south to the latitude of the Cape of Good Hope (34°).

Few cultivated plants are so difficult to understand or have been half so much confused through conflicting opinions regarding the existing forms as the cottons. Practically all the botanical names in current use were founded on cultivated plants, and these changed subsequently, and in some cases so rapidly that they are now mostly unrecognisable. Instead of rejecting a nomenclature thus hopelessly useless, one botanist after another has given his peculiar views and reassorted the published names. The obvious duty of establishing species on the wild forms and grouping the cultivated states as near as may be possible under these, has been absolutely neglected and the literature of the genus become confusion worse confounded. Useless controversies have engaged attention, such as whether there are fifty or more species, or only three, or even only one in the whole world; another, whether a single characteristic of supreme value can be discovered, upon which a classification of the forms might be based. The early authors divided the cottons into trees and bushes, or into perennials and annuals. It has now been established beyond dispute that all species of *Gossypium* under suitable environment are perennials if left alone, and may in time become large bushes or even small trees. Moreover, when cultivated they readily respond to environment, and when necessity exists become annuals or otherwise adapt themselves. On dry stony soils they are usually perennials, on rich loamy soils annuals, more especially if restrained by cold in the winter months or by a heavy periodic (monsoonic) rainfall or by infestations of pests. Some writers have placed confidence on the characteristics of the seed as affording a key to classification. If possessed of a double layer of wool, viz. an under-velvet or fuzz (as it has been called) and an outer layer or floss (the true wool or lint), such seeds have been regarded as denoting very different plants from those with a naked seed, that is to say, not possessed of the under-coating (fuzz). This conception originated the classification into *album* (white or fuzzy seeds) and *nigrum* (black or naked seeds). So again the fact of the seeds being free from each other or attached together into what has been called a "chain" or "kidney" mass, has been accepted as a further means of diagnosis. But as opposed to such views it has recently been shown that certain structural peculiarities have originated in consequence of adaptation to beneficial insects, such as the *kelep* ant of Guatemala, or as protective measures against enemies. Of this latter kind may very probably be the formation of the floss and of its special and varied peculiarities. Hence another set of writers have rejected all the distinctions based on the fruit or seed and have advanced the argument that selection should primarily be directed towards lowering the size and weight of the seed, and thus increasing the proportion of wool. No structural manifestations would accordingly be less constant than those based on the seed and floss. But the colour of the fuzz and floss have been even more frequently utilised as aids in classification than structural characters. The names *Nanking*

and *religiosum* were at first used to denote a red or *kakhi* coloured floss, and the belief was accepted that all wools of that colour were obtained from one and the same species. As opposed to that view it may be mentioned that Fortune (*Three Years' Wanderings in China*, 1847, 264) says that the *mie wha* or yellow cotton of China cannot be separated from the white form, and that the seed may come up either white or yellow. [*Cf. Liotard, Note, Nanking Cotton in India*, 1883.] As a matter of fact it would now appear certain that most wild cottons have a red-coloured fuzz or even a red fuzz and floss: accordingly, under negligent cultivation or as acclimatised escapes from cultivation, the woolly coating of the seeds, in the majority of species, may become reddish coloured. Conversely, red-coloured cottons, if carefully cultivated, invariably lose their colour and become white. Lastly, still other writers have sought for a classification based on the shape and degree of hairiness of the leaves and bracteoles or the shape and colour of the flowers. But, as with most other cultivated plants, the classification of the forms of *Gossypium* is alone possible on the basis of the wild plants and through an aggregation of all natural characteristics, including geographic and climatological considerations, and not upon any arbitrary (single) standard.

In this view it may now be desirable to furnish the practical results of a special study of the genus *Gossypium* (restricting attention as far as may be possible to the Indian forms) and to draw up the history of the available information regarding the cotton industry, with special reference to the periods of discovery, the stages in cultivation, the improvement of the plants of commerce, and the progression in industrial knowledge:—

istory.

I. THE HISTORY OF THE COTTON PLANT AND COTTON INDUSTRIES.

It would not be far from correct to describe cotton as the central feature of the world's modern commerce. Certainly no more remarkable example of a sudden development exists in the history of economic products than is the case with cotton. The enormous importance of the textile to-day, in the agricultural, commercial, industrial and social life of the world, renders it difficult to believe that but little more than two hundred years ago cotton was practically unknown to the civilised nations of the West. But it is perhaps even still more singular that a fibre which, for many centuries apparently, had been a staple article of clothing in India and the East generally, should scarcely find a place in the early classical literature of these countries. Nearly all the beautiful and useful plants of India have their properties extolled by the Sanskrit poets, and indeed are frequently dedicated to the gods, but cotton—the plant above all others which might have been expected to have formed the theme of nature-worship—is hardly more than incidentally mentioned.

Indian

Known

The Sanskrit word *kārpāsā-ti*, often rendered cotton, is connected with the Greek and Latin *carpasos* or *carbasus*, and denoted a fine textile. That name was also known to the Phoenicians and Hebrews, but whether it originated in India or was imported there would be hard to say. Mr. F. W. Thoas, who has kindly permitted me to consult him on this point, informs me that "the earliest mention appears to be in the *Asvalāyana Śrauta Sūtra* (say 800 B.C.), where the material is contrasted with silk and hemp, as that of which was made the sacred thread of the Brahmans. Probably the word was thus borrowed from India. The other words *tūla* and *picu* are later—they denote the substance." "The Sanskrit dictionaries give four names (*vadara*, *kārpāsī*, *tundīkeri* and *samudrāntā*) for the shrub, while the wild kind is called *bharadvāja*. They also mention that *kārpāsa* and *vadara* (the material) come from the fruit of the plant. The question, while the *Harsacarita* (circa 650 A.D.) twice speaks of the cotton (*tūla*) from the pods of the *śālmali* tree" (= *semul*, *Bombax malabaricum*). In the *Institutes of Manu* injunctions exist that regulate the operations of the washermen and of the weavers, and these all point to a social organisation and industrial attainment which a knowledge

of cotton is essential, but it is taken for granted rather than expounded or justified. All this might of course argue antiquity, as it certainly does for the arts of spinning and weaving, but the word *kárpási* may have existed for centuries with a generic rather than a specific signification.

Similarly it is extremely difficult, if not impossible, to determine the earliest certain references to cotton in the Persian, Arabic and European classics. It is fairly clear that *kutn*, *katán* or *kutun* (the Arabic name from which we have derived the English word cotton) originally denoted flax, not cotton. So also in Greek, *karpasos*, often rendered cotton, had, as already stated, the still earlier meaning of flax or simply of a fine textile. But cotton textiles had been carried to Europe, and were regularly traded in, long before any definite knowledge existed there regarding the fibre of which they were made. In fact the Greeks first learned definitely of the cotton plant through the group of explorers who visited India along with Alexander the Great and his immediate successors in Bactriana. Herodotus (450 B.C.) had written of India having *wild trees* that bear fleeces as their fruits. But right down to the middle of the 18th century the wool-bearing trees were divided into those with spinose and those with smooth stems. The former were the silk-cotton trees, of which *Bombax malabaricum* may be given as the type, while under the latter many of the botanical writers included *kapok* (*Eriodendron anfractuosum*).

A large percentage of the earliest authors speak of cotton being used for quilts and mattresses, but are silent regarding its being spun and woven. Ktesias would appear to have been the first European who observed the spinning and weaving of the Natives of India, but his description does not necessarily denote cotton as the fibre. Theophrastus (350 B.C.) gives us the first definite conception of Indian cotton cultivation. He says (*Hist. Pl.* (ed. Schneider), iv., ch. 4, 132), "The trees, from which the Indians make cloths, have a leaf like that of the mulberry; but the whole plant resembles the dog-rose. They set them in the plains arranged in rows, so as to look like vines at a distance." He then adds that cotton cultivation may be seen both in India and Arabia. Indian cotton-bearing plants set in rows necessarily involves cultivation, but it would be equally applicable to the perennial as to the annual plant. The comparison to the dog-rose, with its open lax branches, however, brings to mind the perennial *roji* of Gujarat rather than the small compact bush of the ordinary annual cotton. (See below, under *Roji*, p. 581.)

Pliny tells us that cotton (*carbasa*) was in Tylos called *Gossympines*. He does not state whence he derived that information, but curiously enough by modern botanical writers that word has become the generic name for the cottons (*Gossypium*). In the *Periplus of the Erythraean Sea* (63 A.D.) we have the first commercial mention of Indian cottons. The raw cotton, as also the Indian cotton manufactures, were conveyed by the Arabs from "Patiala, Ariake and Barygaza" (the modern Broach) up the Red Sea to "Aduli." The *Indika* of Arrian, a work compiled (150 A.D.) from Nearchus, Megasthenes, Strabo and Eratosthenes, as also other early Greek travellers, was professedly intended to supersede the inaccurate account of India given by Ktesias. After narrating the particulars above mentioned, Arrian adds that the cotton of India is whiter and brighter than that of any other country. Thus by the beginning of the Christian era we have a fairly vivid glimpse of India as a cotton-growing and cotton-manufacturing country. Stein (*Ancient Khotan*, 1907, 374, 412, 430, 442, etc.) mentions that cotton cultivation is very largely pursued around the modern Khotan, and in other passages he refers to fragments of cotton garments, etc., found in the ruins of the ancient city, which must be accepted as dating from the 3rd to the 8th century. These are doubtless the oldest authenticated examples of the Central Asiatic cotton industry at present known.

The simple reference to a fibre or textile, under such names as *kárpási*, *katán*, *linon*, *carbasa* or *Gossypion* may be of no historic value whatever. It has to be shown that the word used had the same signification then as to-day. Many illustrations might, in fact, be given of the confusion that prevailed regarding the separate recognition of the chief textiles of the world, down even to the 17th cent. y. In Manchester, for example, a particular texture of goods, woven of wool, was in 1590 sold under the name of "Manchester Cottons." In 1664 the dispute between Sir Martin Noel and the East India Company as to whether "Calico was linen or no" became acute, and that controversy shows how very reluctantly the name "cotton" was in England accepted as indicative of a distinct fibre.

Arab Authors.

There is, however, every reason for believing that the Arabs knew of cotton and wore cotton garments before the present era. Unhappily no writer can be discovered who effectually bridges over the gap between the period of the *Periplus* and that of the physicians who wrote in the 7th to the 10th centuries. Serapion, an Arab medical writer (who lived about 850 A.D.), quotes several earlier Arab authors, among whom Ibn Hanifa, he says (speaking of Kelbe), described the cotton as growing there on trees which lived for twenty years but attained their best bearing condition about the ninth year. Renaudot gives a translation of the journal of an Arab (Sulaiman) who visited China and India in the 9th century. The original Arabic MS. bears the date 1173, and was translated in 1718 by Renaudot, and again in 1845 by Reinaud into French; but there is an English edition dated 1733. Speaking of the town of Calicut, he says that "garments are made in so extraordinary a manner that nowhere else are the like to be seen. They are for the most part round and woven to that degree of fineness that they may be drawn through a ring of middling size." Sulaiman also makes special mention of the fact that the Chinese, rich and poor, were seen to be dressed in silk, but he says nothing of cotton in China. It is one of the many surprises met with everywhere in the study of the world's production and trade in cotton, that the plant was not cultivated in China for its fibre until the 13th century. In the 6th century we read of the Emperor Ou-ti having possessed a robe of cotton that he held in much esteem. Towards the end of the 7th century cotton was an ornamental shrub in Chinese gardens. Mayer says that it was not until about 1000 A.D. that the plant was fully introduced into China, and this view is accepted by Bretschneider. There was apparently in China (as in Europe) much opposition to the introduction of cotton as a textile.

Drawn through a Ring.

Cotton in China.

Indian Perennial Cottons.

Marco Polo (who travelled through a large portion of Asia in 1290 A.D.) refers to the production and manufacture of cotton in Persia, Kashgar, Yarkand, Khotan, Gujarat, Cambay, Telingana, Malabar, Bengal, etc., but is absolutely silent on these subjects in connection with China. Speaking of Gujarat, he says the cotton trees are of great size and attain an age of twenty years, but he adds, when of that age the cotton is only used to quilt or stuff beds. Referring doubtless to Masulipatam, he says it produces specially fine "buckrams" (muslins) and chintzes. The Rev. E. Terry, Chaplain to Sir Thomas Roe's Embassy to India in 1615, speaks of the cotton plants near Surat as growing for three or four years before being uprooted. The cotton plant seen by Rheede in Malabar, during 1686, he describes as a shrub 10 to 12 feet in height, found growing in sandy places—he does not say cultivated.

Cotton in Egypt.

Turning now and very briefly to Egypt. Pliny, in his account of Æthiopia, speaks of the portion that borders on Egypt having cotton plants that afford a more woolly fibre than is customary and as possessing exceptionally large pods. Yates (*Text. Antig.*, 1843, 334-54), commenting on that passage, observes that the plant referred to may have been *G. arboreum*. He further says that cotton was not grown in Egypt proper during ancient times. In support of that view he affirms that the MS. copies of both Pliny and Julius Pollux (a century later than Pliny), that have been cited as upholding an ancient cultivation, have had that interpretation put upon them through marginal annotations which were made about the 14th century A.D. being taken as parts of the original text. He accordingly maintains that cotton was first cultivated in Egypt about the 13th or 14th centuries, and in support of that opinion mentions the fact that the Arab physician Abdullatiph, who visited Egypt in 1200 A.D., and published a list of the plants he saw, makes no mention of cotton. Further, Yates points out that the ancient paintings and sculptures of Egypt, while they show flax cultivation and purification of the fibre, give not the slightest indication of cotton. And this view is confirmed by Prosper Alpinus (*De Pl. Egypti*, 1592, 29), who makes the significant observation that the Egyptians in 1592 imported cotton for their own use from Syria and Cyprus, and only cultivated in their gardens, as a curious and ornamental plant, the *Gossypium* which he figured and described, viz. *G. arboreum*. He adds, however, that the Arabs make webs of that cotton which they call *seffa*. Forskal (*Fl. Eg. Arab.*, 1775, 125) indicates two forms of cotton met with by him: *G. rubrum*, which he says was known to the Arabs as *oth*, *hadice*, or *odjas* (from the description given, the plant indicated was very likely to have been *G. arboreum*, Linn.); while his second species (which he calls *G. arboreum*) answers fairly closely to *G. herbaceum*. [*Cf.* Adler and Casanowicz, *Biblical Antig.*, in *Ann. Rept. Smithsonian Inst.*, 1896, 1005.]

First cultivated there.

Arabian Knowledge.

Perennial Cottons.

It is thus very remarkable that the accounts given by the earlier authors

regarding Indian and Egyptian cottons almost all point to perennial, not annual plants, and so persistently as to suggest that the annual stock may have been a subsequent discovery obtained very possibly from Arabia.

In the 9th century Sicily was taken by the Saracens, and according to Abu Zacaria Ebn el Awam (Banqueri, transl., ii., ch. 22, 103) they at once introduced the cultivation of cotton. From the account given of the methods of cultivation the plant must have been the annual stock, now known as *G. herbaceum*. In the 10th century the Muhammadans carried the self-same cotton plant (as I take it) across the Mediterranean to Spain, and for three centuries thereafter Barcelona had a flourishing cotton industry. There would thus seem no doubt the plant disseminated by the Muhammadans was *G. herbaceum*, the species presently cultivated in the regions indicated. Where they obtained that plant may be a matter of uncertainty, but to-day the centre of its area of cultivation might almost be given as the northern tracts of Arabia and Mesopotamia, where it stands every chance of being indigenous. There is no doubt, however, that the Levantine (not the Indian) plant was closely associated with the early Saracens; their religion, their cotton and their sugar might be spoken of as the triple agents of their civilisation. As a cultivated plant, that cotton was carried by them to Constantinople, and very possibly through Turkey, Asia Minor, Armenia, Kurdistan and Mesopotamia to Persia, if not even to the frontier of India. So also they in time may have conveyed it to Egypt, in connection with their Baghdad trade, which on the conquest of Spain went *via* Alexandria. But before passing away from this subject it may be added that there would seem no doubt a limited cultivation of cotton had been established in Crimea and South Italy some short time prior to the European conquests of the Saracens, so that it is just possible it may have existed, if it was not indigenous in some of the islands of the Mediterranean, prior to the knowledge of its utilisation as a textile, just as the tea plant existed in Assam prior to its being brought from China by Gordon and Fortune. It is not surprising, therefore, that Dioscorides should make no mention of cotton. The cultivation of *G. herbaceum* in time, however, was diffused throughout the countries bordering both shores of the Mediterranean, and a cotton trade was established which held sway for several centuries.

It may perhaps suffice for the purpose of this work to indicate very briefly the chief historic facts in the rise and present position of the cotton production and trade of the New World and of the cotton manufacturing enterprise of Great Britain. The earliest mention of the English cotton trade appears to occur in a little poetic work entitled *The Politie of Keeping the Sea*. This is given by Hakluyt in his *Voyages, etc.* (i., 213), and was apparently originally published in 1430. The merchants of Genoa are spoken of as carrying silk, pepper, woad and cotton to England, and as taking back woollen goods. It is thus probable that at an even earlier date than indicated England procured cotton from the Levant, since the fibre is spoken of as an ordinary commodity. In 1492 Columbus discovered the West Indies and America. The Spaniards on their arrival in the New World found cotton being cultivated and manufactured, from the West Indies to Peru and from Mexico to Brazil. In 1498 Vasco da Gama sailed for India round the Cape of Good Hope. The success of that expedition gave to Western Europe a direct route to India, and struck a severe blow at the commercial supremacy of Venice and Genoa. "Thus previous to the discovery of America and the West Indies and for some time afterwards, England, and probably all Europe, were supplied with cotton from the Levant" (Milburn, *Or. Comm.*, 1813, ii., 279-82). Down to the close of the 16th century England obtained her cotton (a small demand) from the Levant, and her supplies of Indian cotton goods *via* the Mediterranean ports. As late as 1641 we read that "the town of Manchester buys cotton-wool in London, that comes first from Cyprus and Smyrna." The supply, if any, from the West Indies must accordingly have been very insignificant. The early historians of Brazil affirm that a cotton plant was found indigenous there, and that the Natives made use of it to supply the cotton of their simple needs. In Bahia it must have been cultivated, however, since De Souza speaks of it (1570-87) as cleaned with the hoe, two or three times a year. Pizarro in 1522 found cotton in Peru, and it has since been recognised in the ancient tombs of that country. De Vica is reported to have discovered, in 1536, a wild cotton in Texas and Louisiana. Thus then, when first made known to Europe, the American continent, as also the West Indies, possessed not only a cotton industry but both wild and cultivated cotton, independent of those of the Old World. But we know nothing for certain of

the species of American cottons until approximately two centuries after their original discovery.

United States
Cultivation.

The first attempt to grow cotton in the United States was in Virginia. It was not, however, until the second decade of the 17th century that systematic cultivation was organised, and then from seed obtained both from the Levant and from the West Indies. It took nearly a hundred years from that date before the plantations became of national importance, but the seat of the industry gradually shifted south and west. England began to manufacture cotton about 1635, and continued to draw on the Levant for her supplies of the raw fibre. An outcry against the imports of Indian cotton goods began to be raised in England. Marc-graf (who died in 1644) speaks of the cotton seen by him in Brazil as having the seeds united together—the condition we now call kidney-cotton. According to Samuel Wilson, Smyrna and Cyprus seed, by the close of the 17th century, had been successfully acclimatised in Carolina.

Efforts of the
E.I.C.

The 18th century opened with repressive legislation passed by the British Parliament against Indian calicoes, but witnessed the imports by England and Scotland of raw cotton amounting to 1,000,000 lb. Cotton was raised in Georgia from seed supplied from Chelsea by Philip Miller (the original stock of the green-seeded plant now known as *G. hirsutum*). In 1782 muslins were first made in England, and in that year South American or Brazilian cotton began to be regularly received. Two years later a ship which brought eight bags of cotton from America to Liverpool was seized on the ground that so much cotton could not have been produced in the United States. In 1786 the green-seeded cotton was in the States the most largely grown of all kinds, but in that year the black-seeded or Sea Island cotton was introduced from the Bahamas.

Through Patrick Walsh, Pernambuco cotton was successfully introduced into the United States in 1789. Dr. Hove was sent to India to study the Indian cotton trade and Indian cotton plants, but his mission was resented by the East India Company, and his report was not published for sixty years after his return to England. Shortly after the date of Hove's visit the East India Company commenced, however, a series of experiments with a view to improve the quality and increase the quantity of cotton produced in India. Up to this point England obtained her supplies of raw cotton from the Levant, India, the West Indies and South America, the finest qualities being spoken of as coming from Surinam and Cayenne. The century closed with the exports from the United States to England at 9,532,263 lb. and from India at 729,643 lb.

The 19th century opened with the cotton crop of the United States being returned 48,000,000 lb., contributed as follows:—South Carolina, 20 million; Georgia, 10 million; Virginia, 5 million; North Carolina, 4 million; and Tennessee, 7 million pounds. The exports from that crop to Great Britain were 20,000,000 lb. Total consumption of raw cotton in Great Britain came to 54 million pounds, the supply from India being 6½ million pounds, or just one-third of the quantity drawn from the new area—the United States of America. The first Indian cotton mill was built near Calcutta in 1818, and the first of the Bombay series in 1851. Improvements in bleaching, dyeing and cylinder printing soon placed British calicoes in a position to hold their own against similar goods from any other part of the world. Resist printing was introduced by Sir Robert Peel. The Sea Island cotton raised at Hilton Head, South Carolina, fetched the highest price then known. Mexican cotton-seed was introduced into Mississippi by Walter Burling, and by crossing with the existing plant was supposed to have improved the quality of the cotton very greatly. Mention, so far as I can discover, has never been made of any of the indigenous cottons of the States (if such existed) having been grown by the colonists. They grew first Levant cotton, then Miller's green-seeded cotton, and finally Sea Island cotton. Which of these was crossed with Mexican has not been stated, but presumably the green-seed, and this hint should be of value.

Cotton cultivation was systematically prosecuted in Egypt about 1821, and rapidly obtained a position in quality of staple second only to that of the States, but there is very little information as to the original stock or of the subsequent stages in the production of the better races now met with in that country. The year 1825 witnessed ruinous speculation in cotton. From 1829 to 1841 the East India Company made strenuous efforts to improve the Indian staple. Large sums were spent in the form of awards, and ten experienced cotton-growers were procured from the Southern States of America with a view to establish the cultivation of New Orleans cotton. Excepting in Dharwar, failure was the

INDIAN AND ARABIAN WILD COTTON

G YPIU
AC U
Levant Cotton

only result, and the subject was allowed to drop from public attention. In 1841 cotton yarns were in Manchester spun up to No. 450's, and the United States rapidly obtained a monopoly of the market in raw cotton. In 1850 the imports into Great Britain were 664 million pounds of raw cotton, and her exports of manufactured cotton goods were valued at £28,000,000. About this time a scheme was formulated in England to raise a sum of £20,000,000 to be expended in India during five years, in measures calculated to forward India as a cotton-producing country. The outbreak of the Mutiny put an end, however, to these negotiations. Commenting on the effect of the American Civil War and the Great Cotton Famine of 1862-6, Dabney (*The Cotton Plant*, U.S. Dept. Agri. Bull., 1896, No. 33, 14) very truly observes, "Probably no equally great industry was ever more completely paralysed or had its future placed in greater jeopardy than cotton-growing in the United States during the war of 1861-5." In 1863 a Cotton Commissioner was appointed for Bombay, and the year following for Berar and the Central Provinces. Cotton farms were established under these Commissioners. The Bombay Cotton Frauds Act IX. of 1863 became law, but it is generally believed it did more harm than good and was shortly after repealed. For the ten years ending 1859 Great Britain imported an average of 2,318,575 bales of cotton (each 400 lb.), and of that amount India supplied 405,291 bales. But the ten years ending 1869, which included the troublous times of the American war, Great Britain imported an average of 2,736,661 bales, of which India supplied 1,282,172 bales—the record year being 1866, when India furnished 1,847,759 bales. Thirty years later (1899) Great Britain took 4,065,617 bales, of which India furnished only 77,297 bales; but in 1903 the Indian portion slightly improved, Great Britain having taken 203,550 bales of Indian cotton.

India's Cotton
Commissioner.

The immediate response made by India during the cotton famine shows her capabilities, but as in the United States, so in India, the demands of her own mills had become a controlling factor in the amount available for export. But the 19th century closed with India, instead of exporting cotton goods, having become the largest single market for English manufactured cottons—its demands for British cotton goods having been just under £20,000,000.

India's
Capabilities.

The 20th century may be spoken of as characterised by a new feature, namely, the rise of Continental, American and Indian cotton-manufacturing enterprise seriously threatening the supremacy of England in the cotton markets of the world. The Tariff Commission's Report of June 6, 1905, may be said to have been written with a view to establish this new phase. From that publication the following may be abstracted:—In 1876-80 the annual consumption of cotton in the United Kingdom exceeded that of the Continent by 2,030,000 cwt., and that of the United States by 5,070,000 cwt.; in the period 1901-4 the annual consumption in the United Kingdom was 8,020,000 cwt. less than on the Continent, and 2,950,000 cwt. less than in the United States.

A New
Phase.

For further particulars of historic interest the reader should consult the chapter below on Indian Trade in Cotton. [*Cf. Donnell, Hist. Cotton*, 1872; *De Candolle, Orig. Cult. Plants* (Engl. transl.), 402-11; *Branner, Cotton in the Empire of Brazil*, in U.S. Dept. Agri. Misc. Bull., 1885, No. 8; *Nasmith, inaugural Address*, delivered 1896 (reprinted), *Ind. Text. Journ.*; *Handy, Hist. and Gen. Stat.*, in Dabney, *Cotton Plant*, 1896, 17-66; also *Bibliography of Cotton*, l.c. 423-33; *Eckardt, Der Tropenpflanzer* (suppl.), Feb. 1906, vii.]

ind and
Arabia.

There would seem little doubt that the writers who have supposed this to be the wild condition of *G. herbaceum*, *Linn.*, are in error, but not more so than those who have taken it for a naturalised and degenerate state of some American species. Moreover, no one would appear to have demonstrated by actual experiment the forms, if any, that have resulted from ing *G. Stocksii* hybridisation with other species, hence its influence on the Indian cultivated cottons must be accepted, for the present, as purely imaginary.

abitat.—Probably indigenous to North Arabia and Asia Minor. Not known to exist as a wild species anywhere. It occurs in the Mediterranean regions (Sicily, Malta, Greece, Crete, Cyprus, Algiers, Turkey), in Syria, Mesopotamia, Armenia, Persia, Afghanistan, Baluchistan, in the North-West Frontier Province of India, and in the northern portions of the cotton area of the United States of America. It may, in fact, be described as a warm-temperate species, and is at least one of the plants that yields, or formerly yielded, the so-called "Short-staple American Cotton" of commerce. There is every reason for believing that it was the species first cultivated by Europeans. It was the bushy, cultivated, annual *Gossypium* or *Xylon* first mentioned by botanical writers. Moreover (as already fully shown), the field plant of the Levant was the first commercial cotton of Europe, which, at an early date, was carried to the United States and there largely cultivated some time before the discovery of the other special races that ultimately drove it into a position of secondary importance. It was that discovery, in fact, that gave the States their supremacy and caused the area of production to move to the south and west.

From the practical standpoint it is essential, therefore, that a clear conception be obtained of the plant which in all probability was the species that first attracted the attention of European manufacturers. Dr. Roxburgh—one of the most accurate of botanists—described and prepared an MS. drawing of an Indian plant which he accepted as being *G. herbaceum*, Linn., but in that opinion he was in error, for, if any two cultivated species of *Gossypium* can be viewed as distinct, *G. herbaceum*, Roxb., and *G. herbaceum*, Linn., are so. As understood by Roxburgh, the Indian plant embraced Dacca Cotton (*G. neglectum*, Tod.), also the Berar and China Cottons (*G. Nanking*, Meyen). It was apparently with the object of primarily separating the Indian country cottons from the Levant plant that Todaro formed his *G. Wightianum*. That species was founded on but one form (*Oss. Sp. di Cot.*, 1863, No. 12, 47), but subsequently Todaro fell into the error of grouping several Indian plants with it.

Cultivated Forms.—The forms of *G. herbaceum*, Linn., that are deemed of greatest value are (a) those suited to cold countries, and (b) those in the United States that are so much hybridised with *G. hirsutum* that they are often accepted as grades of that plant. The large-leaved hairy states of this species require a much warmer climate than the sub-glabrous (and therefore more) typical conditions. Some of the recent writers, such as Cook (*U.S. Dept. Agri. Bull.*, 1906, No. 88, 8), would appear, however, to go to an unnecessary extreme when they affirm, as Cook does, that "the Upland type of cotton was recognised as a distinct species by Linnaeus under the name *G. hirsutum*, but many subsequent writers have erroneously confused the Old World species *G. herbaceum*, which is not cultivated in the United States, though often so reported." It certainly was very largely cultivated prior to 1732, and for many years thereafter, as the Upland Cotton, and I believe still survives, though mostly in a state of hybridisation with *G. hirsutum*.

G. rbore, Linn., *Sp. Pl.*, 1753, ii., 693 (excl. *syn.* Rheede); Todaro, *Relaz. Cult. dei Cot.*, 1877, 176-80, t. 1A; Aliotta, *Riv. Crit. Gen. Goss.*, 1903, 56-65 (in part); Watt, *l.c.* 81-91, tt. 7, 8. Tree Cotton of India and Africa, *deo kapás*, *nurma*, *manua*, *bajwara*, *red navsari*, *ram kapas*, etc.

abitat.—A small tree or large shrub which has often been claimed as originally an African species, but few botanists have discovered it anywhere in what could be regarded as an indigenous habitat. It has been reported as wild in Upper Guinea, Abyssinia, and Upper Egypt. [*Cf. De Candolle, Orig. Cult. Plants*, 405.] Certainly so far as botanical publications are concerned it was figured and described by Alpinus as an Egyptian plant a hundred years before Plukenet wrote of it, "*Gossypium herbaceum maderaspatense*." It is said to be met with in gardens (especially near temples) in Egypt, Africa, Arabia, India, but though much less abundant has also been found in China, Japan, Java and the Malaya. Lamarek (quoting Sonnerat, *Hist. Voy.*, x., 460), speaks of it as growing plentifully in the plains of Macassar. So far as presently known, the arboreous

India and
Africa.

form (which may be called the typical condition) can hardly be said to be cultivated as a source of fibre to-day, though according to Indian tradition it is the cotton that should be selected in preparing the Brahmanical string, and has often been affirmed was also the cotton specially used by the Egyptian priests in the construction of their robes. Many of the Arab writers speak of its fibre as spun and woven. The classic records of a "tree-cotton" carry us many centuries beyond the first mention of a herbaceous field crop, and what is even more curious still, most of the early writers on Indian cottons, such as Rheede, Terry, Rumphius, etc., describe and figure "tree-cottons" (from admitted personal knowledge), but say absolutely nothing about herbaceous field cottons.

Cultivated Forms.—I regard this species as embracing several fairly distinct forms, some of which at least have been assigned independent positions by certain authors. But while in these a natural assemblage of characteristics is preserved, hardly any one feature is constant. Thus, for example, the flowers may be yellow, the leaves may be very considerably hairy, and the velvet of the seeds may be grey or brown. The more arboreous form occurs chiefly (so far as India is concerned) as an ornamental garden plant. When grown as a field crop *G. arboreum* may be either an annual or perennial, and in the latter case is generally sown in rows, being thus employed to shade more delicate annual cottons or other plants. Moreover, the agricultural forms are so much modified, very possibly by hybridisation, that they cannot be regarded as constituting varieties—in fact, many of them are but climatic sports that lose their properties on being carried from one region to another. It may be accepted, accordingly, that in India at least the cultivation of *G. arboreum* is quite as ancient, if not more ancient, than that of any other cotton. Some of the Indian races referable to this species (primarily) may be regarded as having derived from *G. arboreum* the soft silky character of their flosses, while the length and strength of their staples have come from the other ancestral elements. In others a strain from *G. arboreum* would seem to have been sought on account of the strength thus imparted to withstand seasonal climatic changes—the plant for the most part becoming a hardy perennial.

Cultivated
Forms.

Climatic Sports.

There are any cultivated states of this species found all over India, Egypt and Africa. As already explained, these manifest a constant tendency to throw back towards the arborescent condition with dark purple flowers, whenever they are allowed to become perennial or to be naturalised. The following are some of the more remarkable varieties or cultivated races of this species:—

Var. sang nea, Watt, l.c. 91-5, t. 9; *G. sanguineum*, Hassk., Cat. Hort. Bog., 200; Todaro, Relaz. Cult. dei Cot., 1877-8, 179, t. 1. This form is rarely met with in India, though frequent in Africa. A red-flowered herbaceous field cotton was, however, at one time common in India, and is occasionally still met with in Oudh. Buchanan-Hamilton, who gave special attention to the subject of the Indian cottons, did not apparently preserve a specimen of *G. arboreum* proper in his herbarium. Sets of his plants are to be seen in the Kew, the British Museum, the Wallichian and more especially in the Edinburgh herbaria, and among these may be discovered admirable samples of a red-flowered herbaceous plant which botanically is derived almost immediately from *G. arboreum*, with possibly a strain of *G. Nanking*. Of that plant Buchanan-Hamilton has recorded the following observation:—"No. 1549, *G. nigrum*, vide Comment. meum in Hort. Mal. p. pri m. var. (a) *rubicundum*; *G. indicum*, Willd., Sp. Pl., iii., 803? *Colitur ubique in India vulgarissima*." Now if the plant shown by that specimen was cultivated everywhere in India and very common in 1808, it must, I fear, be spoken of as very nearly unknown to-day and its place taken by a multitude of forms of yellow-flowered plants considerably more remote from *G. arboreum*, Linn. Of these may be mentioned:—

en al
Cotton.

abitat.—A large pyramidal bush, chiefly grown as a field crop. Cultivated

throughout Bengal, Assam and the United Provinces, less abundant in South India and Burma, distributed by cultivation to Africa, the West Indies and China. The names given to this plant, and the traditions of the people of India regarding it, suggest its having originated in the drier tracts of the Gangetic basin. Recently it has been carried to all the regions where the perennial cottons (presumably of *G. Nanjing* origin) formerly prevailed, and the craving for a short cheap staple has even seen its attempted cultivation in Gujarat and Kathiawar—the home of what may be characterised as the long-staple cottons of India.

Early
Records.

In point of historic sequence, the earliest botanic reference to this plant would appear to be that in the *Hortus Malabaricus* (1686), thus associating it with India, the headquarters of its present-day cultivation. Rheede speaks of it as a shrub 10 to 12 feet in height, found growing in sandy places. But as if to remove the possibility of its being supposed to be *G. arboreum*, he carefully describes the long, narrow segments of its smooth, soft leaves, and then adds that the flowers are pale yellow with purple claws and the seeds have a white to grey fuzz. Buchanan-Hamilton, who wrote a commentary on Rheede's great work in 1822, and had himself visited Malabar, observed that so far as he had seen in that district, cotton was raised (as Rheede had described it) by the Natives in the form of small trees planted in corners of gardens and not in fields, nor was the cotton for sale. But Buchanan-Hamilton, unfortunately, had come to the conclusion that all the cultivated cottons of India were mere races that differ from each other vastly less than do the varieties of the cabbage. He thus did not allow himself to realise that even accepting so restricted a botanical view, they might still be of great agricultural and commercial value, and therefore worthy of separate recognition. Accordingly, he omitted to add that the cotton of Malabar might be described as a perennial state of the self-same plant to which he had at one time assigned the name *G. viridescens*. On the other hand, Roxburgh, commenting on Rheede's *Cudu pariti*, observed that he could not bring himself to believe that it was *G. arboreum*. The fact that it was a small tree and thus a perennial precluded him apparently from assigning it its true position along with the "Bengal and Dacca Cottons," to which he most unfortunately gave the name *G. herbaceum*.

Restricted
Botanical
View.

Races.

The cultivated races of this plant known to exist in India are very numerous and much diversified as to yield and merit of staple. Perhaps the most significant feature of the story of this variety is that while to-day it affords the most inferior grades of Asiatic cottons, at one time it seems to have yielded several superior staples. Of these may be mentioned the much-talked-of Dacca cotton.

Dacca
Cotton.

aro
Cotton.

Var. assa ca, Watt, l.c. 108-12, t. 13; Darrah, *Note on Cotton in Assam*, 1885; Middleton, *Agri. Ledg.*, 1895, No. 8, 19-20; *G. ceruuum*, Todaro, *Oss. Sp. di Cot.*, 1863, 31; Garo Hills Cotton, *kil* or *borkapah* (large cotton), *khungi deva*, etc.

This very remarkable cotton might fairly well be described as an extreme form of *var. neglecta*. It is raised as an annual crop by the people of the Garo hills, who use it in the fabrication of a peculiar kind of blanket, which is formed by rows of tufts of the wool placed by hand across the fabric and bound in that position by the weft being forced home on each such row. Whether this peculiar textile suggested the selection that has resulted in the production of the Garo hills long-boll cotton, it is difficult to say. Certain it is that when carried to other parts of India the plant throws off most of the characteristic features above indicated and becomes a large form of *var. neglecta*, or perhaps rather of *var. rosea*.

Varadi
Cotton.

Var. rosea, Watt, l.c. 112-4, t. 14; *G. roseum*, Tod., *Relaz. Cult. dei Cot.*, 164-8, t. 2; *Nurdki Cotton*, Middleton, l.c. 11; *G. roseum*, Gammie, *Ind. Cot.*, 1905. The *varadi*, *katil belati*, *nimari*, *bangai* (Sylhet), and *nurdki* (Bengal).

This is in reality but an extreme form of *G. arboreum*, Linn. *var. neglecta*. When shown a typical example of this plant by itself (such as Wight's No. 213 from Coimbatore) there is little difficulty in admitting it to a varietal position. But when the study is extended to the cotton fields it is found that the transition into the ordinary form of *var. neglecta* is so gradual and continuous that it is impossible to separate the two. In fact, the so-called acclimatised Garo hills cotton of Nagpur might even more accurately be described as the present plant. The cultivators of India, being familiar with the normal condition, had brought to them this robust and hardy plant with its small pink-coloured flowers and large bolls, and they at once gave it distinctive names, such as those mentioned above. It is the most inferior of all Indian cottons, though the most prolific yielder.

CHINESE AND JAPANESE COTTONS

GO YPIU
AN I G
iam Cotton

Prolific
Low-grade.

The advance of the *varadi* cotton across India might be said to have been some few years ago regularly chronicled from district to district and hailed as a treasure by the advocates of low-grade cottons, while viewed as a calamity by others. Middleton says: "White-flowered cotton is a dangerous rival to the finer varieties. By nature it is made to supplant. When brought to a new district, instead of pining as most exiled cottons do, it develops all its best properties, grows robust, matures early, is prolific and so wins the favour of the cultivators; once established, it begins to degenerate, joins company with the worst of the native varieties, and forms the mixed growths that constitute the bulk of the 'Bengals' of commerce."

It is most curious that the name *vilayati*, often given to this as also to other robust races of *G. arboreum*, var. *neglecta*, should have begun to be used in Khandesh and Berar about the very time that the record exists of Major Trevor Clarke having supplied seed of a cross he had effected between the Garo hills cotton and Hinganghat. It is thus fairly certain that one of the first serious efforts to improve the Indian stock gave to the cotton growers of that country their most prolific though most inferior staple-yielding plant.

Cotton.

abitat.—An annual or perennial bush with delicately formed and often purple-coloured twigs; cultivated in China, Japan, the Malaya, Siam, Burma, India, the North-West Himalaya, Persia, Central Asia, Celebes, Upper Egypt and Africa (doubtfully in Madagascar and Arabia). No person has recorded the discovery of the wild state of this protean species, and yet its specific characteristics are so constant with many of the cottons, within a large part of the areas indicated, that the separation of the assemblage, from *G. herbaceum*, *G. arboreum*, and *G. obtusifolium*, not only meets a commercial necessity but coincides with many historic facts of importance.

Trigault (1615) says that cotton grows in great abundance but is not indigenous to China, in fact was introduced (? from Egypt) about four hundred years before his time. Dampier (*Voyages*, 1691) speaks of having seen a small cotton plant on an island near Formosa. One of the most interesting of the early writers on Chinese Cotton may be said to be Barrow (*Travels in China*, 1806 (2nd ed.), 556-7, 560). He tells us that the beautiful coloured cotton, known in commerce by the name of the chief city Nanking, was exported, the Chinese purchasing in exchange the cheaper white cottons of Bengal and Bombay. It was, he remarks, planted in rows and grew for three years, thereafter being uprooted and the fields prepared for other crops. Fortune (*Three Years' Wanderings in China*, 1847, 264) explains that the *kakhi* or Nanking cotton was a mere sport from the common white cotton of China.

Early
Records.

Economically *G. Nanking* is, at the present day, doubtless much more valuable than var. *sanguinea* or any of the other *G. arboreum* forms. Moreover, some of the *G. Nanking* series display characters of far greater interest than the mere length of the corolla (which Todaro lays stress on), and they might, in fact, be broken up into several varieties or distinctive races. Thus, for example, Bretschneider's specimen has the seeds black and almost devoid of an under-velvet—a character which brings to mind the naked black-seeded so-called indigenous cottons of South India (see below), but it is highly probable that both these may have to be regarded as indicating hybridisation with one of the naked-seeded forms. So again, some of the Indian examples of this species have purple flowers, others yellow with purple blotches, and in still others the flowers are pale yellow with a purple tinge on the extremities of the petals. A range of variability such as that can be best accounted for on the assumption that the assemblage embraces many cultivated races, of which each very possibly owes its peculiarities largely to hybridisation.

Baroda Perennial

are mostly grown on red sandy or stony soils, very rarely on black soils. They are for the most part perennials, and as such attain a height of 6 to 8 feet; they are accordingly largely cultivated as mixed crops, being grown in rows through the fields or as hedges to protect other crops.

Var. ani, Watt, l.c. 131-4; Middleton, l.c. pl. iii.; *G. herbaceum*, var. *Jethi*, Gammie, l.c. 4, pl. iv. This affords the finest and most silky qualities of the cottons known in trade as the *Oomras* (Amraoti), the Hinganghats, the Nagpurs and Bihars. Under each of these there are usually two grades, viz. the *bani* and the *jari*. The former grows on the higher and drier soils, especially of the southern districts; gives a fine silky floss but low yield. The latter is raised on the lower black soils of the northern districts; gives an inferior staple of a woolly character but does so very profusely. *Jari* seems originally to have been simply a lower quality of *bani*, and produced possibly by crossing it with var. *neglecta*; nowadays it is pure *neglecta*. To the circumstance of *Bani* being one of the races of the Chinese cotton plant is due its silky staple. The description of the shape of the leaves and colour of the flowers of this special form is almost precisely that given for *Nadam*, except that the leaves in the finest grades of *bani* are much larger, thinner in texture, more undulated and much more hairy. The bracteoles are usually very large purple entire, or with a few long pointed teeth.

It is met with over a wide area, bears numerous distinctive names, and manifests a considerable range in quality of staple. It mingles with the *Nadam* cottons of the south and east, with the *Raji* of the west, and with the *hima-layana* cottons of the north. It is known in Bihar as *jethi* or *desi* (*deshila*); in Bengal proper it is *bhoglla*; in Berar it has numerous synonyms such as *tidki*, *judi*; in Hyderabad one of the best forms is that produced at Bhainsi; in Southern Kathiawar it seems also to be known by the names of *mathio*, *tiffina*, *gangri*, etc. It occurs in Berar, the Central Provinces, Bihar and the drier tracts of Bengal. It is essentially the best cotton met with on all the dry soils that have to be classed as second best in cotton-production.

Var. oji, Watt, l.c. 134-7. A perennial, bushy, yellow-flowered, cultivated cotton that might be described as specially prevalent in Baroda and Khaira. It is a tall much-branched shrub, often climbing in hedges 6 to 8 feet with straight ascending branches. When left to grow in the hedgerows *roji* becomes subscandent, the wool shortens and turns rufous-coloured, and the fuzz lengthens and becomes also red-coloured. If allowed to remain in the fields for more than three or four seasons the wool degenerates in quality and, as stated by the early authors, is then fit for upholstery purposes only. But Middleton observes, "*Roji* is markedly different from the annual cottons and does not seem to hybridise with them."

One of the earliest and perhaps the most interesting direct allusions to this cotton is that given by the Rev. E. Terry, who accompanied Sir Thomas Roe's Embassy to India (*Voy. E. Ind.*, 1615, 368). Speaking of the neighbourhood of Surat, he says: "For their Cotton-wooll, they sow seed, and very large quantities of Ground in East-India are thus seeded. It grows up like small Rose-bushes and then puts forth many yellow blossoms. . . . Amongst that Wool they find seeds to sow again they have occasion; but those shrubs bear that Wool three or four years ere they supplant them. Of this Cotton-wool they make divers sorts of white Cloth." This recalls at once the description of Indian cotton given by Theophrastus (see p. 571).

There is only one perennial cotton with yellow blossoms in Gujarat, and accordingly it seems safe to assume it was the plant to which Terry referred. Here, then, we have another indication that the perennial cottons were once upon a time more largely cultivated than they are to-day, if we are not justified in believing that the perennial cottons were the early condition, the annual plant a later product of greater skill in cultivation. Hove (170 years after Terry's time) repeatedly alludes to perennial cotton seen by him—both red and yellow flowered—but he also gives a full account of the cultivation of the annual plant, and devotes special attention to what he calls a new method recently introduced. This may possibly point to the extended cultivation of the annual crop. But by the date of Hove's visit the *roji* cotton had been signed the secondary position which it has since held. Hove's actual specimens are in the British Museum, and it has to be admitted that they could not be separated botanically from any corresponding set of more recent date. But he has no sample of what

could be called a high-grade *kahnami*, his nearest approach to that being a specimen that might be described as the *wagria* cotton of to-day.

To conclude this account of the forms of *G. Nanking*, it may have been observed that I have not attempted to describe the races that might be mentioned as examples of each of the great groups, *Nadam*, *Bani*, *Roji* and *Himalayana*. But it is next to impossible to furnish descriptions that would be intelligible to persons who have not a personal acquaintance with the living plants. To the cultivators of India they are, however, often of considerable value. Into one or other of the varieties of *G. Nanking* have to be placed all the yellow-flowered perennial cottons with thick leathery, broad, five-lobed, imperfectly cordate leaves, having three glands and large ovate acute, thick-toothed bracteoles.

Indian
Wild
Cotton.

G. obtusifolium, Roxb., *Fl. Ind.*, 1832, iii., 183; Todaro, *Relaz. Cult. dei Cot.*, 1877-8, 129-30; Watt, *l.c.* 139-43, tt. 19, 20; *G. herbaceum*, Aliotta, *Riv. Crit. Gen. Goss.*, 1903, 67.

A shrubby very ramous plant with small leaves, having three, more rarely five, obtuse entire lobes, stipules falcate; *bracteoles* entire; *capsule* ovate, cells 3-seeded; *seeds* free, clothed with firmly adhering short greenish-grey down, under a small portion of ash-coloured wool. A native of Ceylon, but not cultivated. Flowered during the rains and cold season in the Botanic Gardens at Calcutta, where it was cultivated from seed obtained from Ceylon of a plant reported to be there wild.

The above, very slightly abbreviated, is Roxburgh's original account of this species. The additional information available may be said to consist of a manuscript coloured drawing made under Roxburgh's supervision and named by him, the original of which is in the Calcutta Herbarium, and an exact copy in the Royal Herbarium, Kew. It is, however, the plant called *G. herbaceum* by most writers who have described the cottons of India and Africa, and is the *G. hirsutum*, Linn. *Herb.*, but not of Linn., *Sp. Pl.* Roxburgh was apparently not aware that it was a wild plant in Khandesh and Gujarat, nor that it was the type of the most important cottons of India. Under the name *G. herbaceum* he described the plant now accepted as *G. arboreum*, var. *neglecta*, and linked that with *G. Nanking* (China and Berar Cottons), but kept all three distinct from *G. obtusifolium*. [No plant that could be supposed to correspond with *G. obtusifolium* is, however, mentioned in Linn., *Sp. Pl.*; in *Fl. Zeyl.*; in Burma, *Thes. Zeyl.*; in Rheede, *Hort. Mal.*; nor in Rumphius, *Herb. Amb.*, etc., etc.] Lastly, Trimen says there is no indigenous cotton in Ceylon.

Feral
Condition.

abitat.—A distinctly Oriental species, the various manifestations of which are met with in India, Ceylon, Malay Archipelago, Philippine Islands, Africa and Upper Egypt. I have in India repeatedly collected a *Gossypium* in a wild or self-sown condition, and was, I believe, the first person definitely to suggest its identity with *G. obtusifolium*. It occurs, for example, here and there all over Kathiawar. It is fairly common in the hedges of Gujarat, and was found by me in Khandesh and in the Deccan. If in all these instances it has to be regarded as but a survival of former cultivation, there would seem every likelihood that in some of its known habitats it has existed in the feral condition for a great many years, perhaps centuries. Further, the plant is perfectly easily recognised from all the other Indian cottons, though certain states of *G. Nanking* come very near to it indeed, if such instances are not hybrids between the two species. But the plant does not seem to be confined to India and Africa. Vidal collected it in the Island of Ticao, Philippines, and the label attached to his specimen describes it as "wild." So also Dr. A. B. Meyer found it in the Malay Archipelago.

Cultivated Forms.—To distinguish the cultivated forms collectively, of this species, from those of Africa and other parts of the world, it may be useful to group them as embraced under a special Indian variety as follows:—

Indian
Long
staples.

Var. Wightiana, Watt, *l.c.* 143-53, tt. 21, 22; *G. Wightianum*, Todaro, *Oss. Sp. dei Cot.*, 1863, 47-51; also *Relaz. Cult. dei Cot.*, 1877, 141-6 (in part), t. iv., ff. 1-9; *G. hirsutum*, Linn., *Syst. Nat.*, 1767, ii., 462; also in *Herb.*, non *Sp. Pl.*; *G. herbaceum*, Linn., var. *obtusifolium*, Roxb., Wight, *l.c.*, t. 9; Maxwell T. Masters, *Fl. Br. Ind.*, i., 346 (in part); *G. herbaceum*, Aliotta, in *Riv. Crit. Gen. Goss.*, 1903, 67 (in part). The so-called Long-staple Cottons of India.

One of the most remarkable features of this plant is the circumstance that while it is the most valuable of all Indian cottons to-day, it is the one least understood and last of all to have been described by botanists. It is a cultivated

annual cotton, with seeds much smaller, more definitely and compactly formed than in the wild plant, and fuzz very short, usually ashy-grey in colour. The change in the shape and size of the seed is a direct result of selection intended to lower percentage weight of seed to floss (lint). Varthéma (*Travels* (ed. Hakl. Soc.), 1510, 107) speaks of the cotton of Cambay being much exported; he also says Bengal cotton is sent to Mecca, and in a footnote mentions the cotton of Burma. Mandelslo (*Travels*, in Olearius, *Hist. Muscovy*, etc., 1638-40, many passages) makes frequent mention of the cotton of Gujarat and Agra, but not in such a way as to allow any opinions being formed regarding the plant that was then grown. In Milburn's *Oriental Commerce* (1813, i., 280) special mention is made of the Ahmood being at that time the finest grade of Gujarat cotton.

Early
Records.

abitat.—This is cultivated in a belt of country that fringes the west coast of India from the Rann of Kach through Kathiawar and Gujarat, to the southern Maráthá country and South India.

Soils.—The cultivated states of *G. obtusifolium* are exceedingly difficult to classify, since they blend almost imperceptibly from one type to another, in direct adaptation to smaller and less conspicuous climatic and soil variations than is experienced in the other cotton areas. There are in India three main classes of cotton soils with three corresponding main groups of cotton plants:—(a) Rich black loamy soils, such as those of Kathiawar, Gujarat, Khandesh or the Karnátak. These are collectively often spoken of as the "Black Cotton Soils." (b) Mixed red and black stony soils, such as those of the Deccan, Berar, the Central Provinces, etc. (c) Alluvial sandy soils such as those in the Ganges and Indus basins. Within (a) the forms of *G. obtusifolium* are mainly grown; (b) of *G. Nanking*; and (c) of *G. arboreum*. But in each one of these great cotton areas there may be local modifications both in climate, soil, exposure, etc., so that a limited cultivation of all three plants may exist or be possible in any one province. Speaking generally, however, *G. Nanking*, when met with on the black cotton soils, is of a superior quality to that seen anywhere else and *G. arboreum* is there very nearly unknown. These soils are too valuable to be used for the inferior grades, and consequently it is within *G. obtusifolium* itself, as a rule, that the adaptations of plant to environment have taken place. On the red and black stony soils *G. obtusifolium* rapidly degenerates or becomes hybridised with *G. Nanking*. In the areas of sandy dry soils *G. obtusifolium* becomes unknown, and the higher grades there met with are some of the stocks or hybrids of *G. Nanking*. It is not to be wondered at, therefore, that in regio so eminently suited for cotton as those possessed of black cotton soils, every little variation in soil, climate, altitude, marine influence, etc., etc., should have resulted in the production of special forms adapted, district by district, if not field by field. The most favoured conditions, and the localities accordingly of the finest Indian staples, are Surat, Broach, Ahmedabad and Kathiawar. But within even these four districts there are well-marked minor areas that have apparently directly originated some of the special forms of *G. obtusifolium* that have presently to be indicated. In 1891, and again in 1894, I had the pleasure of studying the cottons of Gujarat practically, on the last occasion in company with Prof. Middleton, now of the Board of Agriculture, who was at that time in the service of His Highness the Maharajah of Baroda. We marched over the greater part of the province as well as Kathiawar (when the cottons were in flower), and Middleton's great personal knowledge of the country enabled him not only to point out to me the kaleidoscopic blendings of the plants, but the immediate relationship of these to the variations in soil. [*Cf. Ann. Rept. Ind. Mus. Calc.*, 1893-4, 2-5.] The rich, deep black soil of roach and Navsari is known as the *kahnám*, and this was observed to yield the finest of all Indian cottons, accordingly known as the *kahnám* or Broach *deshi* (= country). The districts south-east of Baroda were seen to produce a considerably lower grade of *kahnám* cotton. So also both sides of the Dhadar river (between Baroda and Broach) were noted to change into a calcareous loam with the appearance of a distinctive plant known as the *goghari*. That particular cotton thus occupies an intermediate zone between the plants of the deep black *kahnám* soil proper and the lighter or shallower soils known as *goradu* to the north and west. On these lighter loamy soils are to be found the *kanvi* cottons of Bhavnagar, Palitana, Dhola, Amreli and Junagardh, the *ambli* (of Dholera), and the *wagriá* of Wadhwan, Viramgam, Morvi, North Kathiawar and Kach.

Cotton
Areas.Chief
Localities.*Kahnám*
Soil.

A similar classification doubtless prevails in the southern Maráthá country.

The *kumpta* (*coompta*) cottons of Dharwar and Belgaum are the southern equivalents of the *kahnami* cottons of Gujarat. Still farther to the South (in the Madras Presidency), the *uppams* of Tinnevely, Coimbatore, etc., closely correspond with the *goghari* cottons, while the *tellapatti* or *jowari-hatti* (hybrid) cottons of Bellary and Karnul in some respects answer to the *wagria* of North Gujarat.

Races.

The following may be given as the chief cultivated races of this species :—

(A) *Pure Races.*

(a) *Kahnami*: the *deshi* cottons of Broach, Surat, Navsari, Baroda, etc.

(b) *Goghari*: one of the inferior but profitable cottons of Baroda and Broach.

(c) *Lallo*: the *deshi* cotton of Ahmedabad and Kathiawar—the *Dhollera* Cottons.

(d) *pta*: the characteristic cotton of the southern Maráthá country and known in trade as "*Coomptas*."

(e) *Uppam*: the long-staple cotton of South India, found mainly in Tinnevely and Coimbatore.

(B) *Hybridised Races.*

(f) *vi*: a recently introduced stock that often bears the name of *khan-puri* and is probably a hybrid with *G. arboreum*, var. *neglecta*.

(g) *Wagria*: the Common Cotton of North Gujarat, Kathiawar and Kach; is probably a hybrid with *G. Nanking*—hence the breadth of leaf.

(h) *Tellapatti*: the black-seeded cotton of South India that is often called *jowari-hatti*, and which is found in Bellary and Karnul. There would seem little doubt that this is a naturally produced hybrid between the *uppam* and Bourbon cottons.

(B) *NEW-WORLD FORMS (OR, RATHER, INDIAN EXOTIC COTTONS).*

Exotic
Species.

For the purpose of this work it is hardly necessary to deal with every species and variety simply on the ground that at some time or other it may have been grown in India, or may even exist as an acclimatised (wild) plant. It is desirable to confine attention to the forms that can be said to be regularly cultivated, and which, therefore, participate in the supply of cotton that finds its way to market, or which have contributed (by hybridisation) to the production of some of the special races now grown in India. Suffice it to say that every cultivated cotton of any note in the world has at some time or other been experimentally grown in India. In all but two cases these have ultimately, however, come to be regarded as less valuable than the Asiatic stocks; hence certain forms, being neglected, have escaped into the neighbouring hedgerows or jungles and thus survived to this day, under conditions that have occasioned their being mistaken for indigenous (wild) plants. It may, therefore, serve the present purpose if the exotic cottons of India be discussed under two great groups :—

Classification.

Fuzzy-seeded and *Naked-seeded*.—As already observed, a classification exclusively based on any one structural peculiarity would of necessity be misleading, more especially if the selected character could be shown, as in the present instance, to be very largely a special adaptation to external and variable conditions. The grouping suggested is of value, however, when viewed carefully in conjunction with the assemblage of other characteristics that may be said to demarcate the species. It is, moreover, a simple and convenient method of recognising the more important New World cottons.

Selection.

It may be recollected that the seeds of most wild cottons contain a more or less complete coating of hairs, formed, it is believed, with a view to protection from insect enemies. Certain developments of that feature may, therefore, be regarded as brought into existence primarily as a consequence of definite adaptations, but by human selection these have been fostered or changed in accordance with an altogether new purpose, namely the supply of fibre of a particular length, strength or colour. In some instances, a proportion only of the coating has been elongated, either naturally or as a direct consequence of cultivation. Hence it has come about that the coating of hairs may be referable to two layers—an under coating of short hairs (the fuzz), and an outer coating (the floss). But, on the other hand, the whole of the coating may elongate into floss, the seeds in such cases being described as "*naked*," that is to say, not possessed of a fuzz. Lastly, the elongation of the floss may not be constant or uniform; a certain proportion may be shorter than the rest. Want of uniformity in the length of the staple is a serious defect, hence in selection of stock this aspect has to be carefully considered. But now comes a curious circumstance, and one of great practical interest: seeds possessed of a fuzz have, as a rule,

Fuzzy and
Naked Seeds.

their floss more securely and firmly bound to the seed-coat than is the case with naked seeds. This has led to two classes of gins, namely saw-gins and roller-gins, the former being regarded as necessary to tear the firmly bound fibre from the seed-coat, and the latter sufficient for the naked-seeded cottons. The tearing of the staple is a significant feature that lowers very materially the value of the floss, apart altogether from other considerations. A naked-seeded readily separable floss is, therefore, a high qualification, and one that marks great progression in cotton cultivation.

Necessity for
two Kinds of
Gins.
Tearing of
Staple.

Fuzzy-seeded Cottons of the New World.—The species that fall into this position are:—

G. hirsutum, Linn., *Sp. Pl.* (non Herb. and non Syst. Nat.), 2nd ed., 1763, 975, founded on Miller, *Gard. Dict.*, 7th ed., 1759, n. 4; *G. latifolium*, Murray, *Comm. Soc. Reg. Gott.*, 1776, vii., 22-5, t. 1; Watt, *l.c.* 183-200, tt. 29-31. This is possibly a cultivated state of *G. punctatum*, Sch. et Thon. (*G. jamaicense*, Macf.).

D. P.,
iv., 17-
aw-ginned
Dharwar.

A botanical specimen contributed by Philip Miller is preserved in the British Museum and is, therefore, very possibly the actual type of the species. Another specimen of the same plant will be found in the Badminton Garden herbarium (also preserved in the British Museum), which was very probably the source from whence Miller obtained seed. And it is just possible the Badminton stock came from Guadeloupe Island, having been contributed by the brothers Lignon, mentioned by Tournefort as having sent seeds of West Indian plants, more especially from Guadeloupe, to Paris. It is interesting, therefore, to be able to add that the record exists of seed having been grown in Georgia in 1734, from a supply furnished by Miller from the Chelsea Physic Garden. There is thus little doubt that the introduction of the actual stock of the New Orleans, Georgian, and many other short-staple American cottons, dates very possibly from the supply sent out by Miller. But to this same plant has to be attributed the Egyptian (Delta lands) cotton—a plant that existed very possibly in Upper Egypt long anterior to the modern traffic, the stock of which we know came very largely from the United States of America. So also the so-called saw-ginned Dharwar cottons of recent Indian commerce were obtained from the States, though later supplies were procured from Egypt, from belief that they represented a special and peculiar plant known in trade as "Egyptian Cotton."

Miller's Chelsea
Stock.

Grown in
Georgia.

Some years previous to this historic introduction of the Dharwar stock, Roxburgh spoke of the plant having been only of late brought into India. He does not tell us where it came from, but his description occasions no doubt as to its determination, and he was the first botanist to affirm that the seeds were free from each other. Interest was being taken in the plant the world over, however, since towards the close of the 18th century Murray furnished an admirable picture and description of it, under the name *G. latifolium*. During the past fifty or sixty years the cultivation of this cotton in India has gradually concentrated in the Deccan. It is, of course, also met with in other parts of India, but success has chiefly attended its acclimatisation in Dharwar and the neighbouring districts, hence its being known in trade as Saw-ginned Dharwar.

Cultivation in
India.

In 1894 I made a tour on foot through certain districts of the Central Provinces and Berar, in order to study in the field the cottons there cultivated. In many parts of Nagpur, Wardha, Ellichpur, Amraoti and Akola I found the present plant very largely mixed in all the fields of the so-called higher grade "*Oomras*." In many cases it would not have been an over-estimate to say that they contained from 20 to 30 per cent. of *G. hirsutum*, the balance being *G. Nanking*, var. *ant*, of an inferior stock for the most part. The latter was a much larger and more prolific yielder, and the former was grown, so the cultivators told me, entirely because the mixture was believed to raise the grade of the staple. Except, therefore, in Dharwar, where it is grown a pure crop, the condition mentioned as discovered in the Central Provinces is characteristic of the occurrence of the present plant in India as a whole. It has, however, greatly degenerated, and is often not more than a foot or a foot and a half in height; is a coarse, stunted, much-branched, erect, greenish-red, dust-coated bush, the last-mentioned peculiarity being a consequence of the abundance, length and strength of the hairs with which the shoots, leaf-stalks and veins are coated. The seeds are always large, ovate, truncated on one extremity and have a strong dense fuzz, which may be grey or green in colour. The floss

Admixture.

General
Appearance.

gyptian Cotton

adheres very firmly, hence necessitating the use of saw-gins, but it is fairly long and silky.

As met with in India, the plant has degenerated very greatly from the standard preserved in the United States and in Egypt—has, in fact, approached in many directions to the specific conditions of *G. punctatum*, although I am not aware of its ever having been recorded as met with as an escape from cultivation. Had systematic selection of stock been pursued in India, there is little doubt that a higher standard than exists might have been maintained, if not a progression secured. Of this there can be no doubt, that the Upland Cottons of America have advanced until the plant that now affords them is no longer *G. hirsutum*, but a greatly improved stock that botanically might be described as a hybrid between *G. hirsutum* and *G. mexicanum*.

eligious
Cotton.

Var. religiosa, Watt, l.c. 201-4, tt. 32, 33; *G. religiosum*, Linn., *Syst. Nat.*, 1767, ii., 462 (in part); *G. religiosum*, Linn. *Herb.*; *G. tricuspidatum*, Lamk., *Encycl.*, ii., 135; *G. croceum*, Ham., *Trans. Linn. Soc.*, 1822, xiii., 491-4; *G. religiosum*, Rozb., *Fl. Ind.*, 1832, iii., 185-6, but MS. drawing n. 1497 is named *G. fuscum*.

This somewhat remarkable plant is mentioned here mainly in order to allow of its separation from *G. brasiliense* (which by Parlatore and others has been incorrectly called *G. religiosum*). It is not of much importance commercially as its separation from *G. hirsutum* is a matter of great difficulty, and, moreover, the plant does not appear to be very extensively cultivated. It is best distinguished from the normal condition of saw-ginned Dharwar cotton by its trailing habit and more softly hairy condition. The lateral shoots are much elongated and slender and the internodes are long, straight and profusely tomentose. It is not uncommon to find popular writers in India affirming that the name *religiosum* was given to denote a cotton cultivated by mendicants or one met with near temples. The name was first used by Linnæus, and there is no proof whatever that his specimen came from India. Moreover, the plant that in India might deserve the name *religiosum* would be the *deo kâpas* or *ram-kâpas*, which is *G. arboreum*. Roxburgh was the first botanist who critically studied the plant, and he came to the very correct conclusion that it could "scarcely be more than a variety of *hirsutum*."

Red
Peruvian.

G. ieroc r, Tod., *Hort. Bot. Pan.*, 1876, i., 63, t. 14; Watt, l.c. 210-3, t. 36; *Nigro Cotton*, Labat, *Nouv. Rel. de l'Afrique Occ.*, 1728, iii., 262-9, t. 261.

A remarkable plant met with now and again throughout the cotton areas, more especially in Africa, though the type was described from a plant raised (so Todaro says) from seed procured from Mexico. Its leaves are even more deeply palmisected—the lobes being almost linear—than is the case with *G. brasiliense*, but they are in addition pilose-tomentose, while the seeds are semi-conglomerated and partially coated with a velvet. One of the most striking peculiarities of this plant is the immense size of the calyx. By most writers this has been confused with kidney cotton (*G. brasiliense*), but others call it the true Pernambuco cotton of commerce, which they hold to be thus distinct from the kidney cotton. By still others it is the original stock of the *ashmouni* cotton of Egypt, an opinion which I do not accept. Perhaps its best popular name is Red Peruvian.

er vi, Cav., *Diss.*, 1785-90, 313, t. 168; *G. vitifolium*, Rozb., *Fl. Ind.*, iii., 186; ? *G. religiosum*, Parl. (in part, but non Linn.); *G. hirsutum*, Cook, *Weevil Resist. Adapt. of Cot. Pl.*; Watt, l.c. 213-26, tt. 37, 38. *U.S. Dept. Agri. Pl. Indust. Bull.*, 1906, No. 88, 8. Possibly indigenous to Central and South America; is the so-called Peruvian Cotton now met with in most cotton-growing countries, especially West Africa, where it received numerous distinctive local names, such as *owu* of Abbeokuta and *ukoko* of the Congo; and most of the races of ordinary or short-staple Egyptians, such as the *Ashmouni*, *Mit Afifi*, *Zafiri* and *Abassi*.

This somewhat obscure species links together *G. mexicanum* and *G. brasiliense*. It has the palmisected foliage of the latter with the blistering habit of twigs and fuzz-coated seeds of the former. It is somewhat significant that

all the American and African cultivated cottons that possess seeds more or less coated with a velvet or fuzz (e.g. *G. hirsutum*, *G. mexicanum* and *G. peruvianum*) have the leaves more or less pilose, while the forms with sub-glabrous leaves (e.g. *G. purpurascens*, *G. vitifolium* and *G. brasiliense*) have the seeds practically naked; that is to say, they do not possess a fuzz.

G. exic, *Tod., Relaz. Cult. dei Cot.*, 193, tt. vi., xii., f. 32; Upland and Watt, *l.c.* 226-44, tt. 39-42. This hybrid species is often very difficult to separate from *G. purpurascens* when in foliage. The leaves are broad, smooth, glabrescent with five to seven radiating veins and lobes; peduncles prolonged, pedicels short and flowers small, pale-coloured, nodding; seeds large, with thin ashy fuzz, and copious woolly floss. Apparently originally procured from Mexico, but so far as known is met with under cultivation only.

Roxburgh tells us that this was introduced into India by W. Hamilton in 1804, but subsequently he seems to have confused it with Bourbon Cotton (*G. purpurascens*), and gave both plants the botanical name of *G. barbadense*, Willd., since both his MS. drawings (so named) are in reality *G. mexicanum*. He further apparently alludes to this plant under *G. hirsutum* as being grey-seeded. Wight, Spry and many other Indian writers refer to Mexican Cotton in the Journals of the Agri.-Horticultural Society.

It has, however, to be admitted that some uncertainty exists as to the plant Todaro actually meant by the name *G. mexicanum*. If his coloured illustration be accepted arbitrarily as the type, then it has to be confessed that it is not very plentiful in herbaria. In all the samples seen by me that approach most closely to that type, the plants either came from Mexico or were raised from seed procured from that country, as Todaro affirms was the case with the plant figured and described by him. But in all the best tracts of America, from which the finest Upland and Georgian Cottons are procured, the plant there grown is almost exactly intermediate between the type of *G. hirsutum* and that of *G. m. exic*. The leaves are large and broad in fully-formed conditions, are 5-, sometimes even 7-lobed or only angled. In texture they are smooth, thick, leathery and either very hairy (in forms that approach to *G. hirsutum*) or almost quite glabrous (in those with a closer approximation to *G. mexicanum*). In the United States fresh stock has again and again been imported from Mexico, and the admission made that the previously existing stocks had been thereby much improved. There would thus seem little doubt that the improvement that has been consistently reported as taking place has run parallel with an undoubted advancement from the older type of *G. hirsutum* towards that which more appropriately should (from the botanical standpoint) be designated *G. mexicanum*. But they are one and all hybrids, and the suggestion may be offered that they have been derived from *G. hirsutum* as the one stock, and either *G. purpurascens* or *G. vitifolium* (*G. barbadense*) the other—the result being the presumed hybrid condition here designated *G. mexicanum*. Of the more famed cottons of this assemblage, the following may be specially mentioned as (a) hairy (e.g. aff. *G. hirsutum*) forms:—“Allen,” “Peeler,” “Sunflower,” “Todd” and “Russell.” Of the (b) glabrous (aff. *G. mexicanum*):—“Welbo’s Pet,” “Willet’s Red Leaf,” “Parker,” “Layton’s Improved,” “Toale,” “Shine,” “Simms,” “Berry’s Big Boll,” “Culpepper,” “Cummings,” “Triumph,” “Gibson,” “Myers” and “Texas Wool.” Reversions are also recorded, one example of which may be here specially mentioned, namely “King’s Improved,” which comes closer to *G. punctatum* than to the bulk of the modern *G. mexicanum* cottons that to-day are called by the old, but now hardly accurate name of *G. hirsutum*. Another illustration is the tendency for green-seeded stock (*G. hirsutum* type proper) to produce brown or grey-seeded forms (*G. mexicanum*) according as the degree of cultivation or neglect tends to develop and establish the one or other ancestor of the present-day much hybridised stock of Upland cottons.

Naked-seeded Cottons of the New World.—The following, among other species, may be specially mentioned in this position:—

G. r r ce, *Poir., Lamk., Encycl. Meth. Bot. suppl.*, 1811, Bourbon ii., 369; Watt, *l.c.* 250-5, t. 44. A cultivated perennial plant of which Cotton.

there are several distinctive races, derived very possibly from *G. taitense*, *Parl.*, and which constitute the Bourbon and Porto Rico Cottons of commerce.

The seeds are not only what is called naked, but the leaves are almost glabrous. They are perennial plants with strongly angled purplish shoots and leaves ovate entire or with three lobes on the apex, the laterals arching outwards and the petioles almost thorny through the growth of glandular warts. They are all essentially insular plants, hence the greater success attained with them in South as compared with North India. They seem to be readily hybridised, and in consequence it is not uncommon for completely fuzzy seeds to appear among plants raised from the normal condition, viz. the seeds naked, except for a tuft of rust-coloured fuzz around the beak.

Vine-
leaved
Cotton.

G. vitifoli, *Lamk., Encycl. Meth. Bot.*, ii., 135 (excl. syn. *Pluk. Alm.*, t. 188, f. 2, added doubtfully by *Lamk.*); *Watt, l.c.* 255-65, tt. 1, 45; *Xylon arboreum*, *Merian, Surin. Insect.*, 1679, t. 10; *Labat, Nouv. Voy. aux Isles de l'Amer.*, 1724, i., pt. 2, 125-31; *G. latifolium*, *Rumphius, Herb. Amb.*, 1750, iv., 37, t. xiii. (excl. syn.); *G. barbadense, Parl., Sp. dei Cot.*, t. iii. (in part); *G. religiosum, Aliotta, Riv. Crit. Gen. Goss.*, 44 (in part).

Long Staple,
Egyptian.

The Vine-leaved Cotton was probably originally a native of Central and South America, to the Amazon basin and the Lesser Antilles, but early found under cultivation throughout the cotton area of the world. It is the Egyptian long staple, Antilles, Piura, Surinam and Cayenne, St. Domingo, Guadeloupe, Barbados and other cottons. In the early literature of this genus the greatest possible obscurity prevails regarding *G. barbadense*. It might, in fact, without fear of contradiction, be affirmed that there was little or no distinction between that species and the present plant. As time advanced the form known as Sea Island Cotton appeared, and to it became restricted, by most authors, the name *G. barbadense*, leaving *G. vitifolium* to be accepted as denoting the slightly lower-grade cottons of South America and Egypt that are classed as "Long Staples." It is, in other words, highly likely that this plant may have been one of the ancestral stocks of *G. barbadense, var. maritima*—a plant which is perhaps the most recent addition to the prized races of cotton met with in the world. No one seems to know what was meant originally by *G. barbadense*. It nowhere exists in a wild state, and is apparently never cultivated except in the form nowadays called Sea Island, but which could hardly be accepted as *G. barbadense, Linn.* The present plant, on the other hand, exists in numerous forms. It is the vine-leaved cotton of most of the early authors, who repeatedly speak of it as met with wild or completely acclimatised. The leaves are sub-cordate with mostly only three ascending lobes, the texture often pilose-tomentose below. The bracteoles are very large, ovate rotund, deeply auricled, slightly united below and often possessed of the bractlets described by Cook as weevil-resisting adaptations (*U.S. Dept. Agri. Bureau Pl. Indust.*, 1906, No. 88.) Seeds black, naked and quite free from each other.

Weevil
R tent.

D. P.,
iv., 1 - O.
ea Island
Cotton.

G. barbadense, *Linn., Hort. Upsal.*, 1748, i., 204; *Sp. Pl.* (1st ed.), 1753, ii., 693; *Pluk., Alm. Bot.*, 1696, ii., 172, and *Phyt.*, t. 188, f. 1. (excl. all syn.); *Wight, Illust. Ind. Bot.*, 1840, i., 57-64, t. 28B; *Watt, l.c.* 265-95, tt. 46-8; Sea Island Cotton.

This embraces all the higher-grade long-staple cottons. A shrubby perennial known only in a state of cultivation, and raised usually as an annual. It is glabrous or nearly so, except on the leaf-stalks and veins and the under-surfaces of young leaves.

As already suggested, there seems every probability that the early authors who accepted the name *G. barbadense* did not realise that it meant one and the same plant as that designated *G. vitifolium*. By cultivation and crossing, however, a highly specialised race, known as "Sea Island," was produced, to which by recent authors the Linnean name *G. barbadense* became in time restricted, though *Todaro*, and following him some other botanists, preferred to give the new stock the name of *G. maritimum*, thus leaving *G. barbadense*

as a name for a species presumed by many to exist, but known for certain to no botanical writer. The species founded by Linnaeus may be said to turn on a specimen still preserved in the British Museum, and that specimen certainly agrees more closely with *G. vitifolium*, Lamk., than with the modern Sea Island Cotton of America.

Although repeatedly introduced into India, Sea Island Cotton has, in no locality, proved a success. It is possible, however, that it might be raised profitably in the Andaman and Nicobar Islands and in some parts of Tenasserim.

Ind.*, 1832, iii., 186 and MS. drawing n. 1598 (wrongly named *G. vitifolium*), etc., etc.

D. .P.,
iv., 23-5.
Kidney
Cotton.

The Chain, Kidney, Brazilian, Bahia, Pernambuco and Costa Rica Cottons of most popular writers, and in Burma it is *thembanwa* (ship's cotton). It was first definitely alluded to by John Leriuis, who lived in Brazil in 1557, and wrote a history of that country. Sir Walter Elliot, speaking of the plant as known to him in South India, calls it *paidi* (gold) *patti* and *pamidi patti* (the wealth-giving), names that denote the high expectations that were at one time entertained regarding this plant. It was apparently the first of the long-staple silky cottons of the New World to attract attention. Seeds were conveyed by Marcgraf and others, and the chain condition so well figured by Zanoni seems to have been accepted as a peculiarity of all cottons, hence Lobel (1576) thought he improved on the pictures of *G. herbaceum*, given thirty years previously by Fuchsius and Matthioli, by adding a kidneyed mass of seven seeds.

Chain Cotton.

All the nations of the world seem for a time to have vied with each other in the attempt to acclimatise the Brazilian Cotton, and in each new country to which taken it obtained the name of the region from whence immediately conveyed; accordingly in Burma, and also in the Antilles, it is called "Siam Cotton," and in India "Ava Cotton," etc. Roxburgh tells us in the MS. edition of his *Flora Indica* (preserved in Kew) that he became acquainted with it through seed sent him from Farukhabad. Mr. H. St. George Tucker (Member of the Court of Directors of the East India Company) observes that Lady Hastings grew it at Fatteghar, and Roger Hunt, in 1808, addressed the East India Company on the causes of deterioration of Pernambuco and Surinam Cottons. Thus we know that prior to Roxburgh's knowledge of it this plant had been experimentally tried in many parts of India.

Introduction to
India.

It is, therefore, perhaps not to be wondered at that this cotton has got considerably more widely distributed and is moreover more frequently met with in states of acclimatisation than is the case with any of the other New World cottons. Its large capsule, compact mass of seeds and the copious coating of floss naturally conveyed the impression of great value, and false expectations were raised, only to be rudely dispelled by comparisons of yield to acre. Gradually, however, all interest (or nearly so) in this particular Brazilian Cotton died out with the appearance first of the Upland Georgian Cottons, then the Mexican Cottons, and finally the Sea Island Cottons, all races that could be raised as annuals and occupy the soil for short periods. The present species in most countries accordingly fell into a state of complete neglect and either disappeared or survived as an escape from cultivation and became "the wild tree cotton" of most popular writers, the properties of which have been the will-o'-the-wisp of nearly each decade for the past century in the world's cotton are.

Wide
Distribution.

If I am correct in believing that this plant, however, represents an important stage in the development of the fine long staples of the West Indies and the Sea Islands of America, it is not by any means devoid of interest to persons interested in the production of new and improved races. But as met with in India to-day it is of no value whatever, and the expectations recently advanced regarding it would accordingly seem almost for certain doomed to disappointment, since opposed to all past experience with the plant. It may be said to have attained commercial importance within very restricted areas. In South America—its indigenous habitat—it is regarded as of special value because of its resistance of the diseases that prove disastrous to other cottons. In Guatemala, for example, it is believed to be immune from weevil.

Great
Expectations.

I. ADULTERATION AND DETERIORATION.—Milburn (*Or. Comm.*, 1813, 279–80) urged that it was impossible to be too attentive to the shipping of perfectly clean cotton. The adulteration and deterioration of Indian cotton has thus engaged attention for fully a century. St. George Tucker (to whom reference has been made above) wrote in 1830 a report *On the Supply of Cotton from British India* (*cf Reports on Cotton, Silk, and Indigo* published by the Company in 1836, 152–75) in order to account for its depression in price and deterioration in quality. He gives ten reasons. Royle (*Cult. and Comm. of Cotton in Ind.*, 1851, 551) deals frequently and effectively with this question. “When the cotton,” he says, which the Native grows, “is intended for sale, the *ryots* have little enough encouragement to bestow more care, either in growing or in picking their cotton, for they usually get no better price for a good and clean, than they do for an indifferent article.” So again, “Indian cotton is, however, from the shortness of staple, not well suited for all the purposes of the English manufacturer; but it is much more depreciated than it need be from the dirty and adulterated state in which it is sent to market.” Mention has been made that (about the time of the great cotton famine, 1861–5) notice was forcibly directed to India as a future country of supply for England. An outcry was shortly after made against the adulteration and mixing of inferior with superior grade staples. This led to the passing of the Cotton Frauds Act (IX. of 1863, and the Amendment of 1878, Act VII.).

Little
Encouragement
to Improve.

Cotton Frauds
Act of 1863.

Adulteration.

W. B. Wishart (Secretary of the Chamber of Commerce of Upper India) published in 1891 a *Note on the Adulteration of Cotton* in which he shows that the subject had agitated the minds of the cotton merchants of India for many years. He points out that a report issued in 1845, for example, gave details of the deterioration and decrease in outturn even then observed. Wishart then remarks: “There is now no *bona fide* market for our inferior cotton. Native hand-weavers cannot work it; the Chinese found out, some years ago, that it did not pay them to use it, and now our Continental customers can and do buy an article that suits them equally well at a proportionately lower price. There is, therefore, no outlet for such cottons, and Native growers and buyers have naturally taken to assisting each other by bulking the inferior and better stuff produced in each district, the mixture constituting a quality just a little below that which spinners want.”

In August 1891 a conference was held in the office of the Director of Land Records and Agriculture, Poona, at which proposals were made with a view to preserve and improve the quality of Indian cotton. In the same year Sir E. M. James (at that time Commissioner in Sind) drew up a Memorandum on Cotton. This was widely circulated by the Bombay Government, and elicited many valuable opinions and reports. The Chamber of Commerce of Bombay, for example, issued a very powerful reply, dated November 11, which fully expressed the opinion ultimately upheld by the Government, namely that while there was much need for effort at improving the stock, penal legislation was undesirable. Ten years later (Feb. 1901) the Hon. Mr. Bomanjee Petit (himself a prominent mill owner) pressed on the attention, both of the Bombay Government and the Mill Owners' Association, the serious consequences of the deterioration of the Indian cotton staple. It has now actually come about that both China and Japan have begun to produce coarse yarns of their own, and

Legislation
deemed
Undesirable.

have thus commenced to close two of the most important outlets for Indian exports. In consequence the necessity to advance has been borne home on the minds of the Indian mill owners. Instead of spinning as their finest yarns 20's, they have begun to think of 80's, but for this purpose they require to import raw cotton from Egypt, if not even from America. India no longer possesses a cotton suited for that purpose, and the adulteration and mixing of the staple have thus very nearly paralysed the industry. In consequence the outcry for legislation has once more been raised: it has been urged that a law requiring the locality of production to be stamped on all bales of cotton would have a highly beneficial result. Others look to the expectations of Sind, irrigated by a system of canals that may allow of the production of the high-grade Egyptian cottons, as the most hopeful indication of the future.

Necessity to Advance.

Recommendation for declaration of Locality.

Thus history repeats itself, in no commodity of commerce with greater regularity than in the theories and practices of cotton growing and cotton trading. One lesson alone seems to stand out through the past decades of the steam-power cotton industry of India as unwavering, viz. the conviction that when the time comes for India to assume once more the rôle of a producing and even exporting country in the finer cotton goods, it must either have improved its staple or discovered a country capable of meeting its necessities in suitable raw fibre. A low-grade staple such as the bulk of that grown in India to-day is utterly unsuited for the higher class machine-made goods, even were it put down at the mills pure and clean at a price below that procurable by any other power mills in the world. Thus it has been shown that cheap production is not necessarily economic production. Expensive labour means higher intelligence, with compensation in quality and price. O. P. Austin (*Cotton Trade of the United States*, 1900, 2608) points out, and with much force, that the low wages of the Indian cultivator are no real economy, since they prevent cotton cultivation on a large scale directed by intelligent supervision. Retrograde agriculture, such as has characterised the Indian cotton trade for a century past, must in the end fall behind in the race for commercial supremacy.

History repeats Itself.

Retrograde Agriculture.

II. IMPROVEMENT OF STOCK.—The cultivated cottons of the world have been referred to three great areas—(a) Asia, (b) Africa, and (c) America. But it has sometimes been affirmed that the first two can be taken together and spoken of as the fuzzy-seeded Asiatic and the others as the naked-seeded American cottons. But it is not the case that all the fuzzy-seeded species are Asiatic, any more than that all the naked-seeded are American. Moreover, the seeds of wild cottons have either a firmly adhering coating of wool or a readily separable floss. But there are both wild and cultivated cottons that possess both a fuzz and a floss. As already mentioned, Cook (*U.S. Dept. Agri. Bull.*, 1906, No. 88) thinks the wool may be a necessity in the protection of the seed from the enemies of the plant. Certainly in most wild forms, such as *G. Stocksii*, and still more so *G. Davidsonii*, the wool is so firmly and intricately crumpled up around the seed as to prove a veritable proboscis-proof protection, thus causing such seeds to be described as naked, the compacted fuzz having escaped detection. But of purely wild species the following among others possess a short velvety coating around the seed:—*G. Harknessii* (a native of California); *G. Palmerii* (of Mexico); *G. Sturtii* (of Australia), and *G. tomentosum* (of the Hawaiian Islands). On the other hand, the following have naked seeds:—*G. Kirkii* (of East Tropical

Fuzzy and Naked Seeds.

Africa), and *G. taitense* (of the Polynesian Islands). In passing it may be here added that no Asiatic indigenous cotton has a naked seed, and further that with the fuzzy-seeded Asiatic forms the bracteoles are united below, whereas with the American fuzzy-seeded cottons the bracteoles are free. The appearance, therefore, of these peculiarities in certain cultivated or long acclimatised plants may safely be regarded as denoting definite influences and not accidental sports or climatic adaptations.

pecific
influences.

ybridisation.

It has sometimes been upheld, but with little justification, that the crossing of fuzzy-seeded and naked-seeded cottons (or of Asiatic and American cottons) was impossible. But there is perhaps no subject on which greater diversity of opinion exists than in the value or even possibility of hybridisation of the species of *Gossypium*. One set of writers affirms that it is difficult, if not impossible, to prevent hybridisation, while another stoutly upholds the belief that hybridisation is of no practical value, if they do not indeed go so far as to deny the possibility of its accomplishment in nature. A parallel to this diversity (and perhaps a consequent one) is the degree of acceptance of the species as established by botanists. Some writers, such as Todaro, think there may be as many as 54 species, while others, such as Parlatore, reduce them to 7, and Aliotta to 5 species, with numerous varieties and cultivated races or hybrids under each. Buchanan-Hamilton went further and reduced all to 2 (or perhaps 3) species, viz. the black (naked) seeded and the white (fuzzy) seeded, with as a third the red (*kakhi*) seeded cottons. In fact the controversy regarding the number of species dates even from before the formation botanically of the genus *Gossypium*, but I venture to think it could never have existed and cannot exist to-day, when the undoubted wild forms are made the basis of classification.

umber of
pecies.

The confliction as to hybrids may be exemplified by the writings of two of the most recent authors. Aliotta (*Riv. Crit. Gen. Goss.* 1903) gives an elaborate statement of the races of cultivated cottons which he thinks have been produced through the cross-breeding of his five species—*G. barbadense*, *G. religiosum*, *G. arboreum*, *G. herbaceum*, and *G. hirsutum*. On the other hand, G. A. Gammie, Professor of Botany at Poona, Bombay, in his recent report (*The Indian Cottons*, 1905) reduces all the Indian cultivated forms to *G. obtusifolium*. He would, moreover, not appear to regard hybridisation as of any practical value whatever. He observes that the so-called species and hybrids are merely cultivated races evolved by time and environment from one prototype, but he nevertheless adds somewhat paradoxically that they are capable of being crossed with facility and that their descendants are fertile.

After many years of careful study of the Indian cottons, both in the field and the herbarium, I am constrained to join issue with Aliotta and writers of his school in thinking hybridisation has played an important rôle, though I am not of course prepared to reduce the ancestral stocks to five forms. Still I am satisfied that many of the more highly prized cultivated cottons are not species botanically (though it may be convenient to retain for them specific names), but are races and natural hybrids (some of the more recent artificial) adapted by selection to man's requirements and to environment. I am at one, in fact, with the army of workers in America who not only say they have produced endless forms by crossing, but who regard that agency as of the greatest possible importance. Tracey (Dabney, *The Cotton Plant*, 1896, 197-224), in dealing with the cultivated varieties, remarks, "Although the plants from a single line of crosses, as fertilising Peterkin with Allen, will vary widely, still it is a general

American
Hybrids.

rule that the character and habit of the future plant will be more like those of the female parent, while the fruit, the boll and its contents, will be more like those of the male parent." So again, "The tendency of the plant to vary from the typical form of any variety will be back towards its original form rather than in any other direction." From these and such-like considerations is doubtless due the affirmation that, from one or two plants specially cultivated and as a consequence of careful selection of sports, it might be possible to produce all the chief types of cultivated cottons. Hence it may be said that with few other cultivated plants is a more rigid selection of seed necessary than with cotton. Moreover, there seems little doubt but that historically it can be shown that *G. hirsutum*, *G. mexicanum*, *G. vitifolium* and *G. barbadense*, as known to us to-day, are themselves to a large extent hybrid stocks. It does not follow, however, that all hybrids may be fertile, still less that they can be invariably again further hybridised with fresh ancestral influences, according to the fancy of the operator. To the neglect of this consideration may be due much of past failure in hybridisation.

Tendencies of
Variation.

Selection.

One of the most valuable and interesting papers on this subject is that written by Austin Cannon, entitled *Spermatogenesis of Hybrid Cotton* (in *Bull. Torrey Bot. Club*, 1903, xxx., 133-72.) The cotton hybrid experimented on was produced (so we are told) between Sea Island Cotton (Constellation brand) and Upland Cotton (Klondike brand)—*G. barbadense* x *G. herbaceum* and the hybrids were found fertile. It is, however, just possible that the plant spoken of as *G. herbaceum* should have been called *G. hirsutum* or *G. mexicanum*, for until about 1896 Uplands were by American authors mostly spoken of under the botanical name that more properly belongs to the Mediterranean stock. All fuzzy-seeded cottons were often, in fact, regarded as one and the same species. It follows that to secure uniformity and precision in the laboratory and in the experimental farm, the foremost consideration must be the ascertainment of the species botanically that it is intended to investigate. Until such knowledge has been obtained it would be preferable to adopt some arbitrary nomenclature such as a numerical system, e.g. the "K2" of geographers, rather than to employ a misleading jargon of botanical names.

Spermatogenesis.

As a historic fact in Indian hybridisation it may be mentioned that in 1844 Mr. Alex. Burns of Broach crossed *G. obtusifolium*, var. *Wightiana*, with *G. arboreum*. He obtained a plant that had all the good points of both parents. The leaves were those of *arboreum*, only larger and more hairy, and the flowers were red with a yellow ring in the throat. This interesting new form, an undoubted hybrid, yielded its crop within a period of two months, much as in Broach *desht*, and the floss was very silky. The Bombay Chamber of Commerce expressed the opinion that the cross was an exceedingly valuable one. No further information was, however, published regarding it, and the plant seems to have died out. The circumstance is mentioned to show that crosses are possible.

Indian Hybrids.

Under the orders of the Government of India much has been recently done to discover the soils suited for cotton generally, and many valuable experiments have been conducted with exotic forms. What would appear the foremost consideration has, however, until very recently been almost entirely neglected, namely the attempt to improve the indigenous or long acclimatised stocks. Royle, for example, repudiated with some warmth the opinion attributed to him, that the greatest attention should be given to the cotton of the country (*Cult. and Comm. of Cotton in India*, 1851, 544-5). For a good few years past I have uniformly urged, and I repeat that recommendation, namely, to make real progress it is imperative that an exhaustive and scientific investigation should be conducted—a sort of census taken—of the existing stocks, not only of India but of the world. The climatic and other causes which tend to preserve or destroy good or bad properties have to be thoroughly established. The influences of hybridisation have to be worked out on a scientific basis by testing the strength of strain, from this species or that, best suited to environment, the tendencies of cultivated forms recognised and systematic renewal of stock in each locality accepted as a solemn obligation.

Improvement of
Indigenous
Stock.

A few years ago I drew attention to the establishment of steam ginning factories, all over India, as having created a new danger, namely degrading equalisation of stock. Nowadays the cultivators over a wide area carry the produce of their fields to these factories: all are mixed together, and seed returned to the cultivators that in many cases may be utterly unsuited to the fields on which it has to be grown. The specialisation of centuries of natural selection is thus being

Effect of Steam
G.

rapidly effaced by this new phase of commercial production. It has been found useless to urge that the cultivators should reserve their own supplies of seed. They are too poor and too ignorant to do so, and, moreover, are only too frequently in the hands of the money-lenders. (See Ginning, pp. 611-2.)

Short Staples.

Advantages of

Substitution.

Dacca
Cotton.

Lastly another evil has crept gradually into the cotton traffic of India. England having adapted her machinery to the steadily improving staple of the United States, soon became unable to work up the short staples of India. But in Germany, Japan and India itself, special factories were built with the object of running for the lower-class goods and working up the world's supplies of short staple. The cultivators were accordingly told that they would get no more for a long than for a short staple. In every district there were both high-class and low-class staples. The former gave a lower yield, compensated for by a higher price. The new condition naturally dictated the universal substitution of the lower grades, and an agricultural degradation in consequence was carried across the country in a remarkably short space of time that may take a century to efface. An official correspondence dated July, 1903, contains a letter from one of the most influential European merchants of India, which puts the present position tersely by narrating the advantages of the *delati* or *jari* plant of the Central Provinces and Berar:—(a) It is an earlier crop, thus enabling the cultivator to get a quicker return; (b) it runs accordingly less risk of injury from early cold weather; (c) it is a hardier plant, less liable to disease or to deterioration from rain; (d) it gives a larger weight outturn of lint; (e) it comes into market cleaner than the other grades.

The feature of early ripening is most important. The annual cottons of India have often been spoken of as consisting of two kinds—those that take eight months to ripen, and those that reach maturity in about five months from sowing. The cottons found on a deep, moisture-retaining, black, loamy soil are of the first class. They are usually grown as pure crops, and the particular race met with is often remarkably uniform. The cottons of the second class occur on light soils; they are produced normally as mixed crops and manifest the greatest possible variability. The influence of rainfall, both quantity and season, is of vital importance. The vicinity of Bombay town and south of the Konkan, since it possesses double the rainfall of Broach, grows next to no cotton, even although the soil may be highly suitable. Localities, like much of South India, that have two rainy seasons possess two widely different cotton crops. It is very largely in adaptation to the conditions of soil and climate that certain cottons owe their superiority or the opposite. The substitution, for example, of inferior for superior grades has been primarily the result of the demand for that staple, but the change has to many cultivators been all the more acceptable that the plant required was in their locality hardier and less risky. Some twenty to thirty years ago the Central Provinces had a fair proportion of *bani* (superior cotton) relative to its *jari* (or inferior cotton). To-day the crop is mainly *jari*. The former could be spun into yarns of 20's and up even to 40's; the latter can rarely be used for more than counts up to 10's. The *bani* cottons were the once famed Ghat cottons, such as the Hinganghat of commerce. The *jari* has a very short staple, but is exceedingly hardy and prolific.

As manifesting the present position of cotton and its degeneration, as also some of the features of the programme of improvement that may be found imperatively necessary, the following jottings regarding the famed Dacca cotton may be usefully set forth:—In view of the efforts presently being made to develop the industry of cotton cultivation in Bengal, it seems desirable that the opinions of the earliest writers be briefly indicated. Mr. Bebb, Commercial Resident of Dacca, furnished a reply to an inquiry made by the East India Company, and that reply is one of the earliest accounts of Dacca (in fact of Bengal) cotton. It is dated 1788, and speaks of the staple as "the finest cotton in the world, producing cloth of astonishing beauty and fineness." The plant is said to have been an annual, and to have afforded two crops in the year, in April and again in September. The first was the most esteemed and obtained the highest price, but was liable to failure from long drought or from violent storms, though moderate showers were highly beneficial. In the volume of Reports on Cotton, Silk and Indigo published by the East India Company in 1836, there is a report written by St. George Tucker in 1829 (*Supply of Cotton from British India*, 159-60) in which he discusses the superior cotton of Dacca. He calls it *bairati kupa*—the finest variety perhaps of the Eastern cottons. It is produced only in small quantity, in the districts north-west of Dacca, and is never exported. Its favourite

site seems to be the high banks of the Ganges and its tributaries. The fibre of the *bairati* is extremely fine, silky and strong, but the staple is very short and the wool adheres most tenaciously to the seed. It is admirably calculated for the manufacture of the muslins and thinner fabrics. It is perhaps too costly a production to enter largely into our manufactures. Tucker then adds that the *bogha kupas* is the ordinary cotton staple of Bengal proper.

Roxburgh, who was appointed Superintendent of the Royal Botanic Gardens of Calcutta in 1793, early gave attention to this special Dacca cotton (Royle, *Cult. and Comm. Cotton*, 245). He gives, in his *Flora Indica*, the points of difference between the ordinary Bengal and the special Dacca cotton. The plant, he says, is more erect, has fewer branches, and the lobes of the leaves more pointed. The whole plant is tinged with red, even the petioles and nerves of the leaves, and it is less pubescent. The peduncles of the flowers are longer and the exterior margins of the petals are tinged with red. The staple is longer, much finer, and softer. Roxburgh's MS. plate of the plant thus distinguished is in the herbarium of the Royal Botanic Gardens, Calcutta (a copy of which is in Kew, and has been reproduced by me in the *Wild and Cultivated Cotton Plants of the World*, pl. 12). It manifests all the special peculiarities mentioned, and thus doubtless faithfully represents the plant; but Roxburgh adds that the people of Dacca think the great difference lies in the spinning and allow little for the influence of the soil. (See remarks on Hand-loom, p. 616.)

Dacca Cotton.

It has recently been affirmed that the cotton formerly used by the Dacca manufacturers, of the far-famed exceedingly fine muslins of that city, was derived from tree cottons. Further, that the loss of these special crops caused the decadence of the muslin industry. Taylor's account (*Topog. and Stat. Dacca*, 1840) would seem to give a complete refutation of that statement. Moreover, the question may be asked, "Is it or is it not a fact that with an exceedingly short staple the Dacca manufacturers are *still* producing (or until very recently were producing) muslins, which if not up to the old standards, are certainly far finer than could be manufactured from these staples by any process or machine known to Europe or America to-day?" Taylor says, "The material of which the fine Dacca muslins are made, is entirely the produce of the district. The plant is an annual one, and attains a height of about five feet. It is described by Roxburgh as a variety of the *G. herbaceum*, and is said to differ from the common cotton plant of Bengal in the following particulars: (1) The branches are more erect and fewer, and the lobes of the leaves more pointed. (2) The whole of the plant is tinged of a reddish colour, even the petioles and nerves of the leaves are less pubescent. (3) The peduncles, which support the flowers, are longer and the exterior margins of the petals are tinged with red. (4) The staple of the cotton is longer, much finer and softer." This is the *desi* or indigenous cotton of the district, which has been cultivated in the northern division from time immemorial.

Muslin Industry.

Differences.

"Formerly, when this article was more extensively cultivated than at present, there were different shades of quality observable in the staple, which either cannot now be distinguished or have degenerated into one of an inferior degree. They were known by the names of *Phootee*, *Nurmah* and *Bairaitte*. The cotton of the present day, it is affirmed by the Natives, is inferior to what it formerly was. The crops are less abundant; it is said that the fibres, though apparently equally fine and soft, are shorter and more firmly adherent to the seed, than the produce of former years. The Dacca cotton, however, notwithstanding the deterioration imputed to it, still ranks as an article of finer quality than the produce of other parts of Bengal or of the western provinces." . . . "The seeds, which are used for sowing, are carefully picked, and after having been dried in the sun are preserved in an earthen pot in which oil or *ghi* has been kept, and the vessel with its mouth stopped up, so as to exclude the external air, is hung up to the roof of the hut, and over the spot where the fire is usually kindled. The high lands are selected for this crop and are ploughed from eight to twelve times up to September and October when the seeds are sown. This is done in parallel rows, distant about a cubit from each other, and before the seeds are dropped into the ground they are moistened with water. The cotton plant is liable to injury from hail-storms, heavy rain and caterpillars." . . . "Formerly the ground for cotton was allowed to lie fallow every fourth year, and it appeared to be owing to the neglect of this circumstance in the present day, that the produce is now inferior in quality to that of former times."

Selection of Seed.

"The cotton of the northern division is said to swell less than the produce

of other parts of the country. This tendency of the fibre to swell in bleaching is the criterion by which the weavers judge of its quality, but whether it depends on any adherent property in the cotton itself, or on the water used in the bleaching is not known, though there is reason to believe that it is principally owing to the latter. The thread manufactured at Dumroy, which was reported by Mr. Bebb, the Commercial Resident, to swell the most, is found by the weavers at present to be equal to the thread of the best *aurungs* or to swell the least if bleached in Dacca, but the reverse, as Mr. Bebb describes it, if the water of Dumroy be used in the process."

Lastly, Sen (*Rept. Agri. Stat. Dacca*, 1889, 52) also says: "The cultivation is not now done half so carefully as was the case at the time of Dr. Taylor. The field is prepared by two to four ploughings and as many harrowings. Furrows are then drawn a cubit apart, and in these furrows cotton seeds previously moistened with dung-water are dropped in thickly. When the plants come out they are thinned to a distance of a foot from one another." (See *Cultivation in Bengal*, p. 607.)

Improvement.

Improvement, when seriously contemplated, will have to be undertaken, not at a great central farm for all India, but district by district. The establishment of seed farms for the supply of specially improved indigenous stock—a subject I had the pleasure of recommending to the consideration of the Scientific Board of Advice at their first meeting—is at present earnestly engaging the attention of the agricultural experts of the Government of India. It may, therefore, suffice by way of concluding this brief sketch of the present position and knowledge regarding the possible methods and results of improvement of cotton stock, to recapitulate the main ideas. Improvement is possible by (a) Selection of seed, in adaptation to environment and trade requirements; (b) Hybridisation, an additional agency to attain these objects; (c) Acclimatisation of prized foreign stocks. All three methods are in India receiving consideration at present. For many of the cotton districts, selection from existing stocks seems the most hopeful method. It may be said, however, that in the discovery of absolutely new stocks, hybridisation is often of special value.

Seed Farms.

Directions of Improvement.

Cotton Expert.

The Government of India have recently appointed an expert in charge of cotton experiments. The results so far attained in selection and crossing are admittedly of a tentative nature, but Gammie's first report (*Note on the Class. Ind. Cottons and Cross-breeding Exper.*, Poona Farm, 1901-2) manifests a useful start as accomplished. The endeavours of the Bombay Government to bring the vast tracts of Sind under Egyptian cotton through the supply of cheap canal water, would seem to have given much promise, and in the public press repeated mention has recently been made of the high prices realised for the cotton already produced. It may thus be confidently affirmed that there does not appear to be any sufficient reason for doubting the success likely to be attained in India than in other countries with the production of superior cottons. The only untoward anticipations centre around the willingness or ability of the Native cultivator to advance with the times. [*Cf. R. J. Redding, Essential Steps in Securing an Early Crop of Cotton*, in *U.S. Dept. Agri. Farmer's Bull.*, 1905, No. 217; *Testing Cotton Seed*, in *Agri. Journ. Ind.*, 1906, i., pt. ii., 174; also Sly, *Fumigation American Cotton Seed*, etc., 1907, ii., pt. ii., 212.]

D. P.,
iv., 0-4.
o bay.
Area and Yield.

Area and Production.—According to the official *Agricultural Statistics*, the total area under cotton for 1904-5 in the British districts was 3,605,985 acres. The most important localities were Khan-

desh, 1,201,673 acres ; Dharwar, 581,950 ; Bijapur, 455,864 ; Ahmedabad, 340,602 ; Broach, 274,699 ; Sind, 218,050 ; Belgaum, 183,207 ; Ahmednagar, 79,626. The area of cotton in the Native States of the Bombay Presidency is an important factor in the Indian cotton supply. This came in 1904-5 to 2,570,985 acres. Kathiawar has usually one to two million acres, and Baroda half a million acres under the crop. The Native States and British districts together thus show the Bombay Presidency with a cotton area of 6,176,970 acres in 1904-5. The yield for the same year was 893,000 bales of 400 lb., or 3,189,285 cwt. The estimated area and yield for the following year were 6,108,900 acres, yielding 1,117,000 bales, in Bombay (including Native States) ; and 265,000 acres, yielding 79,000 bales, in Sind (including Native States), giving totals of 6,373,900 acres and 1,196,000 bales. The *Final Memorandum* for the year 1906-7 gives a total of 3,995,499 acres for the British districts, including Sind, and of 3,462,854 acres for the Native States, a grand total of 7,458,353 acres. This estimate is said to be 49.9 per cent. in excess of the average of the preceding ten years. The estimated yield during the same year is 824,052 bales in the British districts (including Sind), 1,071,243 bales in the Native States. The total is thus 1,895,295 bales, an increase of 132.9 per cent. on the yield of the preceding ten years.

Kathiawar.

Area and
Production in
1906-7.

Traffic.—In order to arrive at some tangible conception of the local and foreign interests in the cotton of this Presidency, it may be useful to analyse production and supply in the light of the official returns of trade by rail and river and by sea coastwise, from and into town and Presidency. The most interesting features are the supplies drawn by the town from Kathiawar, from the Presidency of Bombay itself, from Berar and from the Central Provinces. The adjustment arrived at shows the Presidency in 1905-6 to make a net export of 2,765,696 cwt., and assuming this to be drawn exclusively from local production (viz. in 1905-6, 1,117,000 bales or 3,989,285 cwt.), a balance of 1,223,589 cwt. would be the net supply retained by the Presidency. It is not, of course, necessarily the case that all the actual exports of a tract of country are drawn from its own production : an error exists in all such calculations which is eliminated by dealing with the whole of India, and for a number of years, not one year. It is useful, however, to ignore such errors and to analyse the figures as they stand. Accordingly, the port town of Bombay is shown to have imported by (internal transactions) rail and by sea coastwise, 10,583,652 cwt., and to have exported by these routes 261,070 cwt., thus showing a net import of 10,322,582 cwt., and, adding the foreign imports, viz. 158,838 cwt., a total net supply of 10,481,420 cwt. The foreign exports (external transactions) came to 5,289,691 cwt., and thus there remained 5,191,729 cwt. as the supply for the Bombay town mills, or, adding the Presidency surplus (viz. 1,223,589 cwt.), 6,415,318 cwt. are shown as having been available for the Presidency and town of Bombay for the year in question. The town of Karachi imports by rail and river approximately the amount which appears in her foreign exports, viz. in 1905-6, 709,257 cwt. In 1905-6 the total imports by rail and river came to 799,721 cwt., of which the Panjáb supplied 427,485 cwt., Sind almost as much, and the balance came from Rajputana and the United Provinces.

Picking.

accepted as a summary. The soil of Broach district is deep and retentive of moisture, and over the greater part the annual rainfall exceeds 35 inches on an average. The crop is sown as soon as possible after the monsoon sets in, in June or July, but owing to the effect of the heavy rainfall, two or more sowings may be required before the seeds germinate satisfactorily. Usually the same field grows cotton every second year, and in intermediate years the ground may lie fallow or grow one of the ordinary rotation crops. Manure is rarely applied oftener than once in three years, and fifteen loads per acre is considered a full average. It should be thoroughly decayed and applied preferably before the rains.

Soils.—The crop thrives best on fairly deep black soil, with a rainfall of 30 to 40 inches, and it is grown entirely as a dry crop. The most suitable soil is the so-called "black cotton soil," which may be found in some parts to a depth of five feet or more as in Ahmedabad, Broach and Surat; but cotton also succeeds on much shallower soils.

Rotation.—Generally the crop is grown alone, but where the rainfall is heavy and the soil retentive as in Broach, rice in the same or in separate rows is often subordinate to it. *Coriander*, *Sesamum*, gram (*Cicer arietinum*) are sometimes sown to fill vacancies. The *roji* cotton of Kaira, etc., is, on sandy loam soils, always grown as a row crop with *bájra* (*Pennisetum typhoideum*) or pulses. The principal rotation crop with cotton is *juár* (*Sorghum vulgare*), but this may be modified according to district and season. Thus wheat is extensively grown as a dry *rabí* crop on the cotton soils of Ahmedabad, *láng* (*Lathyrus sativus*) and a mixed crop of *tuver* (*Cajanus indicus*) and *Sesamum* as *rabí* crops in Broach, etc.

Tillage.—Preparatory tilling begins usually in the hot weather by collecting and burning the stubble of the previous crop. Two ploughings and two more harrowings may be required before the seed is sown, but the amount of preparatory tillage necessary depends on the previous crop.

Seed.—The seeds require special preparation for sowing, as they generally cling together, owing to the lint and fuzz which may still adhere to them. This is accomplished by mixing them with a thin plaster of cowdung, mud and water, and rubbing the plastered seed on the close network of a Native bedstead. The seeds can then be passed through the seed-bowls and tubes of an ordinary country seed-drill. If sown alone the seed is drilled in rows 22 to 26 inches apart. About 15 lb. per acre is the usual seed rate. Two harrows follow one drill to cover the seed and smooth the surface. If the seedlings are damaged before they produce true leaves, the crop should be resown, if the season has not too far advanced.

When the seedlings are about 4 inches high, the crop is ordinarily intercultured with the bullock hoe and hand-weeded. The weaklings are then thinned out and the plants left about 18 inches to 2 feet apart, if in good condition, but if backward or stunted they are left closer together. The plough is finally passed between the rows in September or October.

Crop.—Flowering begins in October–November, and may last till January if the rains are late and favourable. Picking usually commences in January and lasts till March or April. The crop is picked at short intervals, as the cultivators are afraid of their fields being robbed at night. The best time for picking is the morning, as the lint is then clean, owing to the dew on the foliage.

DIFFERENT FORMS GROWN

**GO YPIUM
CULTIVATION
in ombay**

Yield and Cost.—According to Mollison, the average outturn of seed and cotton together in the Presidency varies from about 300 lb. per acre in the Karnatak to as high as 446 lb. in some well-cultivated fields in Broach. The proportion of clean to seed cotton is on an average about one to three. The total cost of cultivation per acre in the Surat district he estimates at Rs. 21-13 annas.

Modifications on above System.—In Surat the average rainfall is slightly heavier than in Broach, but the soil is not so deep nor so dense, and there is less risk of seedlings being destroyed by rain. The rotation crops are mostly *kharif*, whereas in Broach they are *rabi*. *Juar* is the principal rotation crop, always with a subordinate mixture of white *tuver*. Rice is never sown with cotton in Surat. Surat versus
Broach.

The principal variation in cultivation in the Karnatak is due to the monsoons—the south-west between June and October, and the north-east between October and December. If sowing were to take place in June, as in other districts, the Dharwar crop would ripen in the middle of the north-east monsoon and the cotton be damaged by rain. To prevent this, sowing usually takes place in the latter part of August, and may be even extended to September. The seedlings are not thinned out to the same extent as in Broach and Surat, but are left comparatively close together. Karnatak.

Dharwar.

In Khandesh two forms of cotton are grown, the one on black and the other on light soil; they generally occupy the same field once in three years. The light-soil crop yields best with heavy rainfall, the black-soil crop with moderate rainfall. The seed rate is 10 to 12 lb. per acre and is sown, if possible, by June. Picking begins in October and is complete in December. In cotton-picking, care should be taken to avoid floss which is discoloured and damaged by boll-worm, as such obtains a poorer price and its presence lowers the average rate obtained. Khandesh.

In selecting seed for next crop, care should be taken to secure bolls from the largest, healthiest and most copiously fruiting plants. Seed should not be taken from plants on which any of the bolls are affected by boll-worm. As a further precaution against boll-worm, cotton seed should, before it is prepared for sowing, be steeped for five minutes in a $\frac{1}{2}$ per cent. solution of copper sulphate and then dried in the sun. Disastrous effects on the cotton crop may be produced by sudden atmospheric disturbances. The most trying consequences are due to heavy rainfall, frequent changes of wind, cloudy weather and frost. An abstract from Mr. Walton's *History of Cotton in Bombay*, detailing the various diseases caused by these conditions, is given in the *Dictionary* (iv., 70). Seed Selection.

Washing the
Seed.

Atmospheric
Disturbances.

Exotic Cottons.—Except in the Karnatak, where an American cotton has been acclimatised, foreign cottons have failed to take any very prominent place. In this connection mention may be made of the attempts of the late Mr. Tata of Bombay to grow Egyptian cotton beyond the Ghats as a *rabi* crop in the eight months of dry weather that prevail between the monsoons. The result may be said to have been a failure. At Poona in 1900 two Egyptian cottons were tried. They had an unhealthy appearance from the first, many of the bolls dropped before they were ripe, and both together gave an average outturn of only 401 lb., lint and seed, per acre. Egyptian.

SIND.—Area and Production.—In the *Final Memorandum for 1906-7* Irri ation
Cotton.

Flooding.

on cotton-growing in India, issued by the Government, the total area in Sind and its Native States was 245,549 acres. The method of cultivation in Sind differs considerably from that pursued in Bombay. The rainfall is excessively small, and the greater part of the cotton is cultivated by irrigation. An unfailing supply of water can be procured from the Indus. Two methods of cultivation are employed. By the first, frequent watering is necessary after sowing, and the seed is sown on ridges in holes 18 inches apart, after the surface has been inundated. By the second, no watering after sowing is required. The only care necessary is to keep the earth about the stems loose and free from weeds.

Seasons.—In Upper Sind the crop is sown at the end of February or beginning of March, or sometimes as late as May or even June. Picking ordinarily takes place in July to August. After picking, cattle are turned on to the fields to graze, but the roots are left for a second year. Farm-yard manure is used, about 12 maunds to the *bigha*. In other parts of Sind cotton is not cultivated till the canals fill in June, and the crop consequently is not picked till November or December.

Egyptian.

Exotic Cottons.—Unlike Bombay, the experiments with Egyptian cottons would appear to have been successful. In a report on the experiments carried on at Dhoro Náro, dated August 30, 1904, Mr. F. Fletcher, then Deputy Director of Agriculture, said of *ashmouni* and *abassi* cottons that they yield a minimum of 1,500 lb. of seed-cotton per acre. The plants were irrigated every fifteen or twenty days, at the rate of about 380 cubic metres per acre. In his opinion the experiments so far conducted have sufficiently demonstrated that on perennially irrigated areas in Sind, the Egyptian cottons can be grown normally, and would presumably give even a large yield, but the proper time for sowing would be February or March, and not, as now practised, June to July. He further holds that over-irrigation is often practised on the Jamrás. The report then concludes that if the whole of Sind were put under perennial irrigation (through a dam constructed at Bukker) the potentialities of the province for cotton-growing could not be surpassed even by the United States. Mr. Fletcher's experience in Egypt gives an importance to his utterance on the question of cotton-growing in Sind that carries it to a higher platform than the sanguine expectations of many previous writers on Indian cotton-growing. The area under Egyptian cotton at present is 1,500 acres, but if Mr. Fletcher's expectations are even partially realised the future may witness a greatly increased interest in this subject, much to the advantage of India. [Cf. Watt, *l.c.* 225-6.]

2. CENTRAL PROVINCES AND BERAR.—Watt, *l.c.* 131-4.—**Area and Production.**—On an average of the five years ending 1904-5 the tract under cotton represented 23·60 per cent. of the total cotton area in British India. In 1904-5 there were 1,492,323 acres in the Central

PRODUCTION AND YIELD

**GO YPIU
CULTIVATI
C. Prov.**

Provinces and 3,069,024 acres in Berar. The comparative importance of the various districts may be gathered from the returns for the year named : CENTRAL PROVINCES—Wardha, 404,405 acres ; Nagpur, 404,411 ; Nimar, 298,387 ; Chhindwara, 113,780 ; BERAR—Amráoti, 715,127 ; Akola, 743,268 ; Wun, 478,211 ; Buldána, 421,768 ; Básim, 362,059 ; and Ellichpur, 348,591. The yield for the same year was 472,000 bales, or 1,692,857 cwt., in the Central Provinces ; 755,000 bales, or 2,696,428 cwt., in Berar. The estimated area and yield for the year following were 1,586,000 acres and 347,000 bales in the Central Provinces ; 3,197,900 acres and 483,000 bales in Berar ; giving totals of 4,783,900 acres and 830,000 bales. The final forecast for 1906-7 shows the total area for both the Central Provinces and Berar at 4,852,087 acres, or an increase of 45 per cent. on the decennial average. The yield for the same year is estimated at 880,984 bales, an increase of about 8 per cent. on the previous year.

Area and
Production in
1906-7.

Traffic.—Since 1903-4 the figures of railborne traffic have been returned for the Central Provinces and Berar conjointly, consequently 1903-4 is the last year in which they can be discussed separately. The Berar railborne traffic in 1903-4 shows a large export and insignificant import. The net exports in 1903-4 came to 2,049,881 cwt., by far the major portion going to the town of Bombay, the balance to Bengal Province (practically none to Calcutta), Bombay Presidency and the Central Provinces. A fairly large amount is usually shown exported in excess of local production, indicating possibly a considerable traffic by road that escapes registration. In the Central Provinces the net export amounted in 1903-4 to only 846,957 cwt., as compared with 2,049,881 cwt. in Berar. The difference is due chiefly to the large quantity the Central Provinces import, viz. 143,822 cwt. in 1903-4, far the largest part of which comes from Berar, Rajputana and Central India. Almost the whole of the exports go to the town of Bombay, an insignificant surplus going to the Presidency of Bombay and to Bengal. In 1905-6 the net exports from the Central Provinces and Berar together amounted to 4,229,617 cwt.

Inte 1 Trade.

Agricultural Operations.—**Rotation.**—In Berar, *tur* (*Cajanus indicus*), in the proportion of one-tenth, is generally associated with the cotton crop, but in the villages to the south and above the Ghats, *bajra* (*Pennisetum typhoideum*) and *tíl* (*Sesamum indicum*) sometimes replace it. Rotation is regarded as absolutely necessary. On light soils, cotton is usually rotated with *juar* only (*Sorghum vulgare*), but on the rich black soils of the plains, cotton, *juar* and a *rábí* crop are rotated alternately. A plurality of crops is generally grown in the third year, separate parts of the field being devoted to wheat, gram, linseed, or *lakh* (*Lathyrus sativus*), and these in their turn are also rotated. Preparatory ploughing is not carried out every year, as it is considered to impoverish the soil, unless manure be subsequently applied. The advantages of manure are thoroughly understood by the cultivators, but there is great difficulty in Berar in obtaining a supply. Poudrette is considered best, and cowdung comes next in order. Green soiling is sometimes, but very rarely, resorted to. Ploughing generally takes place in December or January, as soon as the crop of the year is removed. The fields are always cross-ploughed. Harrowing succeeds ploughing, and in the case of unploughed fields is the only preparatory operation.

Associated Crops.

Manures.

Ploughing.

Seed.—Sowing commences with the first fall of rain, in the early part of June. The seed of the previous year's crop is always used, and

Rainfall.

is prepared and sown much as in Bombay. Ten pounds of seed are considered sufficient for an acre of land. Should a period of drought occur after sowing, the seed will be destroyed, or if rainfall be excessive it may rot. In both cases the crop must be resown. From 20 to 25 inches of rain are enough provided it falls at timely intervals. Under favourable conditions the young plant will put forth four or five leaves in a fortnight, and weeding then becomes necessary. Between the rows, this is done by the bullock hoe, but on the rows, the weeds are removed by hand. Bullock hoeing is carried on at intervals of a fortnight till the pods appear.

Picking.

Crop.—The bolls ripen and open in October, and the cotton is then ready for picking. The first generally takes place at the end of October or beginning of November. If the crop is a good one, three to seven pickings can be made, according to the kind of cotton grown. The total cost of cultivation has been estimated at about Rs. 13 to Rs. 15 per acre.

Cost.

Seasons.

In the Central Provinces the method of cultivation does not differ materially from that in Berar. The soil is prepared for sowing in May to June; the seed is sown in June; picking commences in November to December, and is completed from February to March.

[*Cf. Medlicott, Cotton Handbook for Bengal, 1862, 254-84; Cassels, l.c. 194-227; Ann. Rept. Ind. Mus. (Indust. Sec.), 1894-5, 23-4; Fuller, Note on Outturn of Land under Principal Crops, Cent. Prov., 1894, 26-30; Middleton, l.c., Cottons of Cent. Prov. Berar and Khandesh, 12-3; F. W. Francis, Cot. Cult. in Berar. (ser. H.A.D.), 1898, No. 2; R. S. Joshi, Exper. Cult. of Egypt. Journ Ind., April 1907, ii., pt. ii., 171-92.]*

Having devoted so much space to the chief cotton-producing areas of India, an effort may now be made to abbreviate as far as possible the accounts that follow of the other provinces to the particulars of chief importance :—

D. P.,
iv., 13 -
Nizam's
Dominions

NIZAM'S DOMINIONS.—Area and Production.—The authoritative figures for 1903-4, show the area to have been 2,660,713 acres and the yield 982,867 cwt., or 275,203 bales. The largest cotton area is the Aurangabad Division, which in 1903-4 grew 1,464,116 acres. Then follow Gulbarga, 874,032 acres; Bidar, 232,096 acres; and Warangal, 75,161 acres. The forecast for 1905-6 reported an area of 2,537,000 acres and a yield of 206,000 bales, or 735,714 cwt.

The trade returns for 1905-6 show that the net export was 801,144 cwt., or 65,430 cwt. in excess of the estimated outturn. The exports went chiefly to the town and Presidency of Bombay, and a considerable quantity to the Madras ports.

D. P.,
iv., 96- .
Rajputana
and Central
India.

3. RAJPUTANA AND CENTRAL INDIA.—Area and Production.—The area for 1904-5 was 469,000 acres in Rajputana and 846,000 acres in Central India, a total of 1,315,000 acres. The yield for the same year was 1,150,000 cwt., or 322,000 bales. The estimated area and yield for the following year were 289,000 acres and 61,000 bales in Rajputana; 968,000 acres and 129,000 bales in Central India. The latest statistics (1906-7) estimate an area of 428,000 acres in Rajputana; 1,117,000 acres in Central India; with a yield in bales of 176,000 in Rajputana; 291,000 in Central India, giving totals of 1,545,000 acres and 467,000 bales.

The net export trade of Rajputana and Central India amounted in 1905-6 to 856,934 cwt., and as the estimated outturn in that year was 190,000 bales, or 678,571 cwt., the exports for the year were considerably in excess of the outturn. The largest share of the exports go to the town of Bombay, the United Provinces and the Presidency of Bombay. The Central Provinces, the Panjáb, and the towns of Calcutta and Karachi also receive

considerable quantities. The imports come chiefly from Bengal, the United Provinces, the Central Provinces and Berar.

AGRICULTURAL OPERATIONS.—Rotation.—The soils are fertile though light. They fall under Middleton's third class, which yields the Bengals of commerce. The plant is grown as a mixed crop, usually with *tīl*, *arhar* (*Cajanus indicus*) and *san* (*Crotalaria juncea*), etc. The ground is prepared by ploughing and manuring. The seed is then sown broadcast in the month of April or June, and the land immediately after is lightly ploughed and later on again ploughed. Picking commences in October and is completed by the end of the year. The cost of cultivation has been estimated at Rs. 25 per acre. [*Cf.* J. Forbes Royle, *l.c.* 309-29; Medicott, *l.c.* 1862, 243-53; Middleton, *Rajputana Cotton*, *l.c.* 16.]

Manures.
Sowings.
Seasons.
Cost.

4. **MADRAS.**—Watt, *l.c.* 128-31, 151.—**Area and Production.**—Madras ordinarily grows about 14 per cent. of the cotton crop of British India, or 9.2 per cent. of the entire cotton area. In 1904-5 the total was 2,007,297 acres. The principal districts are usually the following (the figures denoting the acreages in 1904-5):—Bellary, 408,388; Karnul, 268,067; Tinnevely, 250,521; Coimbatore, 256,948; Guntur, 210,487; Anantapur, 171,051; Cuddapah, 127,854. The yield for the same year was 132,000 bales, or 471,428 cwt. The estimated area and yield for the following year were 1,634,000 acres and 148,000 bales (528,571 cwt.). The latest available figures for the year ending December 1906 show an estimated area (*raiyaṭwari*) of 1,544,000 acres, with a yield for the same period of 151,000 bales.

D.E.P.,
iv., 99-108.
Madras.

Traffic.—The most noteworthy point regarding the trade of Madras in 1905-6 is the fact that the exports from the Presidency exceeded the outturn. The net export was 864,947 cwt., or 336,376 cwt. in excess of the outturn, which was drawn from beyond the Presidency. The Madras ports had a net import by rail of 932,336 cwt., and by sea coastwise of 10,195 cwt., thus giving a total import of 942,531 cwt. The foreign exports came to 800,479 cwt., and this left 142,052 cwt. as the supply of the Madras town mills.

AGRICULTURAL OPERATIONS.—Forms of Plant.—There are two forms of indigenous cotton usually grown in Madras, one depending on the south-west monsoon, the other on the north-east. The former is sown between May and July, the latter, between September and November. In Tinnevely both are sown in the same season, October to November. In the Tamil districts these crops are known as *uppam* and *nadam*. The *uppam* crop is generally sown on black cotton soil, the *nadam* on red or gravelly soils. These produce the four commercial forms known as Tinnevellys, Westerns, Coconadas and Salems. Manure is seldom added, but cowdung or wood-ashes may sometimes be lightly scattered over the ground; and if cattle are not permitted to browse on the fields, the leaves and twigs of the previous year often remain, and thus very possibly carry disease from one crop to another. Irrigation is seldom resorted to, and the *raiyaṭ* has to depend for the successful growth of his crops on the periodical rains.

Two Crops.

Seasons.

Manure.

Irrigation.

Associated Crops.

Rotation.—In exceptional cases cotton is grown continuously, but the general practice is to have a rotation. The principal rotation crops are *kambū* (*Pennisetum typhoides*) and *varigu* (*Panicum mitaceum*), sometimes also *cholam* (*Sorghum vulgare*) and horse or Bengal gram. If the land is clean, three ploughings before sowing are ordinarily sufficient, but more may be necessary. The soil is ploughed in a drier condition than for grain crops.

Ploughing.

Seed.—The seed, which has to be prepared as in other provinces, is generally sown broadcast, and as a rule the same stock is sown over and over again. The seed rate is about 10 lb. per acre. In some districts, however, it is drill-sown in parallel lines, alternately with pulse. The seedlings appear between the third and seventh day. When they are three weeks old the plantation is hand-weeded, and the process repeated several times during growth. The plants begin to flower about the fourth and to ripen their fruit about the sixth month of their growth. In some cases this does not take place till the eighth month. In Tinnevely, however, the first blooms appear in the third month after sowing and the first bolls open in the fourth month.

Weeding.

Seasons.

Crop.—The pods, as a rule, are not collected as they ripen, but are allowed

Insect Pests.
Cost.

to remain until the whole crop of the field is ready. The time of harvesting varies, according to the district and time of sowing, from January to August. The cotton crop in Madras seems to be specially liable to the attacks of numerous insects and fungal parasites. An ordinary crop of cotton (in form of seed-cotton) in Tinnevely runs from 750 to 900 lb. per acre, while 500 lb. is stated to be a fair average when all sorts of soil are taken into consideration. The cost of cultivation varies considerably in different districts. In Anantapur it has been estimated at Rs. 2-13-2 per acre; in South Canara at Rs. 14 per acre. [Cf. Buchanan-Hamilton, *Journ. through Mysore, etc.*, 1807, ii., 157-8, 221-3, 254, 313-4, 326-7, 450-1, 545; Royle, *l.c.* 464-537; Cassels, *l.c.* 262-3; J. Talboys Wheeler, *Handbook on Cotton Cult. in Madras Pres.*, 1862; Gribble, *Man. of Cuddapah Dist.*, 1875, 201-4; Nicholson, *Man. of Coimbatore*, 1887, 232-5; *Cotton in Madras Pres.*, *Agri. Dept. Mad.*, *Bull.* 1890, No. 9; S. Iyer, *Rept. on Growth of Cotton in Tinnevely*, *Agri. Dept. Mad.*, *Bull.* 1891, No. 19; Middleton, *l.c.* 7-9; *Rept. on Operations Agri. Dept. Mad.*, 1903-4, 5; *Madras Weekly Mail*, Sept. 8, 1904, 248; Nov. 24, 1904; *Proc. Agri.-Hort. Soc. Mad.*, April-June 1905, 28-31, 36-7.]

D.E.P.,
iv., 147-
ysore.

MYSORE AND COORG.—Area and Production.—The area under cotton in 1904-5 was 71,000 acres and the yield 17,857 cwt., or 5,000 bales; in 1905-6, 76,000 acres with the same yield. The principal districts are Chitaldrug, Tumkur, Mysore and Shimoga. The final estimate for 1906-7 shows a total of 89,000 acres and a yield of 10,000 bales. In 1905-6 Mysore had a net export of 40,287 cwt., or 22,430 cwt. in excess of the estimated outturn. Almost all went to Bombay Province, while small quantities found their way to the Province of Madras, the Madras ports and the town of Bombay. The imports came from the Provinces of Bombay, Madras, and the town of Bombay.

Pruning Cotton.

Cotton is not an important crop, and there is little of an exceptional character to be recorded regarding either the plant grown or the methods of cultivation pursued, except that after giving a crop the plants are cut down close to the ground, and in a month after the succeeding rainy season they produce a second crop about twice as large as the first. This appears to be one of the few records in modern times of the pruning of cotton. Hove records, however, that in Gujarat the red-flowered plant was regularly pruned during his time (1787). The older writers on cotton frequently allude to the practice prevailing in the West Indies. [Cf. Watt, *l.c.* 94, 259, 286, 309, 322.] It is curious that it should have survived in Mysore, a country closely connected with one of the once famed red-flowered cottons. [Cf. Buchanan-Hamilton, *l.c.* 1807, i., 40, 203, 378-9, 411; iii., 323-4, 351; Lewis Rice, *Mysore Gaz.*, 1897, i., 125-6.]

D. P.,
iv., 117-2
Panjáb.

5. PANJÁB.—Area and Production.—On an average of the five years ending 1904-5 the area under cotton in the Panjáb represented about 7.3 per cent. of the total area under cotton in British India. For 1903-4 the Panjáb area, including the North-West Frontier and Native States, was 1,747,000 acres and the yield 1,492,857 cwt., or 418,000 bales. The estimated area for the following year (1905-6) was 2,017,000 acres and the yield 205,000 bales, or 732,142 cwt. The final forecast for 1906-7 gives the area as 1,408,000 acres in the Panjáb and 61,000 acres in the North-West Frontier, a total of 1,469,000 acres and yield of 370,000 bales. The most extensive areas returned for 1904-5 were:—Lyallpur, 165,849, acres; Lahore, 142,621; Hissar, 96,862; Rohtak, 95,880; Gurgaon 92,859; Karnál, 75,008; Multan, 70,342; Gujranwála, 53,488; Sháhpur, 31,155; and Montgomery, 37,474. In the North-West Frontier, Peshawar, 19,658 acres.

Area and
Production in
1906-7.

Traffic.—The net exports from the Panjáb in 1905-6 amounted to

SIND SUPPLY

568,307 cwt. As the outturn in the same year was 732,142 cwt., it thus exceeded the net export by 163,835 cwt. The largest quantity goes to the port town of Karachi, while considerable quantities also are consigned to the towns of Bombay and Calcutta. The imports come chiefly from the United Provinces. Delhi is the most important manufacturing centre in the province.

Soils, Manures, etc.—The soil of the Panjáb is generally well suited to the cultivation of cotton, if irrigated or subject to inundation. All kinds of productive soils appear equally well adapted. Manure is frequently applied, and irrigation either by canals or wells is the general rule. In some of the eastern districts cotton is raised as an unirrigated crop, but nearly always in positions where the young plants can, if necessary, be watered from a neighbouring tank. The crop is generally mixed with others, of which the commonest are *til*, melons and pulses. Throughout the eastern districts it is the usual practice to sow *Hibiscus cannabinus* in strips along the edge of the cotton fields, or in alternate rows with the crop. In the Central Panjáb certain leguminous crops (species of *Melilotus*, *Trigonella*, etc.) are commonly sown with the cotton, as an after crop to be used as fodder for well-bullocks.

Seasons, Crop, etc.—The period of sowing varies in different parts of the province and is largely influenced by the rainfall and the race of plant grown, as also the altitude of locality. In Gurgaon from March to May it is sown near wells, or where there are other means of irrigation, and in June to July on rain lands as soon as the first showers break. In Shahpur and other districts sowings generally go on from the middle of February to the end of March, and in well-watered lands to April or May. The seed is sown broadcast at about the rate of 8 to 12 seers to the acre. The crop requires to be weeded and watered several times during growth. Picking takes place about November and December. The pods do not all ripen at once, and it is necessary to go over the field several times. Picking ought to be completed before January owing to the danger of loss from frost. It is difficult to give a precise statement as to the cost of cultivation. It differs considerably in some districts, and largely depends on the method of irrigation and the use or not of manure. On land both irrigated and manured, the highest figures quoted are in Jalandhar, Rs. 37–13–4 per acre; the lowest in Jhang, Rs. 10–0–9 per acre. [*Cf.* Royle, *l.c.* 301–9; Medlicott, *l.c.* 218–28, 233–42; Stewart, *Pb. Pl.*, 1869, 22; *Dist. Gaz. Pb.*, 1890–1902; *Settl. Rept. Jalandhar*, 1892, 123–4; Middleton, *l.c.* 14–5.]

Kash ir.—Lawrence (*Valley of Kashmir*, 1895, 340–1) gives the following account of cotton. It is found all over Kashmir up to certain elevations. Never less than three ploughings are given before sowing, and the clods are also pulverised by mallets. The seeds are soaked in water and mixed with ashes, but beyond this the plant receives no manure. Sowing takes place at the end of April and in May, and about 48 seers of seed are sown to the acre. It is cultivated only for home consumption. The outturn is generally stated to be about two maunds (164 lb.) per acre.

6. UNITED PROVINCES.—Area and Production.—On an average of the five years ending 1904–5, the cotton crop in these Provinces represents about 6·6 per cent. of the total cotton area in British India. In 1904–5 the area, including Native States within provincial boundaries, was 1,201,000 acres. In Agra, the districts of Aligarh, 152,407 acres; Muttra, 146,981; Agra, 118,591; Bulandshahr, 109,570; Meerut, 76,866; Etáwáh, 61,090; Hamérpur, 52,629; Cawnpore, 52,363; and Bánda, 43,591. In Oudh, the districts of Hardoi, 11,816; Unao, 10,776; and Lucknow, 2,579. The yield for the same year was 1,314,285 cwt., or 368,000 bales. For 1905–6 the total area for the Provinces was 1,372,000 acres and the outturn 394,000 bales, or 1,407,142 cwt., while the final estimate for 1906–7 gives an area of 1,489,000 acres and a yield of 638,000 bales. (*Agri. Journ. Ind.*, 1906, i., pt. i., 37-43) on the conditions determining the area sown with cotton in the United Provinces should be consulted.

Traffic.—The net export trade of the United Provinces amounted in 1905-6 to 1,497,159 cwt., or 90,012 cwt. in excess of the outturn. The exports went chiefly to the ports of Bombay and Calcutta and to the Panjáb, small quantities also going to Bengal, Rajputana and Central India. The imports largely came from the Panjáb, Rajputana and Central India, while smaller quantities also came from the Central Provinces, Berar and the port of Bombay. The chief manufacturing centre is Cawnpore.

Soils, Rotation, etc.—The best grade of cotton soils in the Provinces are rich loams, which are either directly manured or reap some benefit from manure applied to a previous crop. Cotton is also grown on poor soils such as the calcareous tracts in the neighbourhood of the great rivers. At present cotton appears to have no definite place in the systems of cropping in vogue, which is said to be partly due to the uncertain distribution of rainfall and the consequent uncertain nature of the crop, partly to the low yield and the narrow margin of profit usually secured. Subbiah (*Cult. of Longer-stapled Cottons at Cawnpore Exper. Station*, 1901, 28) suggests various rotations which those interested should consult. On the better classes of soil the crop is generally grown alone, except where rows of *arhar* are sown at intervals of 5 to 7 yards, but on poor ground it is almost invariably associated with four or five subordinate crops, of which *arhar* and *til* are the chief. Subbiah recommends particularly in the cultivation of longer-stapled cottons on irrigable lands, a mixture of cotton and maize in alternate rows at a distance of $1\frac{1}{2}$ to 2 feet. The seed is sown broadcast generally about the middle of June and then ploughed in. The seed rate is about 4 to 6 seers per acre. Irrigation is applied only to about one field in seven. Picking commences about the beginning of October and is in progress from then till the end of January if not cut short by frost. If the plants are allowed to remain after January and are watered and hoed two or three times, a second gathering even better in quantity and quality may be obtained in May and June. On the richer classes of irrigated land Subbiah gives 140 to 230 lb. of clean fibre as an average outturn per acre for the rainy-weather crop, and about as much for the hot-weather crop, giving a total of 280 to 460 lb. of fibre. The cost of cultivation per acre as estimated by Duthie and Fuller amounts to Rs. 22-9, but by Subbiah at the Cawnpore Station from Rs. 61 to Rs. 73.

Exotic Cottons.—Subbiah's report deals mainly with the efforts made at the Cawnpore Experimental Farm to grow long-stapled American and Egyptian cottons. As a rule the American cottons did better than the Egyptian, since it was found the growing season was too short to allow the latter coming to maturity. It is, therefore, laid down that in introducing long-stapled cottons, it is essential that those be chosen which mature in their native habitat in about the same time that the local country cotton does. [*Cf. Royle, Cult. and Comm. Cotton in Ind.*, 1851, 262-301; *Medlicott, L.c.* 165-218, 229-32; *Exper. Farm Repts. Cawnpore*, 1890-1904; *Middleton, L.c. Cottons of United Prov.*, 15-6; Subbiah, *Cotton Acclim. at Cawnpore*, in *Pioneer Mail*, March 17, 1899, 27; *Rept. Govt. Bot. Gard. Saharanpur*, 1904, 3-4.]

7. BENGAL.—Area and Production.—In the province of Bengal as now understood, the area under cotton represents only about 0.6 per cent. of the total area in India. In 1904-5 the estimated area and yield were 78,000 acres and 20,000 bales (71,428 cwt.); in 1905-6, 73,000 acres and 17,000 bales (60,714 cwt.); while the most recent estimate for 1906-7 forecasts the area at 76,477 acres (39,947 acres early cotton and 35,530 late) and the yield 16,030 bales (6,250 early and 9,780 late), or 57,250 cwt. The districts with largest areas are:—Saran, 14,400 acres; Sambalpur, 11,693; Santal Parganas, 10,700; Singhbhum, 7,000; Manbhum, 5,100; Darbhanga, 3,792; Cuttack, 3,400; Muzaffarpur, 3,000, etc.

Traffic.—The trade returns for 1905-6 show that the Province of Bengal, exclusive of Calcutta, made a net import of 86,224 cwt. The

CULTIVATION
Bengal**

outturn for the same year was 60,714 cwt., so the total amount available for local purposes was 146,938 cwt. The town of Calcutta imported by rail and river and by sea (coastwise) 1,063,601 cwt. and exported 90,596, giving a net import of 973,005. By adding the foreign imports (2,331 cwt.) we get a total net import of 975,336 cwt. The foreign exports for the same year were 498,567 cwt., so that the amount available for the Calcutta mills was 474,769 cwt. Including the supply for the province (146,938 cwt.), a total of 645,505 cwt. met the local consumption.

Local
Consumption.

Crops, Seasons, etc.—There are generally speaking two cotton crops in Bengal, the early, sown during the monsoon rains and harvested during the cold weather, and the late, sown at the close of the rainy season and harvested during the hot weather. Early cotton is grown chiefly in the Santal Parganas, Sambalpur, Manbhum, Singhbhum and Angul; late cotton in Saran, Muzaffarpur and Darbhanga.

Two Crops.

It is not deemed necessary to detail the methods of cultivation or other such particulars, since the crop is hardly of sufficient value. In Saran (the largest cotton-growing district of Bengal) cotton is sown as a secondary crop, the seed being sown broadcasted. The so-called *bhadoi* cotton of Saran is sown in January and February and reaped in August; the *bysakhi* sown in June and July and harvested in April. Maxwell-Lefroy (*Notes on Cotton in Bihar, Bull. Agri. Res. Instit., Pusa, Feb. 1904*) mentions three ways by which cotton cultivation might be improved—by drainage, growing with other crops, and sowing at another time of year. He considers the failure of cotton in Bihar as due largely to its inability to withstand the wet season, and the improvements he suggests have as their main object the lessening of the effects of the wet weather. He advises sowing in August to October instead of June as the young plants would not then have to struggle through the long rainy season, and the insect pests, which are worst in June, July and August, would not affect the crop seriously. In a note drawn up at the request of the Lieutenant-Governor of Bengal, Mollison (*Ind. Pl. Gaz., March 12, 1904, 345*) gives an account of recent experiments in Bihar, which the reader should consult; also the efforts made by Messrs. Shaw, Wallace & Co. of Calcutta to grow tree cottons in various parts of the province. Particulars of these latter experiments have been given by Sly (*Proc. Govt. Ind. Dept. Rev. and Agri., March 1905.*) [*Cf. Royle, Cult. and Comm. of Cotton in India, 1851, 241-62; Grant, Rural Life in Bengal, 1860, 187-8; Hunter, Stat. Acc. Beng., 1877, xvi., 105, 342-3; Sen, Rept. Tree Cotton.

8. EASTERN BENGAL AND ASSAM.—*Area and Production.*—The area under cotton represents some 0·3 per cent. of the total under cotton in British India. In 1904-5 it was estimated at 50,000 acres and the yield 17,000 bales (60,714 cwt.); in 1905-6 at 61,000 acres with the same yield; while the latest forecast, namely for 1906-7, puts the area at 57,333 acres and the yield at 13,680 bales (48,857 cwt.). The Chittagong hill tracts are there shown to have an area of 26,636 acres; Garo hills, 23,000; Nowgong, 3,400; Sylhet, 2,060; Khasia and Jaintia hills, 1,000; while smaller areas are recorded in Cachar, Sibsagar, Goalpara, Jalpaiguri and Kamrup.

9. BURMA.—*Area and Production.*—Burma produces about 0·9 per cent. of the total cotton crop of British India. The area for 1904-5 was estimated at 189,000 acres and the yield 139,285 cwt., or 39,000 bales.

D. P.,
iv., 148-
ur a.

Area and
Production in
1906-7.

The relative importance of the chief localities in Upper Burma may be expressed by the returns of the year named :—Myingyan, 65,511 acres ; Sagaing, 49,575 ; Meiktila, 36,161 ; Lower Chindwin, 13,672 ; and in Lower Burma, Thayetmyo (Lower Burma portion), 12,275. In the following year (1905-6) the estimated area and outturn were 183,000 acres and the yield 35,000 bales (125,000 cwt.) ; while for 1906-7 the estimates were 186,000 acres, with the same yield.

Traffic.—The trade returns for 1905-6 show that Burma had a net export of 39,225 cwt. The outturn for the same year was 125,000 cwt., so the net supply available for local consumption was 85,775 cwt. Almost all the exports went to Calcutta, but small quantities were also sent to Bombay port and to Pondicherry.

Soils.

Crops, Seasons, etc.—The most suitable areas for cotton are found in the dry zone of Upper Burma. It is there cultivated on good and medium black cotton soil but is also found on inferior soils of a lighter colour. Burkill (in a *Report on Cotton in Burma* dated March 25, 1904) states that cotton is grown on *kain* land (land periodically flooded by rivers), on *taung yas* (forest clearings), and on *ya* (high, dry land). On *kain* land the seed is sown in September after the floods have left the ground, but such cultivation is now rare. On forest clearings cotton is also said to be unimportant, as the land is more serviceable for other crops. The most important, therefore, is the third, viz. cotton grown on high, dry land.

Races of Plant.

Two kinds of cotton are in general cultivation, the annual (*wa-gale*), which is sown in April and May and yields from October to December, and a perennial, (*wa-gyi*) which is sown at the same season as the annual but continues on the fields for three years and yields annually in February or March. The annual is most extensively grown. *Wa-gyi* is a common crop in Minbu and Thayetmyo, but rare elsewhere. Manuring is general, farmyard manure being considered best. The yield per acre of seed-cotton Burkill gives as follows :—on first-class soil, 73 viss (viss = 3·65 lb.) ; second-class soil, 42 viss ; third-class soil, 32 viss. In 1901-2 the average yield per acre of clean cotton for the whole province was only 80 lb. ; according to the figures discussed in the *Dictionary* (taken from reports by the Deputy Commissioner of Meiktila), the yield would appear to average from 125 to 250 viss an acre of seed-cotton. [*Cf. Browne, Stat. and Hist. Acc. Thayetmyo*, 1873, 87-8 ; *Rept. on Settl. Oper. Meiktila Dist.*, 1896-8, 7-8 ; *Arnold, Monog. on Cotton Fabrics and Cotton Indust. IV. SOILS AND MANURES.—As already mentioned, Middleton (*Agri. Ledg.*, 1895, No. 8, 117) classifies the Indian cotton soils into three well-marked sections :—(1) rich black clay soils, such as those of Surat and Broach, which produce the finest cottons ; (2) soils like those of Kathiawar, Khandesh, Berar and the Central Provinces, that produce the second-grade cottons ; and (3) a very large area, too sandy or with too small a rainfall to ripen the finer cottons—the source of the Bengals of commerce. Bombay Presidency has soils and climates of all three grades, but it is much more favourably placed than other provinces, by having a larger proportion of both the first and second grade soils.

Indo-Gangetic
Alluvium.

In his paper on Indian soils, Leather (*Agri. Ledg.*, 1898, No. 2) makes four main heads :—the Indo-Gangetic alluvium ; black cotton or *regur* ; red soils lying on metamorphic formations (in Madras) ; and laterite soils. The first consists generally of a yellow-coloured alluvium, sometimes sandy, sometimes stiff clay. The only rocky particles larger than sand which this expanse of land contains is the nodular limestone, *kankar*. (For theory of formation, see p. 711.) Leather

states that in the samples he examined, the amount of phosphoric acid, though small, was more than in other Indian soils. The commonest form of red soil is a sandy clay coloured by iron peroxide. It may be derived from the rocks *in situ* or from the same products of decomposition washed by rain to lower levels. Laterite soils are simply soils lying on or adjacent to laterite rocks. The composition of both these classes, according to Leather's analyses, varies considerably, but, like other soils of India, both are deficient in phosphoric acid and nitrogen.

It is on the black cotton or *regur* soils that Indian cottons are generally grown. Typical *regur* areas are well represented in the Bombay and Madras Presidencies. The condition indicated may be described as a highly argillaceous, calcareous clay, very adhesive when wet, and from its absorbent nature expanding and again contracting to a remarkable extent. In consequence, during the hot weather, such soils become fissured in every direction by huge cracks, which in depth vary greatly. In some parts, for example at Akola, they have been reported as seen from 40 to 60 feet deep. Underlying the *regur* is a bed of yellow-white earth consisting of clay, lime and sand intimately mixed. It has generally been supposed that the black colour is due to an admixture of organic matter, but Leather is of opinion that this cannot be the case, but that it must be due to the presence of some mineral substance. He also holds that these soils are not inordinately fertile. In the matter of phosphoric acid and nitrogen they are very poor. The fact that they do produce crops liberally, he thinks, is due to their power of retaining moisture and to their contraction, which not only forms deep and wide fissures, but causes the surface to crumble to a powder, which, getting carried into the larger fissures, thus brings about a continual inversion of the soil.

As regards the manuring of cotton crops, it has been proved by experiment that cotton responds promptly and profitably to a judicious fertilisation. The following account is taken from the results of the experiments carried out by the United States Department of Agriculture. It may be stated in the first place that a complete fertiliser is needed for cotton, *i.e.* one containing soluble phosphoric acid, potash and nitrogen. Neither phosphoric acid nor potash give as good results separately as when combined. The most effective constituent is phosphoric acid, but nitrogen alone has little or no effect. The best form of nitrogenous manure appears to be cotton-seed meal and nitrate of soda. The proportions of the three constituents in a complete fertiliser should accordingly be approximately, nitrogen 1 part; potash 1 part; phosphoric acid $3\frac{1}{2}$ parts. The quantity used per acre varies widely with the nature and condition of the soil, but the maximum should be an amount yielding nitrogen 20 lb; potash 20 lb.; phosphoric acid 70 lb. The profit from manuring cotton is much increased by antecedent proper preparation of the soil. Farmyard and similar bulky manures are said to be more efficient as soil-renovators than as specific fertilisers for cotton. The concentrated fertiliser should be applied in the drill, not broadcasted, at a depth of not more than 3 inches, and well mixed with the soil.

Diseases.

V. DISEASES AND PESTS.—While many writers make mention of a “deterioration” of the cotton plant as having taken place in India, remarkably little has been said of the actual diseases of the crop. Compared with tea or coffee, Indian cotton can hardly be said to be affected with disease further than failure of crops through unfavourable seasons. Maxwell-Lefroy, Entomologist to the Government of India, has, however, recently issued some useful and suggestive *Notes on Cotton in Bihar* (*Bull. Agri. Res. Inst. Pusa*, Feb. 1904) in which he gives brief accounts of some 14 pests met with in the cotton of that province, of which 3 are at present known in Bihar only and 11 are general to the cotton tracts of India. He groups these pests under four sections as follows:—

Chief Pests.

(a) *Insects attacking the leaves and seen chiefly up to September.*—Under this series he places the following:—(1) hairy caterpillar; (2) cotton-leaf caterpillar; (3) the cotton bud-worm; (4) spotted boll-worm; (5) the white weevil; and (6) the cotton leaf-hopper. (b) *Insects in the stem:* (7) the stem-borer and (8) the stem-weevil. (c) *Insects in the boll:* (9) the spotted boll-worm and (10) the pink boll-worm; (11) the red cotton-bug; and (12) the dusky cotton-bug. (d) *Miscellaneous:* (13) the mealy bug; and (14) the large blister beetle.

Boll-worms.

He then concludes with a recommendation to destroy systematically all traces of the pests as they appear. In August and September a careful outlook should be kept for boll-worms, and all shoots or bolls showing signs of these should be destroyed. More recently Maxwell-Lefroy has issued a paper entitled *The Insect Pests of Cotton in India* (*Agri. Journ. Ind.*, 1906, i., pt. i., 49-61; also *Memoirs Dept. Agri. Ind.*, 1907, i., No. 2). This will be found to furnish fuller details of six of the more important of the pests, while a further note (*The Pests of Introduced Cottons*, 1907, ii., pt. iii., 283-5) furnishes a few particulars regarding the pests to which exotic cottons are liable.

Exotic Cottons.

The Cotton Mite.

A curious disease often present to a large extent in India is known to the Natives as *gosai* or *tulsi* (the *Ocimum*-like). The former name (“the ascetic”) denotes the non-flowering and fruiting of badly affected plants, and the latter their colour and general appearance seen at a distance. The leaves, at first large and exceptionally vigorous, ultimately curl up and become small, very numerous, and are then seen to be coated with a woolly formation known as *Erinosis*—a growth at first supposed to be of fungal origin but now definitely ascertained to be caused by a mite (*Phytoptus gossypi*). This perplexing pest is often very prevalent in Gujarat, as much as 5 to 10 per cent. of the bushes being thereby rendered more or less non-productive. It might be dealt with similarly to the treatment of *Erinosis* on the vine or other plants, namely by sulphur or kerosene emulsion. [Cf. G. F. Atkinson, *Diseases*, and L. O. Howard, *Pests*, in Dabney, *The Cotton Plant*, 1896, 279-350.]

Weevil-resist
Adaptations.

esistant.—O. F. Cook has written a highly interesting and most suggestive report on *Weevil-resisting Adaptations of the Cotton Plant* (*U.S. Dept. Agri. Bull.*, 1906, No. 88). The form specially investigated is the *kekchi* cotton of Guatemala. This he describes as a dwarf annual short-season variety with numerous features which, in the absence of sufficient numbers of *keleps* (the so-called Guatemalan ant that kills the weevil), affords material assistance in protecting the crop against the ravages of that pest.

The plant in question matures very early and is more productive than might be expected. He classifies the protective developments into the following :—(1) those calculated to avoid the weevils by general habits of growth ; (2) those which exclude the weevils or at least hinder their operations in the buds and bolls ; (3) those which attract insect enemies such as the weevil-eating *kelep* ; and (4) those which prevent the development of the weevil larvæ even after the eggs have been laid.

[*Cf. Publications of U.S. Dept. Agri.* :—Riley, *Cotton-worm and Boll-worm* (*Entomol.*), 1885, 1-381 ; and Bibliography, 382-4 (numerous plates) ; Malley, *Boll-worm of Cotton*, (*Entomol.*) *Bull.* 1891, No. 24 ; Howard, *Insects that Affect Cotton Pl.* (*Entomol.*), 1897, No. 47 ; Smith, *Wilt Disease of Cotton*, (*Veg. VI. CLEANING, GINNING AND BALING, ETC.—The scientific officers who accompanied Alexander the Great and his successors to India described the cleaning, ginning, spinning and weaving of cotton in such detail that it is matter of great surprise that these operations took so much time and study to be fully accepted in Europe. There may be said to have been known in India from time immemorial two forms of gins, viz. the foot roller and the *churka*. The former is very little used nowadays, though specially applicable to some of the forms of hard-seeded cotton. The latter consists of two rollers of wood, or of iron made to revolve towards each other by hand labour, communicated by a crank or wheel. The seed-cotton is presented at one side against the rollers, the lint passes through, and the seed falls down in front. This is improved by modern contrivances and worked by water power or steam.

The word "gin" is an abbreviation of "engine" which began to have the meaning of machinery shortly after the discovery of steam. The use of that name in India usually denotes the employment of foreign machines for separating lint from seed. A special gin was, for example, invented by Whitney to remove the firmly adhering wool of *G. hirsutum*, and came to be known as the "saw-gin" because it consists of a series of blunt toothed circular saws made to revolve within the interstices of an iron bed which forms the base of a large hopper. The fibre is caught by the teeth and dragged through, leaving the seed behind. This was, however, found to injure the cotton and, moreover, was not necessary with the Sea Island and other cottons, where the lint separates readily. This led to Macarthy's gin, now very extensively employed for long-stapled cottons. In this contrivance the seed-cotton is drawn in by a leather roller between a metal plate, known as the "doctor," which is fixed tangentially to the roller. A blade called the "beater" is so adjusted as to strike the cotton repeatedly and thus cause the seed to fall out.

It may be said, however, that no modern machine injures the lint and seed less than the Native *churka*—its one defect is its slowness, and therefore inaptitude for dealing with large quantities. To this fact is due a modern feature, and one of no small importance to the Indian

cotton trade, namely the establishment all over the country of large public ginning and pressing mills, each situate in a convenient position to drain the produce of a tract of country within which it often has a monopoly. Naturally this has not proved an unalloyed blessing, though it has had some beneficial results. The cultivators hardly anywhere nowadays gin their own cotton, but carry the produce of their fields to the steam ginning mills. It has already been pointed out that widely different lints are in consequence inseparably mixed and ginned together, and moreover the cultivators are given, or purchase, mixed seed. This, it is believed, has rapidly equalised and lowered the Indian staple, thus rendering it imperative for the Government to organise some system of seed culture by which the special evolutions of centuries of cotton-growing may not be irretrievably lost, before the cultivators have learned the value of special selection and intelligent interchange of seed.

In the official statistics published by the Government of India for 1906 there is said to have been in 1904, 951 cotton ginning, cleaning and pressing mills that gave employment to 85,559 persons. *Thacker's Directory* for 1905 enumerates 73 pressing and 47 ginning mills as those of chief interest. These figures show the extent to which the ginning and pressing of cotton have assumed importance.

The necessity for economy in freights was one of the chief arguments that gave birth to cotton presses. But that consideration would seem to have engaged attention from the very earliest records of raw cotton being exported from India. The Rev. Philips Anderson has shown that as early as 1684 special presses were sent out from England to Surat. For many years the pressing and baling of cotton were done almost exclusively in Bombay: nowadays the pressing is done at the ginning factories.

VII. COTTON-SEED: AN ARTICLE OF CATTLE FOOD AND SOURCE OF OIL.—One of the modern aspects of the Indian traffic in oil-seeds may be said to be the sudden development of a foreign demand for cotton-seed, mainly in the United Kingdom. In 1898-9 the exports were returned at 37,000 cwt.; in 1899-1900 at 43,000 cwt.; in 1900-1 they suddenly advanced to 225,000 cwt.; in 1901-2 they increased ten-fold, and became 2,036,000 cwt.; in 1902-3 they still advanced, viz. to 3,974,000 cwt.; in 1904-5 were 2,518,897 cwt.; in 1905-6, 3,891,339 cwt.; and in 1906-7, were 4,387,534 cwt. Thus, within five years, from being utterly insignificant the exports of cotton-seed sprang into the second place in quantity and the fourth in value of all the oil-seeds exported from India. This has very possibly been a consequence of the discovery of successful methods of hulling the seed, the decline of the American supply, or simply the extended use of cotton-seed oil as a material employed in the preparation of lard and margarine. But it is significant of India's consumption of oils and oil materials that even the very large exports of 1902-3 and subsequent years represent but from 10 to 20 per cent. of the amount available. Mollison (Inspector-General

of Agriculture) in a paper on cotton oil-seed (*Agri. Ledg.*, 1903, No. 9), pointed out that the seed of the United Provinces is best suited for the oil trade.

Oil.—After the cotton (lint) has been removed, the seeds are often subjected to a treatment calculated to remove any still adhering particles of floss. The cleaned seeds are then cut through and decorticated. It is particularly necessary that this should be done, since the cake after expression of the oil is used as an article of cattle food, for which it is generally believed it would be unfit were the hulls attached. The quantity of oil usually present averages from 20 to 25 per cent. of the weight of seed. But the process of manufacture varies according to the purpose for which the oil is destined. The decorticated seeds are subjected to cold pressure, when from 10 to 12 per cent. of oil is obtained. This is of a fine quality, almost devoid of taste, and is accordingly largely used in cookery, being specially valued for frying purposes. It is often sold in mixture with olive oil or is employed as an adulterant for the cheaper grades of that oil, or pure cotton-seed oil is sold under the name of olive oil. It is also extensively utilised in the production of lard. The cake obtained from this cold expressed seed is next subjected to a further pressure, by the hot process, when an extra supply of oil is obtained up to 10 per cent. By other methods from 15 to 20 per cent. of oil is at once expressed by the hot process, from decorticated or undecorticated seed, and the cake allowed to carry the balance. It is, in fact, generally believed that the presence of a fair percentage of oil is essential, otherwise the cake is useless for cattle food. But it should be here added that very little cotton-seed is in India pressed for oil, though valued as a fertiliser.

The sp. gr. of refined cotton-seed oil varies from 0.922 to 0.924, its iodine absorption is from 105 to 109, and its saponification equivalent ranges from 285 to 294. It has a slight tendency to dry, and congeals at 32° to 45° F. By freezing the oil the glyceryl salts, which are solid at low temperatures, are separated and constitute cotton-seed stearin, an important ingredient of margarine. No information can be discovered regarding the extent to which cotton-seed oil is prepared in India. A note by Burkill records his having inspected in Burma a ginning factory and oil mill owned by Jamal Brothers. The cake prepared is exported and the oil refined. The husk is used as fuel.

Cake.—From fairly ancient records regarding the Indian cotton trade, mention is made of the seeds as a useful by-product, employed to fatten cattle. It is said that they do not at first like the seed but soon take to it very kindly, and may be given a daily ration of as much as 6 lb. In the Nagpur Experimental Farm, 2 seers of cotton-seed are given daily to bullocks in place of oil-cake. Nevertheless in many parts of the country the seed is not valued even up to the present day; in fact in India as a whole, the seed can hardly be described as anywhere used by the Natives in the production of oil. The self-same cultivators who grow the cotton plant will raise special oil-yielding crops, the oil of which in some respects may be even inferior to that of the cotton-seed which they entirely neglect. This may proceed from the very generally accepted belief that cotton-seed cake is less wholesome than the whole seed. Mr. R. W. Bingham, who specially investigated the Indian oil-yielding plants half a century ago, said that cotton-seed was more used as an article of cattle food than as an oil-producing seed, and that the seed was considered a better food for working bullocks than even grain. He then added that he did not think it would pay to export the seed since owing to the fibre adhering to it, and perhaps other causes, it is very liable to heat and deteriorate in bulk. The fact that there is to-day a large and prosperous export trade in Indian cotton-seed shows the often unexpected turn that discovery or necessity gives to the trade commodities of the world. In fact, in the *Journal of the British Board of Agriculture*, Voelcker shows that recent results are distinctly in favour of Bombay undecorticated cotton cake, compared with Egyptian, especially when its lower price is borne in mind.

Various machines and processes for removing the fuzz from cotton-seed have been patented. Some burn off the velvet, others chemically destroy it, and still others mechanically brush it off. It is no doubt much desired to obtain an effectual and cheap removal of the fuzz, but meantime it is interesting to learn that undecorticated seed-cake finds a market. The chapter on Feeding Value of Cotton-seed by W. Kilgore (in Dabney, *The Cotton Plant*, 1896, 385-422) will be found to give full particulars on this subject. Other publications of interest are the summary of Dr. T. Thorpe's views (given in *Journ. Board Agri.*, 1898, 205-8).

Hulls and Waste Stems.—Recently it has been found that the hulls or entire seeds may be utilised in the manufacture of a superior grade of writing paper. The stubble, after the cattle have devoured all the edible portions of the plants left on the removal of the lint crop, may be decorticated and a useful fibre thus obtained. It is stated that 5 tons of stubble give a ton of bark, and that a ton of bark yields 1,500 lb. of clean fibre that can be even used as a jute substitute. [Cf. Cotton
Cell.

Formation.

VIII. THE COTTON FIBRE.—The cotton fibre is a unicellular hair arising from the fibril layer of the seed-coat. If taken from the seed of a ripe but unopened pod, it will be found to be a straight, flattened, hollow tube, not quite cylindrical but thickest a little below the middle, tapered abruptly below and more gradually to the apex. With growth, the cell wall thickens, becomes thinnest along the centre and thickest towards what may be called the margins. In consequence of this unequal thickening, maturity is marked by the thinnest parts shrinking most and thus causing the cell to become spirally twisted on itself. The cotton cell may hence be spoken of as a fibril from $\frac{1}{2}$ to 2 inches in length, twisted spirally. Wiesner (*Die Rohst. des Pflanzenr.*, 1903, ii., 240-1) gives a series of measurements to show that the broadest section generally falls a little below the middle. It is a noteworthy circumstance, and moreover one of practical importance, that the floss taken from a capsule always consists of fibres of various lengths. Allard (*U.S. Dept. Agri. Bureau Pl. Indust. Bull.*, 1907, No. 111, 13-5) has shown that this is frequently a consequence of certain cells separating from the seeds and uniting with other cells, thus producing the apparent though not real greater length. This discovery may prove of great value. Average Indian floss does not come to three-quarters of an inch in length, while some varieties of Sea Island have a staple two inches long. Evan Leigh (*The Science of Modern Cotton Spinning*) gives the following measurements as representative of the lengths (maximum) of cotton staples:—New Orleans, 1.16 inch; Sea Island, 1.80 inch; Brazilian, 1.31 inch; Egyptian, 1.52 inch; Indian (indigenous), 1.02 inch; Upland American grown in India, 1.21 inch; Sea Island grown in India, 1.65 inch. [Cf. Watt, *l.c.*, 1907, 25-51.]

Lengths of
Standard
Staples.

Cell-wall.

Structurally, the cotton fibre consists of a wall of almost pure cellulose, lined by a delicate layer of protoplasm, which disappears early in the growth of the fibre as the secondary placed deposits increase and a central core of endochrome is formed—the colouring material of the cell. The wall constitutes from one-third to two-thirds of the diameter of the cell. Recently an exceedingly interesting discovery was made by H. de Mosenenthal (*Journ. Soc. Chem. Indust.*, March 31, 1904), namely that the cotton cell-wall consists of two layers, termed the outer and inner, which are pierced by minute pores, leading into the lumen of the fibre. These

PROPERTIES OF THE FLOSS

pores, hitherto unobserved, offer an explanation of the way moisture penetrates to the interior. Among the ripe flosses of every grade is often present a certain percentage of quite unripe hairs. These are very thin, have weak cuticles, and show no twisting; they are the cause of much depreciation, since they cannot be worked up nor dyed in the same manner as fully formed flosses. In practical work such hairs are known as "dead cotton." According to Hanausek (*Tech. Mikroskopie*, 1900, 5-8; also Winton and Barber, transl., 1907, 58-68), *dead cotton* is commonest in coarser grades (Levantine and Indian) and rarest in Sea Island. [*Cf.* Flatters, *The Cotton Plant*, 1906, 59-92.]

Dead Cotton.

The commercial value of cotton is chiefly affected by the length and uniformity of the staple. Silkiness, fineness, strength, cleanness and colour are the other important factors. Tables showing the physical properties of the various staples of commerce are given by Hannan (*Text. Fibres Comm.*, 1902, 94-6), while Flatters contributes micro-photographs and comparative descriptions of the flosses of the following trade samples:—Florida, Brown Egyptian, New Orleans, Peruvian Rough and Hinganghat. As offered for sale, cotton always contains moisture varying from $7\frac{1}{2}$ to $12\frac{1}{2}$ per cent. over absolute dryness. With regard to the influence of moisture on spinning, the reader should consult Dobson (*Humidity in Cotton Spinning*, Sept. 17, 1894).

Commercial Properties.

When immersed in a solution of caustic soda, cotton fibre undergoes an important change. The cell-walls swell and acquire silky gloss. Cotton so treated is known as mercerised. The process was invented and patented in 1851 by John Mercer, a Lancashire calico-printer. The swelling of the fibre causes a shrinkage in length, it becomes more transparent, gains in strength and weight, while its capability for taking up certain dyes is vastly increased.

Mercerised.

Chemically, the mature fibre consists of almost pure cellulose with about 3 per cent. of other substances. The most important of these are cotton wax, fatty and pectic acid, endochromic colouring matter, and albuminous substances. The fibre is insoluble in water, alcohol, ether, fixed and volatile oils or vegetable acids, but soluble in strong alkaline solutions and is decomposed by concentrated mineral acids. Cuprammonia causes a complete disorganisation of the cellulose deposits.

IX. INDIAN MANUFACTURES.

The cotton manufactures of India may be said to be referable to three groups:—1. Indian Hand-loom goods. 2. Indian Power-loom goods. 3. Foreign Power-loom goods.

Hand-loom Weavers.

These three have to be clearly borne in mind both in connection with the present chapter and that on trade. The late Sir James Westland

said of India, and with some force, that "weaving is for the most part the pursuit of the bye-time of the persons who weave." That is doubtless the condition in many parts of the country to-day, but here and there centres of professional hand-loom weaving still exist where the village weaver holds an honoured position. He, in fact, turns out a fair portion of the dresses worn by the more conservative and orthodox members of the community. Increased prosperity of these hard-working and highly deserving craftsmen was entertained by some writers as likely to ensue when the repeal (in 1896) was announced of the tax on yarn, conjointly with the imposition of a countervailing duty on power-loom manufactures, both foreign and Indian. It was thought that all that need further be done, to restore and uphold the hand-loom industry, was to teach the Native weavers the use of the fly-shuttle and a few other such contrivances.

Fly-shuttle.

A century ago or more these very contrivances had in Europe been found quite useless in the contest with steam, but it was presumed conditions existed in India that raised the possibility of hand-loom improvement to a position of supreme importance. Hence it was urged, among other considerations, that "the hope of the hand-loom industry lies in the production of goods of a kind which cannot profitably be made by the power-loom, such as those compounded in an intricate fashion or made in a very complicated pattern. The fact that after a long struggle with the products of the mills, the hand-loom industry still survives, may be held to show that it has vitality to preserve it yet for many years." It would very possibly be nearer the truth to say that the hope of the hand-loom weaver lies in the restriction of his operations to lines that are too small to tempt the competition of the power-loom worker. It may, in fact, be safely affirmed that there is nothing either too fine in texture or too complicated in pattern for the power-loom manufacturer to produce. His advent on the field is alone restricted by the possibilities of profit. The finest Dacca muslins and the most intricate Kashmir shawls can be and have been produced by machinery cheaper than by hand labour. But there are markets eminently suited to the hand-weaver, such as the production of special *saris* and *lungis* of a particular shape and size that the power-loom producer does not successfully contest.

Hopeful
Markets.Special saris
or lungis.

There is this also in favour of the hand-loom weaver—he can purchase the very best English spun yarn and produce a quality of fabric admittedly superior to the very best power-loom textiles ordinarily turned out by the Indian mills. But, let it be repeated, his safety lies in the goods he manufactures being of a fancy or special nature, meeting local markets known to him, rather than in regular commercial articles intended for large markets.

Centres.

HAND-LOOM INDUSTRY.—It would occupy much time to review, however briefly, the chief centres of hand-loom production and the class of goods turned out. The figures given within brackets, in the enumeration that follows of the cotton-weaving centres of India, denote the number of *steam-power mills* in 1904. The square brackets show the provincial totals and the round brackets the district totals, while districts without figures have no power-loom mills.

Factories.

The districts most famed are:—PANJÁB [8]—namely, Dera Ismail Khan, Multan, Shahpur, Kohat, Peshawar, Lahore (2), Armitisar (1), Delhi (5), Rohtak, Sialkot, Ludhiana, Gurdaspur, and Jalandhar. Thus 13 districts of the Panjáb are noted for their cotton manufactures, and three of these possess power looms. Similarly the UNITED PROVINCES [9]—Benares, Bulandshahr, Sikandrabad, Azamgarh, Lucknow, Cawnpore (4), Mirzapore (1), Aligarh (1), Agra (3), Fyza-

bad, Rai Bareli and Rampur. CENTRAL PROVINCES [7]—Nagpur (2), Umrer, Bhandara, Burhanpur, Sambalpur, Chanda, Hinganghat (2), Jabbalpur (1), Pulgaon (1), and Raj Nandgaon (1). BERAR [2]—Badnera (1), Akola (1), and Ellichpur. RAJPUTANA AND CENTRAL INDIA [4]—Kota, Gwalior, Indore (1), Ujjain (1), Ajmir-Merwara (1), and Kishengarh (1). HYDERABAD [3]—Aurangabad (1), Hyderabad town (1), and Kulburga (1). BENGAL [10]—Calcutta (7), Howrah (3), Bardwan, Birbhum, Serampore, Nadia, Murshidabad, Jessore, Dinajpur, Rangpur, Bogra, Dacca, Tippera, Faridpur, Chittagong, Patna, Shahabad, Saran, Monghyr, Bhagalpur, Cuttack. ASSAM—Sibsagar and Manipur. BOMBAY [141]—Bombay City (84), Ahmedabad (32), Broach (4), Surat (3), Baroda (1), Veramgam (2), Wadhwan (1), Nariad (1), Julgaon (1), Bhavnagar (1), Hubli (2), Sholapur (3), Belgaum (2), Dharwar (1), Bijapur, Poona (2), Nasik, Thana Morui (1). SIND—Hala, Narapur and Karachi. MADRAS [17]—Madras town (4), Chingleput (Godavari), Nellore, Vizagapatam, Masulipatani, Salem, North Arcot (Arni), Coimbatore (1), Bellary (1), Tanjore, Madura (1), Pondicherry (5), Tinnevely (2), Tuticorin (1), Calicut (1), and Travancore (1). MYSORE [2]—Bangalore (2) and Shimoga. BURMA—A domestic industry only.

Sites for Factories.—The selection of sites for steam-power factories has been governed mainly by three considerations :—(1) proximity to supply of raw cotton ; (2) the existence of an indigenous industry and therefore of a community of professional weavers who might be drawn upon for labour ; and (3) facilities of transport to important markets. As indicated by the figures in the above enumeration, the modern power-loom industry has followed very much in the path of the ancient hand-loom craft. The fine muslins of Dacca, Arni, Chanderi, Kota, Rohtak, Benares and other localities are still being manufactured. Many writers speak of Dacca muslins as being a product of past ages. So long ago as 1820 Mr. Walter Hamilton, one of the Company's officials resident in Dacca, prophesied that with the decline and fall of the Delhi Court the loss of the fine muslins of Dacca might be expected, since the demand for these expensive fabrics very possibly would cease. But at the Delhi Durbar Exhibition of 1903 some remarkably fine muslins of Dacca were sold on behalf of the manufacturers—and these were very nearly as fine as the samples in the Calcutta Museum, which were procured in 1884 and made somewhere about that date. There is no very ancient sample of these muslins known anywhere, so that we have little by which to compare the famed ancient textiles with the modern productions. But the examples presently being turned out would measure 400's or 450's, while English power looms have been known to produce 600's. Cotton yarns are said to be counts of 20's, 30's or 400's, when not more than a like number of hanks of 840 yards go to the pound avoirdupois.

The point of interest in these Dacca muslins, however, lies in the fact that the hand spinners of Dacca are producing to-day yarns of a fineness that no machinery in the world could spin from the inferior staple which they use. Dr. Taylor wrote, in 1840, that the Dacca spinners failed to use the fine American cottons, and gave as their reason the fact that the English yarn swells on bleaching, while that of Dacca shrinks and becomes finer and stronger. It would thus appear that the European spinner, with all his beautiful machinery, may still have something to learn from the hand spinner, and that something might possibly lead to his being able to spin shorter staples than he at present considers indispensable. This hint seems worthy of careful investigation (see pp. 594-5, 607).

Special Indian Goods.—The artistic cottons produced in India are referable to two main heads—long cloths or damasks and muslins, plain or figured. The patterns are usually woven, not printed. When checked

they are in North India commonly termed *kheses*, to the South *gabrúns*: when striped they are *susís*. The usual colours are dark red for Hindus, dark blue for Muhammadans, in both cases interwoven with white. The *dhoti* or *dhotar* is worn by men and is a piece of plain cloth generally having a coloured border and measuring about 5 yards in length and $1\frac{1}{4}$ yards in breadth. It may be made locally or imported. The *sari* or woman's upper garment varies greatly according to the wealth, position, caste, etc., of the wearer as regards the material, quality or degree and nature of ornamentation. With finer materials it is usually a gauze, and is still very largely hand-loom work. The *sári* is, from an art point of view, perhaps the most picturesque of all Indian garments. The *chadar* or shawl is a sheet usually about three yards long and half as wide. It is worn by men, but by women of certain castes only. The *pagri* or *lungi* (turban) is a long narrow strip of cloth worn by men round the head or around the waist as a *cummer-band* (*kamar-band*). Mandelslo (*Travels*, in Olearius, *Hist. Muscovy*, etc., 1662, 27, 83) discusses the cotton manufactures of Broitschia (Broach) and of the "*comerbants*" or girdles of silk and fine cotton.

Throughout India certain localities are famed for the quality, design, etc., of their *kheses*, *gabrúns*, *susís*, *dhotis*, *saris*, *chadars*, *pagris* and *lungis*, etc. The merchant who may desire to open up a trade in manufacturing and supplying these special goods must ascertain the exact size and shape, the particular quality and colour in demand in each locality. The mere fact of offering a superior quality of goods is no inducement to trade. Few communities in the world are more conservative regarding their garments than are the various races and castes of India.

The figured or flowered muslins—*jamdanis*—are by far the most artistic of the cotton manufactures. These are literally cotton brocades, the patterns or flowers being formed by spools carrying special threads of cotton, silk, wool or gold, that are thrown by hand within the warp and thus become supplementary to the weft. The centres most famed for these artistic textiles are Dacca, Santipur, Chittagong, Tanda and Chanderi. The flowered muslins of Calcutta and Lucknow are needle-embroidered (*chickán*) work.

STEAM-POWER MILLS: Spinning and Weaving.—The first cotton mill founded in India was at Fort Gloster (the Bowreah Cotton Mills Company, Ltd.), near Calcutta. This received its charter in 1818 as a cotton mill, a coffee plantation and a rum distillery. Some years later the first of the Bombay series was established, namely the Bombay Spinning and Weaving Company (1851), and ten years later there were a dozen mills and 338,000 spindles at work. In 1879 the number had increased to 58 mills and 1,500,000 spindles, giving employment to 39,537 persons; in 1886-7 there were 90 mills with 16,926 looms and 2,202,602 spindles; in 1896-7, 155 mills, 37,303 looms and 3,984,023 spindles; and in 1901-2, 194 mills, 41,815 looms and 4,992,249 spindles. Within the decade ending 1901-2 the number of looms had increased by 69 per cent., and of spindles by 52 per cent. The capital invested in the 194 mills has been published as Rs. 16,01,40,384 *plus* £650,000; in 1904-5 they had still further expanded, namely to 203 mills with a capital of Rs. 15,97,41,301 *plus* £1,067,245, and had 47,305 looms and 5,196,432 spindles. In the *Moral and Material Progress of India* (1905-6, 176) the following statement occurs:—"There were at the end of 1905-6 in British India and Native

States 204 cotton mills containing 52,300 looms and 5,293,800 spindles, and giving employment on an average to 212,700 persons every day. Of these, 104 were exclusively spinning mills, eight were exclusively weaving mills, and in the rest both spinning and weaving were carried on. The capital invested, including an estimate for ten companies worked by private proprietors, for which accurate returns are not available, was £10,690,000 (paid-up capital and debenture loans). The industry is located, as regards 70 per cent. of the mills, in the Bombay Presidency, while there are 19 mills in the territory of Native States and in French possessions in India." Between the years 1893 and 1900 the industry was depressed, profits being affected by the disturbances in exchange relations with the Far East which followed the closure of the Indian mints, by over-production, by plague, by poor crops, by famine and by the disturbances in China. Since 1901 there has, however, been a satisfactory improvement. The Indian mills give permanent employment to 186,271 weavers, besides occasional employment to large numbers of cultivators, carters, boatmen, etc., etc. By way of comparison, it may be stated that in 1904 there were 2,077 mills in Great Britain; 1,201 in the United States; 500 in Italy; 420 in France; 390 in Germany; 304 in Russia and Poland; 257 in Spain; 203 in India; 64 in Japan; and 22 in Canada—the grand total of the world, including all others not specified, being 6,014 cotton mills.

Depression.

World's
Cotton Mills.

Wages of Indian Operatives in the Cotton Industry.—It would be impossible to furnish an average wage of all the employees in a mill that would be of any value, since the different classes of labour naturally command different wages. Still more impossible would it be to produce a figure or set of figures that could be regarded as applicable to the whole of India. The following returns taken from an actual statement given by the Government of India (in the publication known as *Prices and Wages*, 1906) are, however, highly instructive and indicate the average wages (piece-work and monthly wage, in Rs.) paid at the Manockjee Petit Mills of Bombay in January of each year from 1882 to 1906 :—doffer, in 1882 Rs. 5, in 1906 Rs. 6·5; winder, in 1882 Rs. 5 to 7, in 1906 Rs. 6 to 9; rover, in 1882 Rs. 14 to 16, in 1906 Rs. 12 to 15; reeler, in 1882 Rs. 5 to 7, in 1906 Rs. 7·5 to 9; warper, in 1882 Rs. 15 to 17, in 1906 Rs. 12 to 20; weaver, in 1882 Rs. 14 to 20, in 1906 Rs. 12 to 30; jobber, in 1882 Rs. 35 to 45, in 1906 Rs. 30 to 50. These are only a few out of the many, but they are sufficiently representative to show the wide range of wages earned, and to indicate the immense importance of the industry to a locality like Bombay that can lay claim to 79,270 men, 28,412 women, 13,590 young persons, and 5,883 children, a total of 127,155, all earnings wages on the scale indicated (the special cases mentioned), manifesting the highest, the lowest, and the medium class earners.

Wages.

TAXATION.—Cotton goods imported into India were for many years subject to a duty of 5 per cent. This tax existed, for example, before the date of the Mutiny and was continued when the East India Company ceased to exist. It was raised to 10 per cent., then in 1864 reduced to 7½ per cent., and in 1875 to 5 per cent. with lower rates for twists and yarns. But, by a Resolution of the House of Commons, 1877, it was ruled that these duties, being protective, should, as early as possible, be repealed. Accordingly, in 1882, the Indian import tariff was practically abolished and no fresh duties were levied until 1894. In March of that year import duties were charged on most articles except cotton goods. The omission of cotton was vigorously opposed by the Indian manufacturers, and a few

Taxation.

Imports

months later the bill was accordingly amended and certain cotton imports were excised. The cotton goods and yarns imported into India are mainly of the finer qualities, whereas those manufactured in India (chiefly on account of the inferior quality of the local staple) are of the lower grades. But with the medium-class goods, the foreign supply overlapped the local production, and hence, with a view to take away the protective character of the customs duty, it was decided to impose an excise duty of 5 per cent. on the medium qualities of yarn produced in India. Technically this is expressed by saying that all Indian-produced yarns above 20's were taxed. It was soon found, however, that this endeavour to equalise the burden of taxation on the two great competing sets of cotton manufacturers (Indian and Foreign) was not a success. In 1896 a further Act was accordingly passed by which cotton yarns were freed from taxation and a uniform duty of $3\frac{1}{2}$ per cent. imposed on all woven goods imported into India or manufactured by Indian power-loom mills, the village hand-loom industry being exempted. In 1902, B. J. Padshah wrote a *Memorandum on the Profits of the Cotton Industry of India and the Cotton Duties*, to which the editor of *The Times of India* contributed an Introduction: these papers will richly reward perusal. They may be accepted as setting forth present Indian commercial opinion. Padshah hinges the whole of his critical and very able review on two conceptions that he endeavours to disprove, viz. "that the average profits of the Mill Industry are high": "that the Cotton Duties would be really paid by the consumer of cotton goods and not by the producer." The net duty collected on the goods manufactured by the Indian mills for the four years 1901-2 to 1904-5 was, 1901-2, Rs. 17,77,965; 1902-3, Rs. 18,91,010; 1903-4, Rs. 20,95,149; and 1904-5, Rs. 24,06,976.

X. INDIAN TRADE IN RAW COTTON AND COTTON MANUFACTURES, BOTH LOCAL AND FOREIGN.

Trade in
Raw
Cotton.

RAW COTTON.—So much has already been said regarding the Indian Cotton Trade that this account may be fittingly drawn to a close by a few short paragraphs devoted to the more important sections under which transactions are ordinarily conducted. The total area (according to the *Final Memorandum* of the Commercial Intelligence Department for the year 1906-7) occupied by cotton was 14,918,000 acres in 1904-5, with

RAW COTTON

G YPIU
T A

a crop of 3,826,000 bales ; in the following year the corresponding figures were 21,072,000 acres and 3,426,000 bales ; and for 1906-7 they are estimated at 22,344,000 acres with 4,908,000 bales. These are the actual returns, as also the estimates for all India (British and Native States). In 1904-5 the yield of the British districts alone came approximately to 3½ million bales, while the exports and mill consumption together came to 3,390,413 bales. In 1905-6 the *Final General Memorandum* estimates the yield in British districts only at about 2,244,000 bales, while the mill consumption is said to have been 2,025,733 bales and the exports approximately 2,000,000 bales. Going back to previous years, in 1903-4 the acreage was 18,042,781, the outturn 3,168,113 bales ; the foreign exports were 7,931,075 cwt. (or 2,220,701 bales), thus leaving a balance (*plus* the produce of Native States) of 947,412 bales as available to meet local demands. But the scarcity of cotton in Europe, then prevalent, very possibly created a stronger demand for Indian cotton than can be regarded as normal. It may, therefore, be desirable to examine the returns of the year previous. In 1902-3 the crop was 16,581,046 acres, yielding 3,367,030 bales, and the exports to foreign countries 1,692,545 bales, thus leaving a balance to meet local demands of 1,674,485 bales, or exactly one-half the production. At the present day the hand-loom weavers rarely spin their own yarn, but purchase supplies either of the imported or of the Indian mill-spun yarn. It may thus be accepted that the balance of production over the demands of the Indian mills is available for the foreign markets.

Exports.—During the past seven years the following were the exports in cwts. and rupee values :—1900-1, 3,575,703 cwt. and Rs. 10,12,74,007 ; 1901-2, 5,700,014 cwt. and Rs. 4,42,60,933 ; 1902-3, 6,044,806 cwt. and Rs. 14,75,71,981 ; 1903-4, 7, 931,075 cwt. and Rs. 24,37,61,464 ; 1904-5, 5,657,743 cwt. and Rs. 17,43,46,872 ; 1905-6, 7,399,534 cwt. and Rs. 21,34,15,195 ; and 1906-7, 7,400,839 cwt. and Rs. 21,94,84,609. These figures thus show an average valuation of close on fifteen crores of rupees ; and if we assume an equal valuation for the share of the crop retained (well under the mark), the total value of the cotton raised in India would not be far short of thirty crores, or say £20,000,000.

Low Grade.—Reference has already been made to the degeneration that has taken place in the staple grown in India. The cultivators have allowed themselves to be driven into the production of an inferior staple or they have deliberately selected to grow that class of cotton. If the manufacturer would pay no more for a long than for a short staple, the Indian cultivators naturally sought out the plant that could give them the highest and most profitable yield. It is not surprising, therefore, that within the past thirty years or so the fine long-stapled cottons of India—the cottons that at one time were much admired and found a ready sale in Europe—have gradually disappeared, and that inferior but highly productive, early ripening and hardy races have taken their places (or are rapidly doing so). But the change that has come over the cotton industry may be spoken of as a consequence of various influences. The Indian mills having at hand an inferior staple, concentrated their attention on low-count yarns and inferior piece goods. So successful were they that in a remarkably short time they closed the Indian doors to imported goods of that class. England, on the other

hand, went in for long-staple cottons in order to produce high-grade goods. She found these in the United States, and thus gradually closed her doors against the short-staple cottons of India. But that inferior yarns might come to be refused both in India and China seems never to have been contemplated, yet it may now be affirmed that the future prosperity of the Indian cotton industry will turn very largely on whether or not the Indian cultivator can produce cotton superior and cleaner to that presently grown. With better-grade cotton it may in all fairness be said that it can be but a question of time when the Indian mills will claim a steadily increasing proportion of the supply of higher-count goods not only to India but perhaps to the world.

MANUFACTURES.—Local Trade in Yarn.—The *PRODUCTION* of yarn by the Indian mills (British and Native) has progressed steadily, but not phenomenally. The outturn (including Native States) in 1895–6 came to 432 million lb.; in 1900–1 it fell to 352 million; in 1902–3 rose to 575 million; in 1904–5 stood at 578 million; and in 1905–6 at 655 million lb., with in addition 25 million lb. produced by the mills located in the Native States. Of the amount for 1904–5, Bombay Presidency claimed as its share 422 million lb., being followed by Bengal with 38 million, Madras, 30 million, the United Provinces, 27 million, the Panjáb, 11 million, and lastly by the Native States with 22½ million lb. Of the total production in 1904–5 about 110 million lb. in the British districts and 4 million in the Native States were in higher counts, that is to say, qualities above 20's. This was about 10 million lb. in excess of 1903–4, and 43 million in excess of 1900–1. One of the most significant features of the modern traffic in Indian cotton manufactures is this increase of the outturn of the higher-count yarn, for which a fair amount of foreign raw cotton is being imported, and recently an increasing local production. In 1904–5, 192,544 cwt. of cotton were obtained from the United Kingdom, Germany, Egypt and the United States, etc., and in 1905–6 this supply stood at 161,476 cwt. The production of counts in 1904–5 was 51 million lb. in excess of that of 1899–1900. Attention has been drawn (in the *Review of Trade*) to the fact that the imports of high-count yarns have been almost in the inverse ratio to the expansion of the exports of Indian-produced yarns of that class (30's and over). By way of contrast with this prosperous Indian industry, it may be pointed out that the weight of twist and yarn imported in 1888–9 was 52½ million lb.; in 1898–9 it stood at 45½ million; in 1903–4 at only 28 million; though it rose again in 1905–6 to 45½ million lb.

Indian Yarn.—With regard to the *EXPORTS* of Indian twists and yarns, in 1876–7 these stood at close on 8 million lb., valued at 36½ lakhs of rupees; in 1903–4, at 252½ million lb., valued at about 9 crores of rupees (£6,000,000); in 1905–6 at 297½ million lb., valued at over 12 crores (£8,000,000); and in 1906–7 at 243½ million lb., valued at 10 crores (£6,931,021). Deducting these exports from the above-mentioned total production of yarn at the Indian mills, in 1903–4 there remained 303½ million lb. *plus* the foreign imports of, say, 28 million lb. of yarns, etc., as the amount to be worked up by the Indian power and hand looms; and in 1905–6 about 357½ million lb. *plus* the foreign imports, viz. 45½ million lb.

Piece Goods.—The woven goods produced by the Indian mills came to 95 million lb. in 1899–1900; 117 million lb. in 1902–3; 131 million lb. in 1903–4; 152 million lb. in 1904–5; and 156 million lb. in 1905–6, with in addition 7 million lb. turned out by mills in Native States. The

FOREIGN TRANSACTIONS

G YPIU
T A

manufactures are mainly grey unbleached; to be more exact, an average of about 83 per cent. are of that nature (126 million lb. out of the total 156 in 1905-6). The proportion of higher-class goods varies in the different provinces; in 1903-4 Madras showed 64 per cent., the Central Provinces 28 per cent., and Bombay 17 per cent. of their manufactures as white and coloured goods, hosiery, etc. It seems probable that the grey goods represent about four yards to the lb. in weight, so that in 1902-3 approximately 386 million yards of grey goods were produced by the Indian mills, 435 million in 1903-4, 524 million in 1904-5, and 540 million yards in 1905-6; while approximately 80 million yards of coloured, etc., were produced in 1902-3, 100 million in 1903-4, 108 million in 1904-5, and 112 million in 1905-6. The goods turned out at the Indian mills are *GREY*—described as *chadars*, *dhotis* (or *dhotis*), drills, *jaconets*, *madapollams*, *mulls*, printers, shirtings, sheetings (T-cloths). *FINER GOODS*—figured, coloured or miscellaneous goods and hosiery. Although the home market is likely for many years to be of primary importance to the Indian mills, the exports of Indian-woven cotton goods cannot be called unimportant. In 1903-4 the exports were valued at Rs. 1,63,07,648; in 1905-6 at Rs. 2,03,78,124 (= £1,358,541); and in 1906-7, Rs. 1,77,17,086 (= £1,181,139).

Exports of
Indian
Goods.

Foreign Trade.—Turning now to the *IMPORTS* from foreign countries—chiefly Great Britain—a traffic which constitutes nearly two-fifths of the whole imports taken by India. The trade in yarns, as already indicated, has declined. The piece goods are referred to the following chief groups:—Grey or Unbleached; White or Bleached; and Coloured, Printed or Dyed. India received in 1903-4, 1,085 million; in 1904-5, 1,210 million; in 1905-6, 1,348 million; and in 1906-7, 1,298 million yards of *GREY* piece goods. In 1903-4, 466 million; in 1904-5, 584 million; in 1905-6, 572 million; and in 1906-7, 494 million yards of *WHITE* goods. In 1903-4, 481 million; in 1904-5, 493 million; in 1905-6, 541 million; and in 1906-7, 524 million yards of *COLOURED* and printed cotton goods. These therefore totalled in 1903-4 to 2,032 million; in 1904-5 to 2,288 million; in 1905-6 to 2,463 million; and in 1906-7, 2,318 million yards; and the re-exports from these were in 1903-4, 66 million; in 1904-5, 63 million; in 1905-6, 67 million; and in 1906-7, 61 million yards, thus leaving in 1903-4, 1,966 million yards available for India; in 1904-5, 2,225 million; in 1905-6, 2,396 million; and in 1906-7, 2,257 million yards.

Imports,
Foreign.

Adding together the estimates of grey and coloured goods given above as the production of the Indian mills, we obtain the following:—466 millions yards in 1902-3; 535 million in 1903-4; 632 million in 1904-5; and 648 million in 1905-6. Deducting from these the exports to foreign countries, viz. 69 million yards in 1902-3, 75 million in 1903-4, 87 million in 1904-5, and 91 million in 1905-6, we arrive at 397, 460, 545 and 547 million yards respectively available for India; and adding these sums to the total imports also mentioned above, the grand totals become 2,448, 2,426, 2,833, and 3,016 million yards as the net Indian supplies for the years in question. This, in a population of 300 millions, allows each person to get about eight to ten yards per annum. It would thus seem that while the Indian mills are spinning very largely for China and other foreign markets, the looms are far more concerned with the home than any foreign markets. Hence but for the exports of raw cotton and the existence of power-loom mills, the Indian area of cotton cultivation would be reduced

Value of the
Indian Mills.

The Future.

to about one-quarter its present extent. That is to say, one-half the total production is exported raw and one-quarter in the form of yarn, thus leaving one-quarter to meet the existing local demands. The great feature of the future may be said to be the extent to which Indian manufactures of piece goods may curtail the imports from foreign countries, just as the production of yarn has most certainly curtailed imports of yarn from foreign countries into India.

[*Cf. Milburn, Or. Comm.*, 1813, i., 279-82; *Royle, Cult. and Comm. of Cotton in India*, 1851, 62-81; *Medlicott, Cotton Handbook for Bengal*, 1862; *Beaufort, Indian Cotton Stat.*, 1889; also *India's Trade in Cotton Goods and Yarns*, in *Indust. Quart. Rev.*, 1892; *Brooks, Cotton, etc.*, 1898, 240-354; *Imp. Gaz.* iii., 202-3, 281-2; *Rept. of the Chamber of Comm. Beng.*, 1903; *Austin, Cotton Trade of the United States and the World's Cotton Supply and Trade*, 1900; *Watkins, The Comm. Cotton Crops*, in *U.S. Dept. Agri. Stat. Bull.* 1904, No. 28; 1905, No. 34; *The Cotton Industry, Tariff Comm. Rept.*, June 6, 1905.]

D. P.,
vi., pt. i,
92-4.
Plumbago.

GRAP IT ; Ball, *Man. Econ. Geol. Ind.*, iii., 50-6; Holland, *Mem. Geol. Surv. Ind.*, 1900, xxviii., 126; 1901, xxx., 174; *Rec. Geol. Surv. Ind.*, 1905, xxxii., pt. 1, 51. Graphite consists almost entirely of pure carbon with a small proportion of iron. It is known also as Blacklead and Plumbago from its appearance, though lead does not enter into its composition.

Production.

A full account of the various localities where graphite has been found in India is given in the *Dictionary*, but though these are fairly numerous and scattered over a wide area, it is only in the State of Travancore that any progress in graphite mining has been made. Prospecting has also been attempted in the Godavari district, Madras Presidency, and in the Ruby Mines district of Upper Burma. According to Holland, regular returns were not available before 1901, but for the period 1901-3 the following records of production in Travancore are available:—1901, 2,490 tons; 1902, 4,575 tons; 1903, 3,394 tons.

Uses.

Graphite is used chiefly in the manufacture of pencils, crucibles, grate and iron-work polish, as a lubricator for machinery, in electrotyping, in the facings of moulds, etc., etc. In India the native mineral appears to be but occasionally utilised, and then only for polishing pottery.

D. P.,
iv., 177-4.

G WIA, *Linn.*; *Fl. Br. Ind.*, i., 383-93; Gamble, *Man. Ind. Timbs.*, 1902, 108-12; Duthie, *Fl. Upper Gang. Plain*, 1903, 109-17; Prain, *Beng. Pl.*, i., 281-4; **TILIACEÆ**. A genus of plants which contains about 60 species, 12 only being trees, the rest shrubs or climbers. Of these 36 are natives of India.

Fibre.

The species of *Grewia* are of little economic importance apart from the fact that the inner bark of most species yields a **FIBRE**, used in the manufacture of ropes and sometimes of paper. Some have a tough and close-grained wood, recommended for purposes where elasticity and strength are required. Accordingly the chief articles manufactured of these woods are banghy-poles, bows, axe and spear handles and the like. Dr. Bidie, in an article in *The Fishing Gazette*, 1897 (quoted in *Ind. For.*, 1897, xxiii., 148), remarks that the wood of three species, *G. oppositifolia*, *G. tiliaefolia* and *G. vestita*, should make excellent material for fishing-rods.

Timber.

Fruits.

The fruits of many of the species are edible. The most important are:—*G. asiatica*, *Linn.*, the *phalsa*, *shukri*, *dahmni*; wild in Central and South India, cultivated elsewhere. *G. elastica*, *Royle*, the *dhaman*; indigenous and planted from Hazara and the Panjáb Salt Range to Sikkim at 3,000 to 6,000 feet. *G. oppositifolia*, *Roxb.*, the *biñl*, *pastuwanne*, etc.; North-West Himalaya, from the Indus to Nepal, ascending to 6,000 feet. *G. tiliaefolia*, *Vahl.*, the *pharsa*, *khesla*, etc.; Sub-Himalayan tract from the Jumna to Nepal, ascending to 4,000 feet.; Central and South India; Upper Burma; low country of Ceylon. *G. vestita*, *Wall.*, the *dhamin*, *sealposra*, etc. Indigenous in the Sub-Himalayan tract from Dehra Dun to Assam; according to Gamble, common in *sāl* and similar forests. [*Cf. Pharmacog. Ind.*, 1890, i., 238; *Dodge, Useful Fibre Pl. of the World*, 1897, 187; *Woodrow, Gard. in Ind.*, 1899, 189; *Agri. Ledg.*, 1901, No. 9, 212; *Firminger, Man. Gard. Plants, 1903, i., 614; Cooke, *Fl. Pres. Bomb.*, 1904, ii., 66; COMPOSITÆ.
 Niger Seed and Oil. The *kálá-tíl*, *surgúja*, *rámtil*, *kernani*, *khurdsni*, *ulisi*,
valesulú, *huchchellu*, *gurellu*, etc. A native of tropical Africa, but cul-
 tivated as an oil-seed here and there in most of the provinces of India.

It is a *kharij* crop, sown from June to August and harvested in November or December. Rough and rocky laterite or light sandy soil is generally chosen, and the preparation of the land is very simple. Two ploughings before sowing are sufficient, and manure is not necessary. The seed is drilled in rows 11 to 13 inches apart, and 4 to 6 lb. per acre is held to be a sufficient seed rate. It is more commonly grown alone, but is sometimes accompanied by a pulse-crop. In Bengal a considerable portion of land is under this crop, especially in Chota Nagpur Division, but unfortunately the *Niger* seed is returned in the *Agricultural Statistics* under the general heading of "Other Oil Seeds," of which there are usually 500,000 acres, with 150,000 of these in Chota Nagpur. The "Others" are over and above linseed, rape, *til*, so that a fair proportion must be *nige*.. In Madras linseed and *til* (*Sesamum*) are separately returned, but a much larger area than both these put together is usually devoted to "Other Oil Seeds." In 1904-5 the "Others" came to 1,018,483 acres, of which 286,509 are in South Arcot; 111,594 in Anantapur; 92,461 in Cuddapah; 84,810 in Bellary; 71,351 in Karnul; 56,730 in Trichinopoly; 51,909 in Tanjore; and 47,215 in North Arcot, with lesser areas in the other districts. It is impossible to discover the exact proportions of these areas devoted to niger, but they must be considerable. In the United Provinces the acreage of "Other Oil Seeds" was in 1904-5, 113,731, and in the Central Provinces the corresponding figure was 314,716, of both of which a certain proportion would have been niger seed. Bombay is the only province that appears to give separate returns for the acreage of this oil seed. In 1905-6 (according to the *Season and Crop Report*) the total land used for it was 169,863 acres, of which Nasik had 68,940; Poona 22,843; Ahmednagar 14,764; Satara 16,026; Bijapur 7,960; and Ratnagiri 7,147 acres, etc. Rice (*Mysore Gaz.*, 1897, i., 123) gives an account of the niger seed in the various districts of Mysore, which the reader should consult.

When the crop is ripe it is cut near the root and stacked for eight days. It is then exposed for two or three days in the sun, then the seed beaten out with a stick and separated from fragments of the plant by a fan. The greater part is sold to the oil-makers for expression of the oil, the yield of which is about 35 per cent. of the weight of the seed. But the seed dries quickly and in England yields only about 16 gallons of oil per quarter of seed, while rape seed yields 20 gallons. The oil is pale yellow or orange in colour with little odour and sweet taste, more limpid than rape oil, with a specific gravity of 0.924 to 0.928. In its drying properties it ranks between cotton and linseed oil. For making paints, lubricating and lighting, this oil is useful, and in many parts of India is employed in cookery and for anointing the body: it is also frequently used as an adulterant for more valuable oils. It is said to be useful in cases of fracture and dislocation of bones among cattle. The oil-cake is highly appreciated in some parts of the country as a cattle food. In the English market the value of the oil is about 37s. per quarter. The production of this oil crop has suffered in recent years, like that of most other oils, through the remarkable expansion of the traffic in kerosene and other mineral oils and the by-products of these illuminants and lubricants. [*Cf. Basu, Agri. Lohardaga*, 1890, pt. i., 70; *Pharmacog. Ind.*, 1891, ii., 269-71; *Agri. Ledg.*, 1895, No. 24, 502; Hurst, *Lubricat. Oils, Fats, etc.*, 1896, 199; *Agri. GUTTA-P RC A.—Since Gutta-percha can hardly be characterised as an Indian product, it will be dealt with here very briefly. It is the commercial name for the inspissated milky sap of several plants of which nearly all (or at least all the important ones) belong to the natural

D. P.,
iii., 104- .
Gutta-
percha.

Different
Qualities.

order SAPOTACEÆ. The word "gutta-percha" is of Malayan origin: it signifies the gum or *gutta* or *getah* of the tree known as *percha*: according to some writers *percha* is also the ancient name of Sumatra, so that *getah-percha* would denote the *gutta* of Sumatra. And the true gum is to-day almost exclusively a Malayan product. As it reaches the market gutta-percha is, however, largely adulterated. There are high- and low-priced qualities as well as substances that more or less resemble gutta-percha, but which are adulterants rather than grades of *guttah*. The present article deals with both the pure gutta-percha and its substitutes.

Appearance in
Europe.

Uses.

Oxidises.

Gutta-percha first definitely appeared in Europe in 1845, and the discovery soon thereafter of its varied utilisations caused an immense demand. Dr. W. Montgomerie read a paper on it before the Society of Arts, London, from which date it became a regular article of trade. It is extensively employed in coating telegraphic cables, owing to its being a perfect insulator, while it is able to withstand in a remarkable degree exposure to varying atmospheric conditions. It keeps good for ten years, if exposed to the open air: 20 years, if protected in tubes; but 20 years, when submerged, have no appreciable effect upon it. Under the action of light, heat and air it slowly oxidises, becomes converted into a brittle resin soluble in hot alcohol. Chemically gutta-percha is almost identical with india-rubber (which see, pp. 647-60). It differs physically, being tough and inelastic. Since the date gutta-percha was made known to Europe perhaps no substance has developed more rapidly, and with india-rubber its uses may be said to be so many and so important as to make these two substances perfectly indispensable to commerce.

Imports into
United Kingdom.

Trade.—The immense demand has caused an extended inquiry all over the globe with the view of expanding the area of supply or of discovering useful substitutes. During the past seven years the imports of the United Kingdom alone have been:—1900, 126,059 cwt., £1,685,568; 1901, 88,438 cwt., £1,382,646; 1902, 83,889 cwt., £1,150,902; 1903, 46,411 cwt., £587,712; 1904, 27,288 cwt., £288,535; 1905, 45,434 cwt., £361,475; 1906, 53,271 cwt., £489,280. Of these quantities the Straits Settlements supplied from one-half to three-fourths of the total, but it would seem as if the supply from the Straits was decreasing while that from Venezuela, from British Guiana and from the Netherlands was expanding. It must not, however, be forgotten that a fairly large proportion of these imports are in gutta-percha substitutes, chiefly *Balata*. Burn-Murdoch (*Ind. For.*, 1905, xxxi., 309-20) has contributed useful particulars regarding the extraction, purification, properties, prices and traffic in gutta-percha, also a statement of the exports from Singapore from 1886 to 1903.

[*Cf. Solly, Observ. on the Prep. Caoutchouc*, in *Journ. Roy. As. Soc.*, 1840, ii., art. 2, 9-13; James Collins, *Journ. Soc. Arts*, 1885, xxxiii., 784; Burck, *Orig. Bot. de la Gutta-percha*, *Ann. Guide*, 1907, 138-9.]

A feature of the gutta-percha trade in which India is much interested is the possibility of some method being discovered by which the milky juices of certain abundant plants might be transformed into useful substitutes. The following may be given as the gutta-percha-yielding plants, as also those that it would seem desirable should in future be experimented with as gutta substitutes:—

Achras Sapota, Linn.; SAPOTACEÆ. The Sapota or Sapodilla tree. Is largely cultivated in Bengal for its fruit; yields the Mexican Chicle-gum. [*Cf. Journ. Agri.-Hort. Soc. Ind.*, 1844, iii., 147; Jumelle, l.c., 1903, 521-3.]

Alstonia scholaris, R. Br. (see p. 60); APOCYNACEÆ. The *chatwan*; is believed to be the source of *guttapulei* of Singapore. Hooper (*Rept. Labor. Ind. Mus.*, 1905-6, 29) found the latex to contain 45.1 insol., 41.8 resin and 13.1 ash. [*Cf. Manson, l.c.* 82.]

assia ottleyana, De Vriese; SAPOTACEÆ. A tree of Malacca and Borneo known as the *kotian*. The milk of this tree is regarded as an inferior quality of gutta-percha. Hooper (l.c., 1905-6, 27) says three samples of the milk of *B. latifolia* from Hoshangabad showed on the average 48.9 gutta, 38.8 resin and 12.3 per cent. ash. It was light grey, plastic, but the yield per tree small. A sample from Tinnevely of *B. longifolia* afforded 22.6 gutta, 62.7 resin and 14.7 per cent. ash (see pp. 116-20).

Calotropis gigantea and **C. procera**, R. Br. (see pp. 205-6); ASCLEPIADEÆ. The *madar* or *akanda*, abundant bushes all over India, have often been suggested as capable of affording a limitless quantity of milky sap. Whether that could be utilised profitably has not been definitely ascertained. Over the greater part of the Upper, Western and Central Provinces of India they cover many thousand square miles of waste land, and the utilisation of that herbage would be of infinite value to the people. [*Cf. Manson, l.c.* 87.]

uphorbia nerifolia, Linn.; EUPHORBIACEÆ (see p. 530).

• **oyleana**, Boiss. (see p. 531).

• **Tirucalli**, Linn. (see p. 531).

• **trigona**, Haworth—the *katti-mandu*. This shrub yields the cement *kattimandu*, often spoken of in connection with South India and the Deccan. It was specially recommended by Sir Walter Elliot in 1851.

1 **usops auki**, Linn.; *Fl. Br. Ind.*, iii., 549; SAPOTACEÆ. Is closely allied to if distinct from *M. Balata*, Gaertn., f.—a tree native in Guiana, Honduras and Brazil which affords a gum that is one of the best substitutes for gutta-percha (Jumelle, l.c., 1903, 493-517). No effort appears to have been made to discover whether any of the Indian species might similarly be of value. Other species are *M. Elengi*, Linn.—the Deccan to Malay Peninsula; *M. Roxburghiana*, Wight—South India; and *M. hexandra*, Roxb.—Deccan and Ceylon. But Gamble (l.c. 117) says that neither *M. Elengi* nor *M. Kauki* are in India known to yield gutta-percha. [*Cf. Manson, l.c.* 78.]

Palaguin elliptica, Engl., *Pflanzenr.*, iv., i., 135; *Bassia elliptica*, Dalz.; *Dichopsis elliptica*, Benth.; *Fl. Br. Ind.*, iii., 542; *Palaguin*, Brandis, *Ind. Trees*, 424-5; Manson, l.c. 77; Jumelle, l.c., 1903 457-85; SAPOTACEÆ. This is the *pauchoti*, *pauchonta*, *kat illupe*, *pala illupe*, etc. A large tree of the Western Ghats from N. Kanara southwards. It affords an inferior grade of gutta-percha, which is collected by tapping the living trees. Gamble adds, "but although this substance can be utilised for waterproofing and cement it is not a complete substitute for the proper article."

P. Gutta, Burch, in *Ann. Jard. Britz.*, 1885, v., 40; *Dichopsis Gutta*, Benth. & Hook., f., in *Gen. Pl.*, ii., 658; Gamble, l.c. 113-21. A tree of the Straits Settlements and Malay Archipelago, where it is known as *taban merah* (in Perak), *niato balam tembaga* (or *abang*) in Sumatra, and is the source of the finer grades of the gutta-percha of commerce. But there would appear to be many qualities of the gutta obtained from this plant, some of which are apparently the produce of distinct varieties, others the results of different methods of preparation, and

D. P.,
i., 0.

D. P.,
v., 25 -3.

D. P.,
iii., 10 -3.

D. P.,
iii., 103-4.

still others indicate varying degrees of adulteration. For example the *taban merah* (according to Burn-Murdoch—the most recent writer) is *P. oblongifolium*; *taban chaiser* is *Palaquium* sp.; *taban puteh* is *P. pustulatum* and *taban baik* is *P. sp.* The *taban puteh* is much inferior to the others. On the other hand, while *P. oblongifolium*, Burch, is but a variety of *P. Gutta*, still by certain writers it is held to be a distinct species and to yield the *taban sutra* of Perak,

Gamble (*Man. Ind. Timbs.*, 445) says, "The method of collection, usually employed by the Natives of the Malay Peninsula, is very simple but very wasteful. The tree is felled, and either the bark is stripped off altogether or rings are cut at intervals of about a foot. The sap that oozes out is then collected, put in a pot and boiled with a little water, which prevents its hardening afterwards when exposed to the air. It is then run into moulds. The trees usually chosen are those of about thirty to thirty-five years old, and each tree gives 2 to 3 lb. of gutta. Such a system is naturally a wasteful one, and if regularly continued without any arrangements for reproduction would probably lead to the exhaustion of the supply, so that it is satisfactory that French experts are said to have discovered that the gutta-percha can be obtained from the leaves without felling the tree. However this may be, there is little doubt of the value of the product, and that if it is to be regularly produced the tree must be grown in plantation and systematically worked."

P. polyanthu, Engl., *Pflanzenr.*, iv., i., 135; *Isonandra polyantha*, Kurz; *Dischopsis polyantha*, Benth. & Hook., *Gen. Pl.*, ii., 658. A moderate-sized tree of Cachar, Chittagong, Arakan and Pegu. This is the *tali*, *sill-kurta*, *thainban*, etc. Kurz says it yields a good quality of gutta-percha and in large quantity. [*Cf. P. obovatum*, King and Gamble, in Hooper, *Rept. Labor. Ind. Mus.*, 1905-6, 27.]

13. *Payena lucida*, A. DC.; *Isonandra polyandra*, Wight, *l.c.*, t., 1589; *Fl. Br. Ind.*, iii., 547; Gamble, *Man. Ind. Timbs.*, 449; SAPOTACEÆ. The *dohu-kurta* of Cachar is an evergreen tree of Assam, Tenasserim and the Straits Settlements. *P. Maingayi*, Clarke, a tree of Penang and Malacca. Both these trees afford gutta-percha; the last mentioned, according to Maingay, abounds in that substance.

P. Leerii, Burch, *Rapport Gutta*, 1884; also *Orig. Bot. de la Gutta-percha*, in *Ann. Jard. Bot. Buitz.*, 1885, v., 56, pl. viii.; *P. Leerii*, Engler, *Pflanzenr.*, 1889, iv., pt. i., 133, with plate. Kurz rightly transferred *Kertophorus Leerii*, Hassk., to *Payena* (*Journ. As. Soc. Beng.*, 1871, xl., 69), but his Burmese plant is apparently a different species from that of Malacca, Sumatra, Borneo, Banka and Amboina, to which the name *P. Leerii* strictly speaking belongs. Kurz accordingly would seem to have desired to correct his mistake when (in *Journ. As. Soc. Beng.*, xlv., 230) he subsequently gave the Mergui plant the name *P. paratetoneura*, Kurz. Hooper found that the Burmese plant contains 59·9 per cent. gutta and 39·6 per cent. resin. *P. Leerii* proper yields the *sundek* of Perak and the *niato balam baringin* (or *soendi*) of Sumatra—a trade quality of gutta-percha. [*Cf. Jumelle, l.c.*, 1903, 486-92; Hooper, *Rept. Labor. Ind. Mus.*, 1905-6, 27-8; Mason, *l.c.* 78.]

Medicine.

ID MU INDICU, Br.; *Fl. Br. Ind.*, iv., 5; Prain, *Beng. Plants*, 1903, ii., 686; Cooke, *Fl. Pres. Bomb.*, 1904, ii., 146; AS-
CLEPIADEÆ. Indian (or country) Sarsaparilla; *anantamul* (*anantvel*), *magrabu*, *sugandi pālā*, *nannari*, *uparsāra*; *sārivā* (Sanskrit). A climbing plant of North India, from Banda to Oudh and Sikkim, and southward to Travancore and Ceylon.

The root has long been employed in Native medicine. Garcia de Orta (1563, *Coll.*, xlii.; also in Ball, *Proc. Roy. Ir. Acad.*, 1890, 3rd. ser., i., 656) speaks of a thorny climber which resembles the pomegranate, from the wood, bark and root of which a drug is obtained. Ball regards that passage as possibly denoting *emidesmus*, but is it not rather *Smilax*? The root is supposed to possess properties allied to those of sarsaparilla, and from 1864 has been official in the British Pharmacopœia. It is prescribed usually in the form of syrup and is demulcent, alterative and diuretic. Sometimes the whole plant is pounded and a congee made with rice, or an infusion prepared of the dried leaves. In Indian commerce *anantamul* is found in the form of little bundles, which consist

MUSK MALLOW AND ROZELLE

I I CU
TILIAC U

of the entire roots of one or more plants, tied up with a portion of the stem. *Anantamul* costs 6 to 8 annas per lb., and in Europe appears to sell at 1s. 6d. to 2s. per lb. [Cf. *Pharmacog. Ind.*, 1891, ii., 446-9; De Silva, *Indig. Food Prod.*, *Trop.*, *Agrist.*, 1891-2, xi., 520-1; Waring, *Baz. Med.*, 1897, 72-3; Dutt, *Mat. Med. Hind.*, 1900, 195-6; *Rept. Cent. Indig. Drugs Comm.*, 1901, i., 124, 153; *Rec. Bot. Surv. Ind.* (many passages); White and Humphrey, *Pharmacop.*, 1901, 224.]

I I CU, *Medik.*; *Fl. Br. Ind.*, i., 334-44; Cooke, *Fl. Pres. D. P.*, *Bomb.*, 1901, ii., 104-14; Duthie, *Fl. Upper Gang. Plain*, 1903, 87-93; *iv.*, 22 -48; Prain, *Beng. Plants*, i., 262-9; Wiesner, *Die Rohst. des Pflanzenr.*, 1903, ii., 221-2; MALVACEÆ. A genus of herbs, shrubs or trees, which embraces about 150 species. Some 33 are indigenous to India and several others have been introduced, and are now cultivated widely. Many are of considerable economic value, one an important vegetable, and another produces a fibre that is extensively used as a substitute both for hemp and jute.

. *Abel oschus*, Linn.; *Rec. Bot. Surv. Ind.*, iii., 178. The Musk Mallow, *mushk-dáná*, *kalkastari*, *kasturi-bhendí*, *latá kasturiká*, etc. A herbaceous bush, common throughout the hotter parts of India. It yields a fibre which occupies a high place among those of the jute type. The seeds afford an odorous principle employed in perfumery as a substitute for musk. In European trade they are known as *GRAINS D'AMBRETTE*. By the Natives of Northern India they are employed medicinally. Their value varies from about 4d. to 1s. per lb. [Cf. *Pharmacog. Ind.*, 1890, i., 209-10; *Agri. Ledg.*, 1896, No. 6, 29-31; 1898, No. 15, 505; Mukerji, *Handbook Ind. Agri.*, 1901, 329-30; Schimmel & Co., *Semi-Ann. Rept.*, Oct. 1902, 9.] Musk allow. Perfumery. Price.

. *ficulneus*, Linn.; *Rec. Bot. Surv. Ind.*, iii., 28, 178. The *ban dhenras*, *janglí bhindí*, *kapasiya*, *dula*, etc. A prickly herbaceous annual, indigenous in the hotter parts of India, from the Panjáb and Bengal to South India and Ceylon. The stem yields a long, glossy, white and strong fibre, useful for twine and light cordage. Fibre.

. *rosa-sinensis*, Linn.; Woodrow, *Man. of Gard.*, 1899, 179; Firminger, *Man. Gard. Ind.* (ed. Cameron), 651; *Rec. Bot. Surv. Ind.*, ii., 40, 84; iii., 179. The Shoe Flower, *jasút*, *juwa*, *joba*, *jasavanda*, etc. An ornamental shrub, native of China, but found in most gardens in the plains of India. The bark yields a fibre. The flowers are said to produce a purple dye, and are also used in Native medicine. The roots are employed in Mysore in certain cattle diseases (*Journ. Bomb. Nat. Hist. Soc.*, 1892-3, vii., 512-5). hoe Flower. Fibre. Dye.

. *Sab ri a*, Linn.; Woodrow, *l.c.* 183; *Rec. Bot. Surv. Ind.*, ii., 40, 84; iii., 28, 179; Firminger, *l.c.* 288. The Rozelle or Red Sorrel of the West Indies, *mesta*, *patwa*, *lál ambári*, *kempu*, etc. A small elegant shrub, widely cultivated throughout the hotter parts of India and Ceylon. The seeds are sown about the end of May, and the plants put out in the ground at a distance of 4 feet from each other. The gathering may be made in November or December in Bengal, but rather earlier in the upper provinces. It seems to thrive best in the damp climate of Lower India and cannot be cultivated on the hills. ozelle. Seasons.

The stems yield a strong, silky fibre, the Rozelle Hemp of commerce, obtained by retting the twigs when in flower. The seeds are used in medicine, and have demulcent, diuretic and tonic properties. The fruit, or rather fleshy calyx, is a valuable antiscorbutic, largely eaten in the form of jellies, chutnies and other preserves. The leaves are eaten as salad and in Native curries. [Cf. *Pharmacog. Ind.*, i., 212; Dodge, *Useful Fibre Plants of the World*, 1897, 196; *Imp. Inst. Tech. Repts.*, 1903, 96.] Fibre. Medicine. Jelly.

. *aceus*, Linn.; Gamble, *Man. Ind. Timbs.*, 1902, 87; *Rec. Bot. Surv. Ind.*, ii., 177, 245, 247, etc.; iii., 179. The *bola*, *baniá*, *belli-pata*, *chelwa*, *thinban*, etc. A small tree or bush of the sea-coast forests and long tidal rivers all round India, Burma and Ceylon. It yields a fibre of fair quality, which can be readily separated and does not easily rot under water. In Bengal it is used for making rough ropes, in the Sundribans for cordage, and in Ceylon for mats. Gamble remarks that it ought to be useful for paper. Ma on (*Ind. For.*, 1905, xxxi., 347-50) gives an account of experiments which have recently been made in Burma with this fibre as a jute substitute. He considers it would probably fetch about £12 per ton, if sent to market in the condition that jute usually Fibre. Paper. Jute Substitute.

umber.

appears, though fibre collected in the Toungoo district of Burma and prepared by Mr. Le Fevre is said to have realised as much as £35 per ton in England. The wood is used only for fuel, and occasionally for hut-building (see *ats* d atting, p. 776). [*Cf. Yates, Text. Antiq.*, 1843, 304-6; *Text. Journ.*, Oct. 1890; Dodge, *l.c.* 197.]

Deccan
 Hemp.

H. c n binus, *Linn.*; Roxburgh, *Trans. Soc. Arts.*, 1804, 382; 1806, 152; also *Coromandel Pl.*, ii., 190; *Rec. Bot. Surv. Ind.*, i., 90, 194; ii., 40, 84; iii., 179; Sprague, in *Kew Bull.*, 1908. Deccan Hemp, kanoff, ambari hemp, *ambári*, *ambadi*, *pulu*, *mesta pát*, *dare kudrum*, *pátsan*, *sheria*, *pundi*, *gogu*, *sujjádó*, etc. A small herbaceous shrub, indigenous in Africa and introduced into India, now cultivated extensively for its fibre.

Cultivation.

The cultivation, both as a crop and as a hedge plant, is largely carried on in Bombay (especially the Deccan and KarnátaK), the Central Provinces and Madras. Elsewhere to a much smaller extent—Bengal, chiefly Chota Nagpur; also here and there in the United Provinces and the Pan-jáb.

Distribution.

The Bombay statistical returns for 1905-6 show an area of 83,109 acres, with 16 acres in Sind, and an average of about 90,000 acres annually. Rocky and laterite soils which are not suitable for jute are well adapted for the cultivation of *ambari*. It grows best on the alluvial soils of North Gujarat, but does also very well in medium black soils. It is usually grown as a mere sprinkling among other crops, and the tillage is the same as that of the crop with which it is associated, especially *bajra* and *juar*. In October-November the plants should be uprooted. Full-grown plants which have ripened their seed furnish stronger fibre than if cut while in flower. The small bundles of stalks, when dry, are tied into large bundles and steeped in water for some ten days. If the fibre is separated in the cold weather, longer steeping is required. When removed the bark and fibre readily peel off in strips from the root upwards. The strips are then beaten with a stick and threshed in water till the clean fibre is separated. It is bright and glossy, but coarse and harsh. The length is 5 to 10 feet, and the breaking strain has been variously stated at 115 to 190 lb. Hanausek (*Micro. Tech. Prod.* (Winton and Barber, transl.), 1907, 83) gives interesting particulars of the microscopic structure of this fibre.

Season.

Fibre.

Retting.

Properties.

Ropes and
 Cordage.
 Canvas.

The Deccan hemp is spoken of as similar to jute, but very much superior. In India a coarse sackcloth is made from it, though its chief utilisation is for ropes and cordage. Coarse canvas is also manufactured from it, and in Bengal it is employed for all purposes for which jute is in demand, but being more durable it is used for fishing-nets and paper manufacture. *Ambari* hemp is stated to be worth about 8 lb. per rupee, but no statistics regarding the extent of the trade are available.

A few years ago a fibre appeared on the London market under the name of Bimlipatam jute, which there seems little doubt was Deccan hemp. Still more recently a new fibre from Rio de Janeiro has been much advertised under the name of Canhamo, and this has been shown by Sprague to be obtained from an allied species, *H. radiatus*, *Cav. (Fl. Br. Ind.*, i., 335). Thus for commercial purposes both the Bimlipatam jute and the Canhamo hemp may be accepted as possessing the same properties as the fibre of *H. cannabinus*.

Bimlipatam
 Jute.

The demand for Bimlipatam jute is stated to be yearly increasing, and in 1903-4 the exports to London amounted in value to two lakhs of rupees. On the London market it is worth from £11 to £12 12s. 6d. per ton.

Dunstan's chemical investigations into the properties of this fibre, published in the *Imperial Institute Technical Reports*, as also the further particulars afforded in *The Agricultural Ledger*, will be found useful and interesting. Apparently the samples of Bimlipatam jute were found of lower value than the best Bengal jute. In the subsequent investigations into this fibre it was found to be prepared on an extensive scale in a factory at Chittavalsa in Vizagapatam, as also exported from Bengal to some extent under the name of *mesta pát*. Comparing a sample of true jute with an authenticated sample of Deccan hemp and a good average specimen of Bimlipatam jute, it was found that the percentage of cellulose was nearly the same in all three. The last two were superior to ordinary jute in the smaller loss in mercerising and the larger increase in weight on nitration. The reports therefore conclude that Bimlipatam jute (*i.e.* Deccan hemp) is deserving of attention.

The seeds yield a clear and limpid oil, and have been sent to England as an OIL-SEED. They are used in Poona as a cattle food, and the leaves are eaten as a VEGETABLE.

The Edible Hibiscus, Lady's Fingers; ochro or okra, of the West Indies, *bhindi*, *dhenras* (or *dheras*), *rámturnai*, *bendekai*, *vendaik-kay*, *youn-padi-si*, *tindisa*, etc. A tall herb, cultivated throughout India and naturalised in all tropical countries. De Candolle regards it as of African origin.

It is largely cultivated by the Natives of India as a garden crop for the sake of its FRUIT. It should be sown from April to June in nurseries, and transplanted when about 3 inches high. Weeding should be done regularly all through the period of growth to keep the soil loose and open. As a field crop successful cultivation largely depends on rich manuring of the soil. Two varieties, an early and a late, are grown in Bombay, both being sown in June. The acre rate of seed varies from 5 to 10 lb. and the seed is sown at intervals of about a foot, on ridges three feet apart. The early variety bears fruits from about August to September, while the late does so from the end of September to November.

In Madras, the early crop is sown in the first week of March and gathered in the first week of July; the late crop is sown in the latter part of July and gathered in towards the end of December. The yield of fruit per acre varies from 5,000 to 6,000 lb. The cost of cultivation is said to average about Rs. 5 per acre, and the profit about Rs. 9. The bast yields a white FIBRE which is long, silky, strong and pliant, and composed of fine individual threads. The breaking strain is 79 pounds dry, and 95 wet. In colour and texture it resembles hemp, and is well adapted for making ropes, twine and sacking, while the residual portions might be utilised for paper-making. There are no statistics of trade in ochro fibre: it is apparently sold only as an adulterant of jute or of

Hides and
kins.

ID , KIN , L A T H E R d the M n u f c t r e
therefr.—The term "*Hides*" denotes commercially the raw, dressed or tanned skins of full-grown cows, bullocks, buffaloes and horses, etc., while "*Skins*" is applied to those of calves, sheep, goats, deer and other wild animals. The term "*Fur*" is used for ornamental skins, with the hair or wool attached.

Furs.

It may, perhaps, be as well to dispose at once of the least important group, namely, the "*Furs*." In addition to the skins of Deer and Antelopes, there are returned under "*Furs*" (*D.E.P.*, iii., 458) some 70 different fancy or ornamental skins that are occasionally met with in trade. The following are some of the more important (mentioned in alphabetical sequence):—*Cynecturus jubatus*, the Hunting Leopard; *Felis pardus*, the Leopard or Panther; *F. tigris*, the Tiger; *F. uncia*, the Snow Leopard; *Mustela*, two species, the Martens; *Putorius erminea*, the Ermine or Stoat; *Sciurus*, the Squirrels; *Vulpes*, the Foxes; and *Ursus*, the Bears; etc. It would seem that in India some of the smaller skins, such as dog-skins, snake and lizard skins, mole-skins, frog-skins and the like are utterly neglected, a consequence very possibly of the climate and the defective methods of curing presently practised.

Chief Kinds.

Trade.
Stock.

RAW HIDES AND SKINS.—Supply.—Under Live stock (pp. 732-52) will be found mention of the chief wild and domestic species and races of animals, the skins of which appear under **Hides and kins**. It is not necessary to enumerate these again, but it may be useful to state once more that the live stock of India cannot be far short of a grand total of 220 millions, of which perhaps 40 per cent. die or are slaughtered annually. The annual average exports to foreign countries at all events were, for the five years ending 1903-4, Hides (raw and tanned) 12½ millions; Skins (raw and tanned) 37 millions, or 23 per cent. of the estimated total stock. But these returns take no cognisance of the hides and skins used up in India nor of the animals that die or are killed, but of which the hides and skins are not preserved.

Annual
Supply.
Exports.

Local
Trade.

Total Transactions.—It would not be far from correct to affirm that India's local manufactures in skins and leather are as valuable as her foreign trade in these commodities (raw and manufactured). In 1876-7 the total of the declared values of the imports and exports, taken together, was Rs. 3,13,77,912 (or say £2,091,860); in 1902-3 the corresponding figure was Rs. 9,27,48,853 (or say £6,183,257); and in 1903-4 the total traffic came (less the re-exports) to Rs. 9,71,04,548 (or say £6,500,000). If the idea of the internal trade being approximately as valuable as the foreign can be accepted as fairly correct, then during 1903-4 the total turnover of the industries here dealt with (exports *plus* consumption) would have been close on a valuation of £13,000,000. And later figures for 1906-7 show a considerable expansion, viz. to a total

(imports and exports, less re-exports) of Rs. 15,94,66,392 (or £10,631,093), and thus of an estimated total traffic of over twenty-one millions sterling.

Fluctuations.—But there are a few aspects of importance that had better be here indicated. For example, the trade in hides and skins, as also the craft in leather manufacture, are in the hands either of Muhammadans or of low-caste Hindus. They are, therefore, participated in by a comparatively small community. So again the workers in skins, hides and leather are in Northern India collectively designated *chirmjarosh*. Then there are two main classes of hides and skins:—*hallali* (slaughtered), *murdari* (dead). The former come from the slaughter-houses of the cities, the latter from the country. The *chumars* (the special caste of skimmers) wander about all over the country, and make it their business to skin dead cattle. In seasons of scarcity and famine they reap a rich harvest, but it is often affirmed that they are unscrupulous and, when they do not obtain a sufficient supply, that they are not averse to systematically poisoning cattle. With them, in fact, cattle-poisoning is held to be a profession, and to have attained the position of a high art (see *Abrus*, p. 1). Moreover, it is believed that a large proportion of the cattle that perish in India die from preventable causes, such as neglect, drought and murrain. The loss to the country of a large percentage of its cattle far outweighs the total value of the traffic in skins and hides, so that the increasing exports in these articles are only too frequently the most certain indication of widespread suffering and loss. The traffic in hides and skins is accordingly subject to great fluctuations, concomitant with the vicissitudes of the seasons. The famine in Western India, during the years of 1899–1901, caused the traffic to become abnormally high, especially in untanned hides, but, due to the war in South Africa, the prices were at the same time preserved. The exports for each of those years were nearly double the normal traffic, but the demand was, nevertheless, brisk. The difficulty to procure capital—an ever-present cause of obstruction to all manufacturing enterprise in India—is doubly true of the leather trades. Religious objection assigns it a position of degradation and neglect. It became accordingly a monopoly within a restricted community, and thus not only suffers from want of capital but from the loss of invigorating competition and popular interest and favour.

Foreign Trade.—The exports to foreign countries from the chief seaports of India are drawn from the provinces by rail, road and river, as also coastwise by sea. These may be analysed as follows:—

Railborne, etc.—Unfortunately a difficulty is at once presented, viz. the railborne and the coastwise transactions are recorded in cwt. It is thus next to impossible to obtain a factor by which to reduce these to numbers of hides as in the returns of foreign trade, since the goods vary so greatly according to species of animal, size and condition, nature of curing or tanning pursued, etc., etc. The figures as they stand are, however, relatively of value:—During 1906–7 the railways of India carried 2,517,787 cwt. of hides and skins (raw and tanned), the bulk being raw. Of that large amount 1,126,302 cwt. were conveyed to CALCUTTA and were drawn—from Bengal Province, 350,953 cwt.; from the United Provinces, 354,804 cwt.; from the Panjáb, 103,855 cwt.; from the Central Provinces and Berar, 57,056 cwt.; from Madras, 13,974 cwt.; from E. Bengal and Assam, 232,036 cwt.; from Rajputana and Central India, 7,623 cwt.; and from Bombay, 4,816 cwt. The next most important receiving centres are the MADRAS PORTS, which, in the year in question, drew 520,856 cwt., namely from the Madras Presidency, 330,512 cwt.; Mysore, 38,398 cwt.; the Nizam's Territory, 44,951 cwt.; Bombay, 56,901 cwt.; Central Provinces,

20,705 cwt.; Panjáb, 19,289 cwt.; and from the United Provinces, 5,441 cwt. MADRAS PRESIDENCY is third in importance with 217,674 cwt., derived chiefly from Mysore, 77,677 cwt.; from its own port towns, 61,434 cwt. from Bombay (5,518 cwt.); from the Nizam's Territory (29,968 cwt.) BOMBAY PORT takes the fourth position with a supply of 149,048 cwt., derived chiefly from its own Presidency, 68,823 cwt.; Panjáb, 28,765 cwt.; United Provinces, 23,419 cwt.; Central Provinces, 13,272 cwt.; Madras, 5,462 cwt. Then comes KARACHI with 139,107 cwt., derived mainly from the Panjáb, 100,404 cwt.; Sind, 37,385 cwt.; and from the United Provinces, 842 cwt. Lastly the PANJÁB with a total supply of 113,973 cwt., derived chiefly from Rajputana and Central India, 32,978 cwt.; and from the United Provinces, 58,782 cwt. Looking at these figures from the point of view of EXPORTS, the Bengal Province supplies 357,794 cwt.; the United Provinces 464,376 cwt.; Madras 368,127 cwt.; the Panjáb 296,576 cwt.; Bombay 171,746 cwt.; Mysore 117,866 cwt.; Rajputana and Central India 118,613 cwt.; Central Provinces and Berar 122,774 cwt.; the Nizam's Territory 86,183 cwt.; Sind 54,559 cwt.; and E. Bengal and Assam 234,810 cwt. Thus, so far as the foreign trade is concerned, the supplies come mainly from Bengal and the United Provinces. Cawnpore is the great emporium of leather production in India, and the supplies of hides and skins procured by the tanneries of that town must be very largely drawn from local supplies, seeing that the imports are comparatively unimportant. This fact necessarily raises the United Provinces into the position of greatest importance in the hide trade.

Coastwise.—Turning now to the coastwise transactions, it is ascertained that the total IMPORTS of raw hides do not normally exceed 25 to 30 thousand cwt., valued at 10½ lakhs of rupees; of raw skins about 15 thousand cwt., valued at 7½ lakhs of rupees; and of dressed and tanned hides and skins about 6½ thousand cwt., valued at 6 lakhs of rupees.

Exports.—In the *Review of the Trade of India* for 1904-5 it is shown that, according to the declared values, the prices of hides rose steadily during the preceding four years, the average price for 1904-5 being 11·4 per cent. in excess of that for the previous year. The corresponding price of skins, on the other hand, fell 13·1 per cent. The number of raw hides and skins exported collectively came to 31,606,246, valued at Rs. 7,05,35,585—the shares being 8,722,520 hides and 22,883,726 skins. The value of the raw-hides exported from Calcutta was 84·6 per cent. of the total trade. They were consigned to the Continent mainly, Germany taking 144½ lakhs; Italy 66 lakhs; Austria-Hungary 51½ lakhs; and Spain 22½ lakhs. This left 23 lakhs consigned to the United Kingdom, and 40½ lakhs to the United States. Calcutta also contributes 75·6 per cent. of the total value of the foreign exports in dried and pickled skins. About the same percentage (in value) of the foreign exports is usually drawn from India by the United States. Of the balance, France claimed 29½ lakhs, and the United Kingdom 25½ lakhs. The demand in France seems to be increasing. The later *Review* for 1905-6 states that the price of hides continued to rise, the average value per cwt. increasing from Rs. 52-4-8 in 1904-5 to Rs. 55-7-0; while that of skins continued to fall, viz. from Rs. 91-1-6 per cwt. in 1904-5 to Rs. 90-7-1 per cwt. The number of hides and skins exported in 1906-7 collectively came to 39,806,281—the shares being 12,917,227 hides and 26,889,054 skins.

TANNED HIDES AND SKINS.—The most significant feature of the coastwise returns, abundantly confirmed by most statistical statements of the Indian trade in hides and skins, may be said to be the fact that Madras is by far the most important centre for dressed skins, and that Burma is the chief coastwise market for them. Recently, however, Bengal has begun to participate largely in this Burmese supply. After Burma, Bombay affords the next most important local outlet for Madras

dressed skins. And this position of importance held by the Madras Presidency in the traffic in dressed and tanned skins and hides is still further borne out by a study of the foreign trade. During 1904-5 Madras furnished 91 per cent. of the dressed hides and 73 per cent. of the dressed skins, Bombay following with a fair proportion of the balance. The United States of America have hitherto been the most important market for Madras dressed skins. But within the past few years an unhappy new manifestation has appeared, namely a decline in the demand for Indian dressed skins. The export traffic in dressed goods has recently, in fact, fallen back, and the demand for Bengal raw skins advanced considerably. This is presumed to be a direct consequence of the cheaper and more efficient methods of tanning (especially that known as the chrome process) now largely practised in the United States. It points to the urgent necessity for Indian manufacturers to advance with the times or face the total loss of their trade. The tanner who pursues crude methods and continues to employ defective appliances can no more hold his own against the cheapening process of scientific progression than the hand-loom cotton weaver can stem the tide of steam-power prosperity.

Market.

A Change in
Character of
Exports.

Progress
Essential.

Exports.—The decline in the traffic in tanned hides and skins, established within recent years, calls pointedly for serious consideration. The so-called tanning of India, given to the hides and skins exported, was, and is at its best, so imperfect and unsatisfactory that retanning in the countries to which consigned was essential. But however crude it may be, the business is by no means an unimportant one, nor one for which an effort should not be made to save it from complete annihilation. In 1900-1 the exports of tanned hides were valued at Rs. 1,46,80,048, and of skins at Rs. 3,02,61,805, or collectively Rs. 4,49,41,853 (close on three million pounds sterling). The next year, 1901-2, the collective exports of tanned hides and skins were valued at Rs. 2,65,40,461; in 1902-3 they were Rs. 2,89,81,866; in 1903-4, Rs. 3,09,88,759; in 1904-5, Rs. 2,85,17,173, or approximately one-half the value of the traffic five years previously. Commenting on this somewhat significant state of affairs, Mr. J. E. O'Connor wrote, "This transference of the trade from tanned to untanned skins is likely to proceed in an accelerated degree, to the great loss and detriment of the trade in the Madras Presidency. But it must not hastily be concluded that in itself the contraction of this industry is a subject for regret. If the industry had been established on a sound economic basis, it would not and could not have suffered, for all the natural conditions are in its favour, including cheap and abundant supplies on the spot of skins and tanning substances and cheap labour. These advantages, however, were not effectively utilised, in consequence of the absence of capital, for tanning is essentially an industry in which the possession of large resources counts for much." "The position, however, may be rectified without difficulty if capital is forthcoming; and if it is desired to prove that tanning is a profitable industry, it may be observed that where it has been undertaken in accordance with sound principle, as in the leading tanning establishments in Cawnpore and Bombay, it has been an extremely profitable and expanding business" (*Anglo-Ind. Review*, April 1903). The returns for 1905-6 show, however, that in the severe fluctuations to which the traffic is ever subject, the pendulum has once more begun to swing forward. The ex-

Want of
Capital.

Improvement
in Trade.

ports recorded manifest a great improvement in tanned hides, amounting to an increase of 63·7 per cent. in quantity and 87·6 per cent. in value on the figures for 1904-5. The actual value of the hides exported in 1905-6 amounted to Rs. 1,54,80,070, and of the skins to Rs. 2,11,04,250, giving a total of Rs. 3,65,84,320; and in 1906-7, hides Rs. 1,72,96,337, and skins Rs. 2,72,16,204, or Rs. 4,45,12,541.

Leather.

LEATHER AND LEATHER MANUFACTURES.—Internal Industries.

—Although the objection to taking life is held very strongly by Buddhists and to a less extent by Hindus, it has not seriously opposed the growth of a trade in leather and leather manufactures. From the most ancient times in India, furs, skins, and leather have been used, and apparently to much greater extent than is the case to-day. Speaking of the frontier of India, Stein (*Ancient Khotan*, 1907, 345 *et seq.*) describes in great detail the ancient records, correspondence, etc., written on leather and wood, which he discovered during the exploration of the Niya site, and some of which bear the date of the 3rd century A.D. "The finish given," he says, "to the leather of these ancient documents indicates extensive practice in the preparation of the material." Leather, when once prepared, was thus not objected to by the early Buddhists of Khotan, any more than are the leather straps of the sacred books used by the orthodox Brahmins of to-day, in Kashmir and India generally. Book-binding in leather Stein regards as dating back to the Hindu period of Kashmir, and thus long anterior to the Muhammadan conquest. Many of the stucco statuary and fresco paintings of Ancient Khotan show personages riding on horses and camels, the saddles and trappings of which differ but little from those in use to-day; and the riders are often depicted wearing high boots of black leather richly embroidered in gold and silk. These circumstances may thus be accepted as indicative of an ancient knowledge in leather.

Ancient
Knowledge.

Horse
Trappings.

It is not contemplated to deal here in detail with the contrivances and materials of leather manufacture. The various provincial Governments of India have recently had prepared a series of publications entitled *Monographs on the Tanning and Working in Leather*. These, so far as they go, are admirable publications, and will be found to afford much useful information regarding the manufacture and utilisation of leather in India.

Leather.

Leather.—It may very truly be said that no large industry has changed more rapidly and completely than that of leather. Every axiom of the craft and even the reputation of leather itself has changed completely, for artificial leather is now a regular commodity. But speaking figuratively, India may be said to be many years behind the times. From being an industry in which time and capital had to be locked up almost indefinitely, tanning may now be spoken of as characterised by a rapidity of production and a turnover hardly equalled by any other branch of manufacturing enterprise. From being essentially a craft for manual labour, every stage in the tanning of leather and the preparation from it of the most artistically finished boots and shoes are accomplished by complex and intricate machinery. And what is even more significant, the countries that have responded most energetically to the discoveries of science and of mechanical skill have usurped or are usurping the leather trade of the world. Instead of it being now found necessary to retain hides and skins for a protracted period, subject to the slow action of some vegetable tanning material, rapid chemical methods (by mineral salts,

India behind
the Times.

Complete
Revolution.

Advance of
Science.

or even aided by electricity) have been called into existence and accepted with avidity by the trade. Electricity.

Chrome Process.—By the chrome process, for example, superior leather may be produced from the strongest buffalo hides in seven days, from cowhide in twenty-four hours, and from sheep and goat skins in six to eight hours; and these operations formerly took thirty days, or as much even as eighteen months. There are two methods of chrome tanning, viz. by one or by two vats. After the required submersion the hides or skins are removed from the drums and piled up on a table for twenty-four hours, so as to allow the tanning liquors to drain off slowly, the while completing the tanning process. After this the felts are well washed in several changes of water and are then put into a solution of borax and water to neutralise any trace of acid. The neutralisation of the acid is a point that demands careful consideration. After further washing the leather is now ready to be dyed or fat liquored, according to the purpose for which intended. Acid. Neutralisation.

A point of great moment is the circumstance that once dried, chrome leather can never again be sufficiently wetted to allow of treatment, so that the complete preparation for its final purpose must be undertaken almost immediately the hides or skins are taken from the vats. The half process pursued by many Madras tanners it would seem may have to be abandoned if they propose in the future to adopt chrome tanning. But the new process is neither expensive nor difficult, and with such improvements accomplished it is not difficult to understand why salted hides and skins are preferred to the more expensive half-tanned goods of Indian former trade. While the discoveries here briefly indicated and others too numerous to mention have proved of supreme moment to the leather trade of the rest of the world, the Native tanners of India have stood still and seen their interests being frittered away. Protracted immersion has for many years past been admitted as impossible in India. The superiority of European leather over that of India was accordingly freely acknowledged as a direct consequence of that circumstance. But now that scientific and effectual rapid methods have been designed and freely accepted in other countries, India alone stands aloof and speculates as to the obligation of Government to aid a decaying industry. With the few European manufacturers alone have the discoveries of the past twenty years assumed the position of guiding and controlling influences in internal reform and commercial advancement. Peculiarity of Chrome Leather. Preference for Salted Hides and Skins. Advantages of New Process.

Imports of Leather.—But in spite of general backwardness the leather produced by some of the tanneries, especially those under European management, is in certain respects fully equal to the best imported article, and for rough wear the boots turned out by the Cawnpore factories are even superior (especially when the price is taken into consideration) to the corresponding imported goods. This view would seem to be supported by the fact that the imports of unwrought leather do not appear to be advancing at a rate commensurate with those of manufactured leathern goods. Thus the imports in 1900-1 stood at Rs. 5,55,911; in 1901-2 at Rs. 4,18,348; in 1902-3 at Rs. 6,61,480; in 1903-4 at Rs. 3,81,192; in 1904-5 at Rs. 3,72,167; in 1905-6 at Rs. 4,24,596; and in 1906-7, Rs. 5,04,407. If to these figures be added the value of the imports of saddlery and other goods (except boots and shoes), the grand totals became in 1903-4, Rs. 26,19,633; in 1905-6, Rs. 30,60,820; and in 1906-7, Rs. 32,58,681. Imports. Unwrought Leather. Leathern Goods.

Tanneries.

Indian Tanneries.—Turning now to the statistics of tanneries in India, it may be said that in 1893 there were 44 tanneries that gave employment to 3,804 persons. Steadily these would appear to have increased until in 1902–3 it was ascertained that there were 202 tanneries and 6,200 employees. Of these tanneries, however, 183 were small concerns located in the Madras Presidency and concerned chiefly in the dressing of skins. In 1903–4 and subsequent years all the smaller works (those that gave employment to less than 25 persons) were excluded from consideration, and 43 tanneries were returned giving employment to 7,907 persons. In 1904–5 35 were returned, employing 5,981 persons. Of these 32 were in Madras (excluding the small skin-curing works). The tanneries of North India are six in number located in Cawnpore; four in Calcutta; three in Bombay; and one in Rajputana. The Cawnpore tanneries are by far the most important in all India. They produce superior leather, which is conveyed across the country and worked up by the local boot and shoe makers, saddlers, etc. The Cawnpore factories also turn out very superior boots and shoes, leather trunks, saddlery, etc., for which a large and growing market exists.

Dressed
Skins.

Cawnpore.

Local
Tanning.

Indigenous Methods.—But here and there, in every town and village of India, skins may be seen tanned by certain classes of people. It is no uncommon sight to find the skins of animals filled with tanning materials and left suspended from the boughs of trees or from the beams of the verandahs of the dwelling houses, until the desired change has been accomplished in the skin. In other instances crude vats, each containing one or two skins, may be discovered near the leather workers' houses. The provincial monographs will be found to contain highly instructive photographs, not only of such vats, but also descriptive details of many of the methods and contrivances of leather-curing practised in India. The tanned skins and hides produced in India by the indigenous tanneries are traded in all over the country and used up by the village workers. But the distinctly inferior nature of the leather so used may be illustrated by the fact that the articles produced rarely fetch much more than one-fourth the values of the corresponding articles made of imported or Cawnpore (European factory) leather. So again, Indian leather, owing to its low textile strength, is unsuited for belting purposes or any necessity where strength is essential.

Effete Methods.

Tanning
Materials.

Tanning Materials.—India possesses an extensive series of very excellent tanning materials such as ACACIA pods and bark (see pp. 6–7); CUTCH (see pp. 9–13); INDIAN SUMACH (see p. 913); the TANNER'S CASSIA (see pp. 289–90); the MANGROVES (see pp. 98, 293); MYROBALANS (see pp. 1073–6); and many others. By these and such-like materials and by various methods and contrivances, hides and skins are extensively cured, tanned and curried and the leather worked up, in response to an immense though purely local demand. [*Cf. Agri. Ledg.*, 1896, No. 9; Hooper, *Rept. on Tanning Extracts*, pub. by Inspector-General of Forests, Feb. 1898; *Tanning-Producing Substances*, Assist. Agri. Chemist to Govt. of India, 1901; Hooper, *Ind. Tanning Materials*, in *Agri. Ledg.*, 1902, No. 1, also numerous analyses in the Annual Reports of the Indian Museum (Economic) Laboratory.]

Concluding Observations.—In technical works it is said there are three chief methods of tanning:—(1) with infusion of bark or other vegetable materials; (2) with mineral salts; (3) with tanning oils. After

being tanned the skins are subjected to further treatment and are finally spoken of as "dressed."

Hides are tanned principally for sole, belting and harness leather; calf-skins for uppers of boots (light leather) and bookbinding; sheepskins afford a variety of leathers; goat skins are glove skins, although lamb skins and deer skins afford good substitutes in glove-making. The thickest sole leathers are made from the cattle of the less cultivated countries, since artificial protection seems to tend to render the skin thinner. The cattle of the River Plate are the chief source of the heavy hides or *butts*. Castration gives a more uniform hide, and these are much preferred. Hides of diseased animals are nearly always inferior, and moreover dangerous, as there would seem reason for believing that anthrax may be conveyed by imperfectly cured hides. Similarly the sheep most prized and most carefully produced as fleece-yielders afford very inferior skins. Hides may be preserved by being salted on the fleshy side or by being simply passed through a solution of arsenic and dried in the shade. This is the modern practice in India, especially at the yards of the large and important shippers.

Various
Qualities.

Anthrax

BOOT AND SHOE TRADE.—The imports of boots and shoes have for some years been increasing rapidly. In 1886-7 the supply was valued at Rs. 11,31,258; in 1903-4 at Rs. 27,93,249; in 1905-6 at Rs. 34,45,418; and 1906-7, Rs. 29,08,093. One of the most significant features of this trade is the expansion of American supply, which even in India has begun to be felt. The Indian market is thus one of growing importance, and this circumstance manifests the possibilities of the local industry, already well organised. Every village and town has its shoemakers. In the cities whole streets are often devoted to them, and one of the most surprising features of the trade is the very large number of Chinamen engaged in it. Native shoes are often elaborately embroidered and even jewelled. The places most famed for artistic shoes and leather work generally are in BENGAL—Cuttack, Patna and Saran. In the UNITED PROVINCES—Rampur, Lucknow, Agra, Jhansi and Saharanpur. In the PANJAB—Kohat, Rawalpindi, Peshawar, Dera Ghazi Khan and Hoshiarpur. In the CENTRAL PROVINCES—Chanda. In RAJPUTANA—Jaipur and Bikanir. In BOMBAY—Surat, Ahmedabad, Poona, Ratnagiri and Hyderabad (Sind). In SOUTH INDIA—Raichur, Salem, Trichinopoly, Madras and Mysore. These are the chief centres in the Native trade, but, as already said, Cawnpore stands out pre-eminently as the commercial centre of the modern trade (European style) in boots, shoes, saddlery, trunks, etc. Lastly, it may be added that for the past ten years or so India has begun to export boots and shoes. In 1898-9 this traffic was valued at Rs. 3,52,027; in 1902-3 at Rs. 10,59,052; in 1905-6 at Rs. 4,88,640; and in 1906-7, Rs. 4,68,491. These exports go from Calcutta and Bombay and are consigned mainly to Natal, Cape Colony, Mauritius and Egypt, with smaller quantities to England, Russia, etc. Indian (or, to be more correct, Cawnpore) ammunition boots are now well known in trade.

Exports.

Artistic Manufactures.—Belts, powder-flasks, saddlery, saddle-cloths, etc., etc., are extensively produced all over the country, and in some cases the goods turned out are of superior quality and highly artistic. The "Frontier Belts" of Peshawar, Bannu, Kohat and Quetta are well known and in much demand over a large portion of India. *Sambar* leather is also richly embroidered, and in the form of sheets, table-cloths, etc., is extensively used. The localities best known for the production of these are Gorakhpur in Oudh and Chanda in the Central Provinces. In the Karnul district of Madras leather mats are quaintly painted, and in many parts of Rajputana and Bombay leather is admirably stamped and engraved in bookbinding. The most noted centres for this art are Alwar and Ahmedabad. In Gujarat an industry has long existed in carving rhinoceros-hide shields. In some cases, instead of being carved the hide is so cured as to become almost transparent and of a pale amber colour. [*Cf. Ind. Art at Delhi*, 1903, 199-205; Hoey, *Monog. Trade and Manuf. N. Ind.*, 1880, 90-5; Blount and Bloxam, *Chem. for Engin. and Manuf.*, 1900, 367-95; Perkin, *Yellow Colouring Matter in Tan. Mat.*, *Chem. Soc.*, 1900, 423-32; *Monographs*:—Grant, *Leather Indust. Kurchi or Conessi Bark, *kara, kurra, kuda, karchi, kiuar, kogar, kachri, dhowda, dovla, vepali, pala, lettok kyi*, etc., etc. A small deciduous tree, found throughout India and Burma, ascending the lower Himalaya to 3,500 feet, and to a similar altitude on the hills of South India. It is an associate of *sál* (*Shorea robusta*) in Northern and Central India, and of *eng* (*Dipterocarpus tuberculatus*) in Burma.

Medicine.

Both bark and seed of this plant are among the most important MEDICINES of the Hindu *Materia Medica*. Garcia de Orta, who wrote in 1563 (*Coll.*, xxviii.; reprinted, in Clusius, *Hist. Exot. Pl.*, 1605, 227-8; also in Ball, *Proc. Roy. Ir. Acad.* (ser. 3), i., 412), speaks of this as being called by the Portuguese *herba Malabarica* owing to its great merit in the treatment of dysentery having been made known through the people of Malabar. In *The Bower Manuscript* (Hoernle, transl.) repeated mention is made of the drug (*kutaja* or *vatsaka*, the bark, and *kalinga*, the seeds), as also of *Picrorhiza Kurroa* (*kutika, rohini, katukarahini*, etc.), both of which seem to be regarded as having very similar properties. The preparation, generally in the form of a solid or liquid extract or of a decoction, is astringent, anti-dysenteric and anthelmintic. The bark of an allied plant, *Wrightia tinctoria* (see pp. 1131-2), has been confused with and substituted for the true *kurchi*, and thus led to the latter having fallen somewhat into disrepute. The bark of *Wrightia* may be distinguished from true conessi bark by its darker colour and by its not exfoliating in patches. The seeds yield a fixed OIL, and among the Santals the wood ash is used in dyeing. The Wood is largely used for carving, especially in Saharanpur and Bijnor districts; in Assam for furniture; in South India for turnery. [Cf. Buchanan-Hamilton, *Stat. Acc. Plants*, 1903, ii., 1231; **GRAMINEÆ**. Barley, *jav, súj, nas, tosa, yurk, thanzatt, satú, barli-aris, yava*, etc.

Habitat.—An annual grass producing many stems from a single grain, and becoming 2 to 3 feet long. It occurs throughout the temperate and extra-tropical regions of the globe, and in India is met with from the plains to altitudes of 14,000 feet above the sea-level.

Varieties.

There are several well-marked varieties, of which the most important are:—*var. (a) hexastichon*, Aitchs.; *var. (β) distichon*, Linn.; and *var. (γ) nudum*, Ard. *Hexastichon*, or six-rowed barley, is that which is

VERY ANCIENT CEREAL

HO D UM
VULGA
Cultivation

most commonly cultivated in India. The only variety hitherto found wild is *distichon*, which seems to be indigenous to Western Temperate Asia.

istory.—Barley is amongst the most ancient of cultivated plants, but as its forms resemble each other very closely in their properties and seem to have had, in all languages, common names, it is not easy to ascertain which variety is referred to by the early writers. Proofs in abundance exist that one or other of the forms has been cultivated since the remotest times. According to Bretschneider, barley is one of the five cereals sown by the Emperor Shen-nung of China, who reigned about 2700 B.C. Theophrastus was acquainted with several forms of barley, and it was an important article of food in the time of Solomon (B.C. 1015). The variety *hexastichon* has been found in the earliest Egyptian monuments, as also in the remains of the later dwellings of Switzerland and of Savoy. The six-rowed barley is represented on the medals of Metapontes—a town in South Italy—of date 6th century B.C. The oldest known Indian (or rather Central Asiatic) samples of barley are those collected by Stein at Karadong (*Ancient Khotan*, 1907, 448). The ruins in question had been engulfed by sand about the close of the 8th century A.D. The variety most frequently met with in India is also *hexastichon*. Indra is called “the god who ripens barley,” and as still manifesting ancient knowledge it may be added that the grain is employed in the ceremonies attending the birth, marriage and death, as also certain sacrificial rites. This idea is also borne out by the antiquity of the Sanskrit name *yava* (*yavaka*), which in the earliest times was a general term for corn or grain, but which with time became restricted to what must have been at least a very important grain—barley; hence have come the modern vernaculars—*jau*, *Indrajau*, *jawa*, etc. The grain is also closely associated with the Indian Muhammadans. In the *Ain-i-Akbari* the crop is said to have been one of the most important in Afghanistan and Kashmir, a large part of the revenue in these countries having been obtained from barley by exacting the usual two out of every ten *kherwars* produced.

CULTIVATION.—Barley is a *rabi* crop, sown in October or November, and reaped in March or April. In Bombay it is generally grown alone, occasionally with a sprinkling of rape or mustard, but in many parts it is often mixed with wheat, gram, peas or lentils, while rape, Indian mustard and linseed are commonly sown as borderings. The soils on which it thrives best are light and sandy, and, as a rule, not highly manured. The number of PLOUGHINGS before sowing varies, but four would be a fair average. The SEED-RATE runs from about 80 to 120 lb. per acre. It is sown by plough-furrows, the surface of the ground being subsequently levelled and beds for irrigation formed. IRRIGATION, however, may not be necessary, and in districts which enjoy a tolerable certainty of rain it is but rarely resorted to. Little WEEDING is required, the crop being left very much to itself till March–April, when it is REAPED like wheat, tied up in sheaves, and stacked near the homesteads to dry. The preparation for the market is the same as that for wheat. The total cost of growing an acre is variously stated: Mukerji puts it at only Rs. 18–8; Duthie and Fuller, Rs. 20–12; and Mollison gives for Gujarat, Rs. 51–8–0. Huskless barley from Saharanpur is described in the *Kew Bulletin* (1888, 271–3).

Areas under the Crop.—From the *Agricultural Statistics of British India*, it appears that in recent years far the largest quantity of this cereal is grown in the United Provinces and in Bengal. The Panjáb, North-West Frontier, Ajmer-Merwara, Bombay, the Central Provinces, Sind and Madras follow in the order given. The total area under barley in British India for the year 1905–6 was 7,326,755 acres. Similarly, in the Native States, the area in the same year is said to have been 418,463 acres, chiefly in Jaipur, Alwar, Bharatpur and Gwalior.

Bengal.—The cultivation of barley is mostly restricted to the central Bengal.

THE BARLEY PLANT

and northern districts. It is more especially met with in South Bihar, where it forms one of the cheapest of foods. In North Bihar (Bhagalpur) it is of less importance. The cultivation of barley diminishes south and east, and is practically not grown in Bengal proper nor in Orissa. Though in recent years Bengal stands second as regards the total area under this crop, within the province it is comparatively unimportant, the percentage of the normal area under barley having amounted in 1904-5 to only 2.50. The total barley area in that year was 1,514,700 acres, and the yield 494,243 tons; hence if an average be assumed, these figures would show 6.4 cwt. per acre. In 1906-7 the area was 1,411,100 acres. The chief localities are usually Patna, Bhagalpur, and Chota Nagpur. [*Cf. Mukerji, Handbook Ind. Agri.*, 1901, 245-7; Basu, *Agri. Lohardaga*, 1890, ii., 32-3; Banerji, *Agri. Cuttack*, 1893, 78-9; *Rept. Admin. Beng.*, 1903, 15; *Ind. Planters' Gaz.*, Sept. 19, 1903; Oct. 10, 1903.]

U. Prov.

United Provinces.—These provinces stand first in British India as regards the total area under barley and the annual output. In 1905-6 it amounted to 4,127,936 acres, of which Agra contributed 3,137,104 and Oudh 990,832. The largest areas were in the Gorakhpur, Benares, Lucknow and Allahabad Divisions. Duthie and Fuller estimated the average outturn of unmixed barley at 16 maunds per acre if irrigated, 8 to 11 maunds if unirrigated. [*Cf. Cawnpore Exper. Farm Rept. Dist. Gaz., U. Prov.* (many passages).]

C. Prov. and Berar.

Central Provinces and Berar.—The total area for 1905-6 in these provinces would appear to have been 11,608 acres, and the chief districts Jabbalpur, Damoh, Bilaspur and Chanda. Of Berar, 94 acres have been returned as under this crop.

Rajputana.

Rajputana.—The crop is apparently an important one, especially in Ajmer-Merwara, where, during the ten years ending 1899-1900, it is returned as having occupied 16.1 per cent. of the average cultivated area. [*Cf. Rajputana Gaz., Ajmer-Merwara*, 1904, i., 46.] But of the whole province, in 1904-5, mention is made of a total area of 38,728 acres. In irrigated land it yields an average of about 7.34 cwt. per acre, but in dry crop land the average outturn is given as only 1.46 cwt.

Panjáb and N.-W. Frontier.

Panjáb and North-West Frontier.—The system of cultivation is very similar to that in Bombay and the United Provinces, but the practice of topping an over-leafy crop is said to be common; the crop is generally grown unmixed. The total area for 1905-6 was 1,205,678 acres in the Panjáb and 315,272 acres in the North-West Frontier. The most important localities are usually Ferozpur, Hissar, Gurgáon in the Panjáb; Peshawar, Hazara and Bannu in the North-West Frontier. [*Cf. Montgomery, Barley Cult. Pb.*, in *Select. Rec. Finance Comm. Office*, 1885, No. 29; *Rept. Govt. Agri.-Hort. Gard. Lahore*; *Dist. Gaz. Pb.* (many passages).]

Kash ir.

Kashmir.—According to Lawrence (*Valley of Kashmir*, 1895, 341), barley is the most important spring crop, if area alone be considered. It is not, however, of good quality, and no pains are taken in its cultivation. In the higher villages, at an elevation of 7,000 feet, there is a peculiar variety known as *grim*, or Tibet barley. The grain is naked like wheat, and it is said that if cultivated at a lower level it takes on the type of ordinary barley. It is sown in May and June, ripens in August and September. Barley gives on an average 8½ maunds per acre; *grim*, about 4 maunds. [*Cf. Assess. Repts. Baltistan* :—Kaye, *Skardu Tahsil*, 1901, 8-9; Clarke, *Kargil Tahsil*, 1901, 19, 23; also *Skardu Tahsil*, 1901, 20-3.]

MILLING AND MALTING

O D U
VULGA
Cultivation
Bombay.

Bombay.—Barley is not extensively grown in Bombay. In 1905-6 the total area was only 23,103 acres. In that year Ahmedabad grew 11,330 acres; Kaira 3,448; Satara 4,807; Sholapur 1,284; and Panch Mahals 463. It is generally grown alone, occasionally with a sprinkling of rape or mustard. In parts of Gujarat wheat and barley are grown mixed. As in other provinces, it is a light-soil crop, the sandy loams of Kaira and Ahmedabad district being particularly suitable. Mollison remarks that 1,500 to 1,800 lb. of grain per acre and about a ton of straw are considered a full average yield. [*Cf.* Mollison, *Handbook Ind. Agri.*, 1901, 44-9.]

Madras.—Barley is a very unimportant crop. For the year 1905-6 the total area in the Presidency amounted to only 3,280 acres, all in the Nilgiris. In Mysore the total in 1905-6 was 1,338 acres.

Milling or Preparing.—The process of cleaning barley for food purposes is generally carried out by pounding in wooden mortars and winnowing, or by beating with a flat board. The grain is then ground into coarse meal from which alone, or mixed with the meal of wheat or gram, *chapattis* are made and baked; or a gruel or pasty mass is made, to which salt is added and the preparation eaten with garlic, onions or chillies. In either of these forms it is a staple article of food among the poorer classes. The grain, thus roughly cleaned and ground, is richer in albuminoids than the more carefully prepared culinary barley of Europe; but at the same time it is more difficult to digest, and is thus partly unsuited for the dietary of dyspeptics or invalids.

In various parts of India barley is now largely employed in the preparation of beer or spirituous liquor, and the use of barley in Europe for malting and brewing is well known (see *alt Liquors*, p. 759; *Vine ar*, p. 1109). Mollison gives an account of the qualities which give barley a special value for these purposes. It is also largely used as a horse and cattle fodder. In some parts of India the crop is cut two or three times when quite young, without marked injury to the final yield of grain. The straw even of ripe barley makes a fairly good fodder when cut up as *bhúsa*, but is inferior to that of wheat. The grain is a good feed both for horses and cattle, either given alone or mixed with gram.

Properties and Uses.—The chemical composition of ordinary husked Indian barley is given by Church as follows:—in 100 parts: water 12·5, albuminoids 11·5, starch 70·0, fat 1·3, fibre 2·6, ash 2·1. The nutrient ratio is here 1: 6·3 and the nutrient value 84·5. In medicine, barley is demulcent and easily digested, and is much used in the dietary of the sick. Malt extract has become extremely popular both as a nutritive and demulcent, and as a means for rendering other medicines palatable.

Trade.—Official trade statistics show the following as the *EXPORTS* from British India in the six years ending March 31, 1907:—1901-2, 54,648 cwt., valued at Rs. 1,80,180; 1902-3, 63,872 cwt., valued at Rs. 2,27,937; 1903-4, 113,120 cwt., valued at Rs. 3,56,421; 1904-5, 376,548 cwt., valued at Rs. 12,68,154; 1905-6, 92,810 cwt., valued at Rs. 3,12,548; and 1906-7, 406,067 cwt., valued at Rs. 12,51,753. There was thus a steady increase till 1904-5, but a sudden decrease in 1905-6. In 1904-5 (the record year) Bombay exported the largest share, viz. 231,037 cwt. (though in the previous year it exported only 25,883 cwt.); Sind 86,070 cwt.; and Bengal 59,307. The relative shares of the exporting centres are, however, subject to great variation. During the same period the *IMPORTS* were:—1900-1,

iv., 4-9.
Horn and
orn-
work.

HORN , ANTL R , AND HORN-WORK.—Blanford, *Fa. Br. Ind.* (Mammalia) 1888-91 (respective pages of species below). HORNS and ANTLERS are largely utilised in the manufactures of the world, and in their crude state are fairly extensively exported from India. The traffic is mainly in the hands of the dealers in HIDES and SKINS.

The following animals will be found fully discussed under Live Stock (pp. 732-49), and, as they are the chief sources of the horns of Indian commerce, that article should be consulted:—*Bos indicus* (l.c. 483-93), the breeds of the Ox; *B. bubalus*, the wild and domesticated Buffalo; *B. grunniens*, the Yak; *B. frontalis*, the gaval; *B. gaurus*, the Bison; and *B. sondaicus*, the Banting or Burmese Wild Bull. *Capra* (l.c. 501-8), the various breeds of Goat; *C. aegagrus*, the Baluchistan, etc., Wild Goat; *C. falconeri*, the Markhor; *C. sibirica*, the Ibex. *Ovis* (l.c. 493-501), domestic Sheep; *O. hodgsoni*, the Tibetan Great Sheep; *O. nahuia*, the *bharul*; *O. poti*, the Great Sheep of the Pamirs; and *O. vignei*, the *kuch* or Wild Sheep of the Salt Range. Lastly, a small group of transitional animals such as *Hemitragus jemlaicus* (l.c. 508-12), the *tehr* of the Western Himalaya; *H. hylocrius*, the Nilgiri Wild Goat. *Nemorhedus bubalinus* (l.c. 512-5), the Himalayan Goat-antelope; *N. sumatrensis*, the Burmese Goat-antelope. *Cemas goral* (l.c. 516-7), the *goral* of the N.W. Himalaya, or Himalayan Chamois. The *Boselaphus tragocamelus* (l.c. 518-9), or *nilgai* or Blue Bull. *Tetracerus quadricornis* (l.c. 519-21), the Four-horned Antelope. *Antelope cervicapra* (l.c. 521-4), the Black Buck. *Gazella bennetti* (l.c. 526-8), the Indian Gazelle, etc., etc. To that list of BOVIDÆ—Oxen, Sheep, Goats and Antelopes—has to be added the Deer, such as *Cervulus muntjac* (l.c. 532-4), the Barking Deer. *Cervus axis* (l.c. 534-51), the Spotted Deer; *C. cashmirianus*, the Kashmir Stag; *C. duvauceli*, the *barasingha*; *C. eldi*, the Manipur Deer or *thameng* of Burma; *C. porcinus*, the Hog-deer; *C. unicolor*, the Sambar or Rusa Deer. And *Rhinoceros unicornis* (l.c. 472-4), the great One-horned Rhinoceros, etc., etc. Such then may be given as an enumeration of animals from which, in India and its mountainous frontiers, horns and antlers are obtained. Commercially, however, the horns might almost be said to be derived from the domesticated oxen—all the others being special or fancy articles, in which there is but a limited traffic.

Classification.—Horns may be grouped as follows:—

I. Those that consist of bone and which possess no true horny matter in their structure.

(a) True bone, such as antlers of deer.

(b) Epiphyses or separate pieces of bone covered by skin, such as in the horns of the giraffe.

II. Horns that more or less consist of true horny matter.

(c) Bone tipped by horn, such as in the horns of the prong-horned antelope.

(d) Bone covered or sheathed by true horn, such as in the ox.

(e) True horn throughout, such as the nasal horn of the rhinoceros.

True horny matter is formed by a modification of the epidermal tissue (the superficial layers of skin) and consists of an albuminoid material called *keratin*, a substance identical with the chief constituent of wool.

Horns of the *first* group are largely exported from India to England, under the name of deer-horn. The antlers chiefly traded in are those of the spotted deer (30 inches and under) and the *sámbár* (40 inches and under). They are extensively employed in Europe as bone handles for cutlery, umbrellas, sticks, etc. The *second* group are valued on account of the special properties of *keratin*; it is elastic, flexible and tough, and readily softens under heat and allows of the substance being moulded and welded as desired. Long, straight buffalo-horn is valued as a substitute for whalebone, and on this account fetches a higher price than curved horn. Accordingly, the tips are cut off and sold separately. The horns of sheep and goats are whiter and more transparent than those of other animals, and are, therefore, most valued for comb-making, while certain buffalo-horns are in demand for ornamental work. Perhaps one-fifth of the horns imported into England are used up in the comb trade, a small proportion being utilised for fancy work, such as shoe-horns, scoops, drinking-cups and the like. The solid tips, as also the hoofs of cattle (which consist largely of *keratin*), are made into buttons. The long, straight horns are cut into strips softened in a solution of bi-carbonate of soda; the strips being allowed to sweat, are then bevelled and pressed together, when they unite into the strips that are employed in place of whalebone. In Jaipur and elsewhere in India long straight horns have similarly been used from ancient times in the manufacture of bows and arrows.

Exports.

From Bombay.

To United
Kingdom.

Trade in Horns and Horn eal.—The *EXPORTS* of horn of all kinds from India were 71,894 cwt., valued at Rs. 12,80,051, in 1876-7; a decade later the quantity had been reduced by nearly one half, but the value remained the same; a decade still later the exports were 59,804 cwt., valued at Rs. 16,73,241. The traffic is one that fluctuates extremely according to climatic conditions. In times of scarcity and famine the exports increase and the horns decline in value, while in times of plenty the quantity decreases and the value increases. During 1901-2 the exports were 62,944 cwt. and Rs. 13,35,759; in 1902-3, 71,396 cwt. and Rs. 17,05,257; in 1903-4, 48,405 cwt. and Rs. 12,05,798; 1904-5, 61,582 cwt. and Rs. 13,72,375; 1905-6, 73,521 cwt. and Rs. 17,49,944; and in 1906-7, 78,771 cwt. and Rs. 16,91,532. Usually about 50 per cent. of the trade goes from Bombay, and approximately a similar proportion of the total is consigned to the United Kingdom—the shares taken in 1899-1900 having been 45,660 cwt.; in 1903-4, 25,718 cwt.; and in 1906-7, 26,678 cwt. France is the next most important receiving country, having taken in 1899-1900, 25,590 cwt.; in 1903-4, 13,226 cwt.; and in 1906-7, 32,887 cwt. The share contributed by Calcutta is ordinarily little over half that of Bombay. The *IMPORTS* drawn by India from foreign

Internal
Trans-
actions.

countries (by sea) are unimportant, in 1903-4 having been only 353 cwt., valued at Rs. 75,041; and in 1905-6, 316 cwt., valued at Rs. 69,318.

The examination of the returns of trade carried by rail and river reveals the fact that the chief provinces of supply are Bombay, the United Provinces, Central Provinces, the Panjáb, Bengal and Madras. Official returns of the trade of England and Continental countries distinguish as a rule the traffic in deer horns from that in buffalo, and judged from these it would appear that India is one of the chief countries from which the former are obtained. Indian trade statistics do not separate the two, so that the returns reviewed above are for all grades collectively.

Industries.

Indian Industries.—The chief forms of horn used in the Indian craft (*kangi-sáz*) are buffalo and bison horn, since there are religious objections to the use of cow-horn. A cup made of rhinoceros-horn is much prized by Hindus, but it is too scarce a material to be generally used. Buffalo-horn is by far the most largely employed in India of all horns, but it is the least beautiful. It is made into cups, tumblers, combs, musical instruments, work-boxes, powder-flasks, bows and arrows, *hukka* mouth-pieces, scent-bottles, snuff-boxes, sword, dagger and knife handles, and many other such articles. The centres of the trade are Cuttack, Monghyr, Satkhira (Khulna), Hughli and Serampore in Bengal, where combs, brooches, necklaces, snake bangles and the like are made. Rajputana, Jaipur and Kota are famed for their horn works. Rajkote combs, Baroda spoons, Kathiawar knife-handles, Surat and Ahmedabad veneered boxes and Baroda animal toys of horn are all well known. In Mysore, umbrella-handles, powder-boxes and buttons are made of buffalo-horn, and often richly inlaid with ivory and copper. But it is in Vizagapatam that horn veneered work may be said to have assumed the condition of high-class ware. In Ratnagiri and Savantvadi a fair trade is done in bison-horn work. Aitken (*Agri. Ledg.*, 1897, No. 10) wrote a most interesting account of the industry in the former locality. Perhaps the most instructive feature of that publication may be said to be the method of softening the horn. It is coated with cocoanut-oil and heated before a fire until it becomes sufficiently soft to allow of its being pulled out and moulded into the desired shape.

The Asiatic Penny-wort, *brahmi*, *brāhmamanduki*, *tholkuri*, *karivana*, *vallārai*, *mandukaparni*. A small herbaceous plant, found throughout India from the Himalaya to Ceylon at altitudes up to 2,000 feet.

Medicine.

The medicinal properties of this plant were known to Sanskrit writers of very remote times, and the early European writers on Indian *Materia Medica* were also acquainted with the plant. The parts generally employed are the leaves, dried by exposure to the air and ground to a powder. The powder is of a pale green colour and exhales a slight characteristic aroma. It is an alterative, tonic and a local stimulant, said to be efficacious both as an internal and external remedy in ulcerations, eczema, leprosy and other cutaneous affections. The chemistry of the leaves was first investigated by Lepine in 1855, who found they contained oily and resinous constituents, with mucilaginous principles and

tannin, to which collectively he gave the name of *vellarin*, a word derived from the Tamil name of the plant. [Cf. Christy, *New. Comm. Pl.*, 1878-88, 58-62; *Pharmacog. Ind.*, ii., 107-10; Waring, *Baz. Med. of Ind.*, 1897, 75-6; *Pharm. Journ.*, July 1, 1899, lxiii., 16-7; Dutt, *Mat. Med. Hind.*, 1900, 176; *Rept. Cent. Indig. IN IA- U R, CAOUTCHOUC OR GUM LA TIC.

—Caoutchouc, like gutta-percha, is a vegetable inspissated milk or latex. In both cases the substance consists of a hydrocarbon, forming corpuscle-like bodies floating in a fluid. Gutta-percha becomes soft and plastic in hot water and may be moulded into any desired shape, which it preserves on cooling. Caoutchouc, on the other hand, is not softened by heat, is impervious to water, alcohol and most acids, etc., and retains its elasticity for a considerable period. Gutta-percha is chiefly obtained from trees that belong to the SAPOTACEÆ, while caoutchouc is derived from certain plants which have been placed in three widely different natural orders. These are *Funtumia*, *Hancornia*, *Landolphia* and *Willoughbeia* of APOCYNACEÆ; *Castilloa* and *Ficus* of URTICACEÆ, and *Hevea* and *Manihot* of EUPHORBIACEÆ. The plants that afford gutta-percha and india-rubber thus manifest no definite botanical affinity, except that they are mostly natives of tropical countries. In the plant tissue caoutchouc circulates within certain anastomosing vessels which are distributed throughout the middle, or more rarely the inner layer of bark. [Cf. Lecomte, *Journ. d'Agri. Trop.*, 1903, xvii., 375.] A far larger number of plants possess milk (and even a caoutchouc-yielding latex) than those generally viewed as the sources of india-rubber. The term caoutchouc is sometimes used synonymously for india-rubber, but it more correctly denotes the pure hydrocarbon isolated from the other materials with which it forms the impure rubber of commerce. Caoutchouc is highly elastic, lighter than water, has neither taste nor smell, is fusible at about 248° F. and inflammable at higher temperatures.

Methods of Agglutination.—When the bark of plants containing rubber is cut, the milk exudes, and in time hardens on exposure to the air. This agglutination may be hastened by adding salt water, alum or acetic acid to the milk; but these, more especially salt, increase one of its defects, viz. the hygroscopic property by which it becomes moist and sticky, and in consequence they injure it commercially. A favourite but wasteful method is to allow the milk to flow into holes in the ground and to be left there till the water, etc., has drained off. Boiling the milk is the system followed in Lagos, while in the Amazon valley the smoke of a smouldering fire, combined with moderate heat, is the system almost universally pursued with Para rubber. In a few cases the milk is simply allowed to dry as it trickles down the stem. This gives the SCRAP RUBBER of Ceara and a good deal of that of Assam and Penang. The alum (or Penang) process was recognised as being useful for Assam, where the humid atmosphere operates against the drying of the rubber. Dr. C. O. Weber, in a series of articles contributed to *The India-rubber and Gutta-percha Trades Journal* in 1902, also 1904, has stated the facts regarding coagulation briefly as follows:—

1. That the so-called coagulation of rubber by acids or alkalis is

Boiling.

Smoking.

Scrap Rubber.

Alum.

Weber's
Method.

erroneous in that it is only the albumen which is coagulated by these substances, and not the india-rubber itself.

Albumen.

2. That the albumen contained in latex is very harmful in many respects, and that it ought to be as far as possible eliminated from the milk before attempting to agglutinate the rubber.

3. The method he recommends for coagulation is briefly as follows :—First mix the latex with water, at least five times its volume. In cases where the latex is thick, actual boiling water may be used with advantage. In this state it can be easily strained to remove impurities. After this, add formaldehyde in the proportion of 8 oz. to a petroleum barrel ; stir well and let it stand for twenty-four hours, when the rubber will collect on the top and can be lifted out in one mass. In order to remove any traces of albumen that may be suspended, the rubber should next be cut into strips and subjected to a thorough washing upon an ordinary rubber washing-machine. [Cf. Weber, *Chem. India-Rubber*, 1902.]

To aldehyde.

Centrifugal separator.

But the use of formaldehyde does not seem to have been the success that Weber anticipated, though his recommendation for cleanliness and repeated washing has been universally accepted. Biffen (*Annals of Botany*, 1898, xii., 165–71) suggested the use of a centrifugal separator. The milk is mixed with 50 per cent. of water, and set revolving for a time. It is then found that the rubber floats on the top in a thick mass. The albuminoids, etc., and all the adulterants are found below. It has next to be admitted that by many recent writers the value of centrifugal force has been denied, and special machinery patented in which the merit claimed is that they do not involve centrifugal action.

Dry-bark Process.

Indian Planting and Gardening (March 29, 1900) published a letter from Faber that gives particulars of a method of extracting caoutchouc from dry bark, said to have been discovered by a French chemist, M. G. Deiss. This process consists in keeping slices of bark and roots soaked in dilute sulphuric acid while being heated. The woody portions become decomposed and can then be washed out, thus leaving the rubber in a pure state. For other methods of extracting india-rubber by solvents or mechanical processes the reader should consult Gerber's article on that subject. [Cf. *Journ. Soc. Chem. Indust.*, 1902, 414–5 ; *Kew Bull.*, 1898, 177–81 ; Mathieu, *Agri. Bull. Straits and Fed. Mal. States*, 1903, ii., 18–21 ; 1905, iv., 223–4.

Chemical position.

Co position of Rubber.—India-rubber may be said to consist chemically of two substances—an elastic material, on which its merit depends, and a viscid resinous substance readily oxidisable, to which it owes its depreciation. Hence the greater the percentage of resin the less the value of the sample. The property of the elastic substance also varies, and in a marked degree, between that obtained from one genus of plants and that of another, so that every gradation exists from the non-elastic hydrocarbon known as gutta-percha (which see, pp. 625–8) to the finest gum elastic. Caoutchouc yields by dry distillation a mixture of simpler hydrocarbons, called oil of caoutchouc or *caoutchoucine*, which forms an excellent solvent for caoutchouc and other resins.

Caoutchouc.
Resin.
Empyreumatic Oil.

Rubber.

History.—During the second voyage of Columbus it was noticed that the inhabitants of Hispaniola (Hayti) played with balls made from the gum of a tree. In 1770 Priestly recommended the use of that substance for the purpose of erasing pencil markings, hence the name “rubber.” The article was new to Europe, and the proposed utilisation of it excited some interest. It was not, however, until 1820 that the beginning of the modern industry can be traced.

Three years later Mackintosh created the waterproofing trade by dissolving rubber in naphtha. Nelson Goodyear in 1839 vulcanised it, and this rapidly led to the production of ebonite. Rubber and its products may now be spoken of as indispensable to the domestic life and to manufacturing and engineering enterprises of the entire human race. J. G. Baker wrote in 1886 (*Gard. Chron.*, xxv., 363) an interesting article on the production of this all-important substance. Part of the supply, he then wrote, comes from SOUTH AMERICA, shipped from Para and Carthagená, part from SIERRA LEONE, Mozambique and Madagascar, and the remainder from tropical Asia. After exhibiting the botanical and geographical supplies, Baker dealt with the future, and what he then urged regarding cultivation has proved the keynote to present successes. So in the same way Sir George King, while reporting the introduction of *Landolphia* into the Botanic Gardens of Calcutta, observed that the exotic rubbers "with the exception of *Ceara* are either very large trees or climbers: and although it may pay well to collect rubber from them in their native forests, where they have grown to maturity without cost to the collector, it is quite a different matter when their planting and protection have to be paid for, and their coming to maturity has to be awaited for years." That opinion has since been somewhat modified, though, so far as the interests of the European planters (who are at most temporary residents in the tropics) are concerned, not materially. The plantations established by the Government of India have, however, begun to prove of considerable value, as have also some of those made by private enterprise. Indeed, the experience of the past few years would seem to show that perhaps greater success may attend private enterprise in this direction than was currently believed a few years ago.

Waterproofing.
Ebonite.
Modern Phases.

Trees and Climbers.

Conditions of Success.—The whole question of rubber production seems to turn on the cultivation of quick-yielding species, on superior methods of causing and securing the flow of milk, and on the high prices prevailing for carefully prepared rubber. The production of caoutchouc by the spontaneous change of the hydrocarbon *isoprene* is not at present of practical importance. Many of the oxidised-oil products now being manufactured manifest not a few of the properties of rubber and seem destined to relieve the strain for supplies of the natural article, but they have all one serious defect, namely they possess no elasticity. Accordingly, the fear of over-production of natural rubber, most writers think, is at present infinitesimal. [*Cf. Ind. For.*, 1898, xxiv., 187; *Kew Bull.*, 1899, 27; *Journ. Soc. Chem. Indust.*, 1902, xxi., 56; 1904, xxiii., 556.]

success.
Conditions.

Isoprene.

Modern Demand.—The growth of modern demand for rubber may be manifested by the following: the exports from the Amazon valley alone in 1864 came to close on eight million pounds, and thirty years later (1904) they came to sixty-seven million pounds, a quantity that represents the systematic tapping of twenty million trees, and which fetched over thirteen million pounds sterling (see p. 660). In India, Ceylon and the Federated Malay States rubber cultivation is being vigorously prosecuted, and the future seems destined to see a still further expansion in these countries.

Demand.

Twenty Million Trees.

Asiatic Production.—In Ceylon during 1905 there are believed to have been 40,000 acres devoted to *Hevea* and to a lesser extent to *Castilloa* rubber trees. The plantations are mostly within the valleys, but some extend up to an altitude of 2,000 to 2,500 feet. It seems an accepted axiom that the higher *Hevea* is planted, the slower it will grow and the less the yield. *Castilloa* ceases to be profitable in Ceylon at altitudes above 1,500 feet. It has recently been urged, regarding Ceylon, that it might pay to extend plantations of these rubbers into tracts that have to be systematically irrigated. Speaking of South India, Mr. Proudlock, Curator of the Government Gardens on the Nilgiri hills, made an interesting discovery, viz. that *Castilloa* trees three or four years old, in the Barliar plantation (2,400 feet), yielded a somewhat

Ceylon.

Castilloa.

Season for
Tapping.

Travancore.

Com-
mercial
Rubbers.
Biscuit.

Scrap.

gummy substance destitute of the properties of true rubber. Fifteen months later these self-same trees yielded a better quality of rubber; hence he concludes that the change from yielding a gummy substance to yielding a true rubber coincides with, or closely follows the period when the species first begins to produce ripe seed. In Travancore much interest has been taken by His Highness's Government in the allocation of suitable tracts within the valleys of the State for rubber plantations.

Commercial Rubbers.—The rubbers of commerce are (a) the biscuit and bottle rubbers of South America, such as the Para (the most important) which comes from Brazil, Venezuela, and recently from Ceylon and the Straits. (b) Castilloa, such as the Central American rubbers, of which there are certain grades:—Nicaragua, West Indian, Honduras, Mexican, Guatemala, Panama and Peruvian. These appear in BLOCKS, SHEETS or SCRAPS. (c) The true Ceara is a dry rubber, very elastic, and free from stickiness; it coagulates in tears forming scrap. (d) Pernambuco and Mangabeira are coagulated with salt and are accordingly "wet" rubbers. (e) Numerous trade forms of African rubber, such as Gambia, Sierra Leone, Lagos, Gold Coast, Congo (ball), Calabar, Cameroon, Batanga, Liberian, etc. (f) Mozambique (ball), Sausage (liver), Madagascar (good and fine, also black). (g) Asiatic, such as Assam, Rangoon, mostly scrap rubbers formed into cakes, slabs or loaves. (h) Javan, Bornean, New Guinea, etc., rubbers (see *Gutta-percha*, p. 626).

[Cf. Thomas Bolas, *India-rubber and Gutta-percha Indust.* (six lectures), in *Journ. Soc. Arts*, 1880, 753-813; *India-rubber and Gutta-percha Indust.*, in *Ind. For.*, 1898, xxiv., 111-9; *Rubber*, in *Queensland Agri. Journ.*, 1899, v., 410, etc.; Morris, *Sources of Comm. Rubber*, *Cantor Lect. in Journ. Soc. Arts*, July 1898, 745-96; Sadebeck, *Die Kulturgew. der Deut. Kolon.*, 1899, 268-81; Wiesner, *Die Rohst. des Pflanzenr.*, 1900, i., 356-89; Semler, *Trop. Empire*, 1907; Hemsley, *Kew Bull.*, 1907, 153-6; *The Ceylon Rubber Exhibition*, in *Agri. Journ. Ind.*, 1907, ii., pt. i., 73-80.]

The following, in alphabetical sequence of their scientific names, may be given as a brief statement of the india-rubber yielding plants of the world in which India is presently interested:—

D. P.,
iv., 3 4-5.
Castilloa.

Castilloa elastica, *Cerv.*; Hemsley, *l.c.* 156; URTICACEÆ. Central American, Panama and Nicaragua Rubber. Torquemada was the first to mention the rubber of Mexico. He gave it the name of *ulé*. Long years after, Cross successfully introduced the plant to the Old World. In 1876 he conveyed live plants to Kew Gardens, and from that supply the plants that first reached Ceylon and finally India were distributed by Sir William Thiselton-Dyer. Willis and Wright (*Handbook Veg. Econ. Prod. Ceylon*, 1901, 41-5) give many useful particulars regarding the experience gained in that country. Mr. W. S. Todd subsequently was successful in having conveyed from Mexico and San Salvador seeds which he germinated in Burma and ultimately sent supplies to Samoa, a fact of some interest, since the seeds of this species are believed to lose their vitality very rapidly. But there are two species of *Castilloa* that yield rubber, and comparative studies have not as yet established which is the more preferable for special cultivation. The Indian and Ceylon plant is chiefly *C. elastica*, the Mexican species, and *C. Tunu*, that of British Honduras and Costa Rica. This is the *tunu* rubber or *el hule macho* (the mule-rubber), but is not the mule-rubber of Brazil.

Manson (*Ind. For.*, 1901, xxvii., 75-96) furnishes much useful information regarding the India-rubber plants of India. Of this species he remarks that it is cultivated in Mergui under wrong conditions, namely on swampy ground. He recommends that it should be tried in Tenasserim on hillsides with a western aspect. The plant has been fairly successfully grown on the hills of South India,

Indian
Experience.

Two Forms.

as, for example, near Calicut and Malabar, as also on the Nilgiri hills (Barliar). Speaking of experience gained in Bangalor, Cameron (*Rept. Govt. Bot. Gard.*, 1902-3, app. ii. and iii.) says this plant is intermediate between Para and Ceara, requiring neither the tropical humidity of the former nor the open and comparatively dry conditions of the latter. It is, in fact, a tree for the coffee zone. He accordingly recommends it for the moist regions of the hills, and Ceara for the plateau of Mysore. [*Cf. Morris, Cantor Lect. l.c.* 761-5; *Circ. Roy. Bot. Gard. Ceylon*, 1898, ser. i., 96-104; 1903, 125-9; Cook, *Journ. Agri.-Hort. Soc. Ind.*, 1904, 30-43; *Bull. Imp. Inst.*, 1903, 160-7; 1904, 32-8; *Trop. Agrist.*, 1905, xxv., 160-5, 199-200; *Board of Trade Journ.*, 1905, 134-5; Tschirch, *l.c.* 1008-9; Wright, *Rubber Cult. in Brit. Empire*, 1907, 20-1; Herbert Wright, *Cocoa*, 1907, 78-9; *Rubber Exper. in Bomb.*, in *Agri. Journ. Ind.*, 1907, ii., pt. i., 81; *Kew Bull.*, 1907, 103.

Chone orpha acrophylla, G. Don.; APOCYNACEÆ. A large climbing shrub met with in North and East Bengal and the moist tropical forests of India generally from Kumaon to Travancore. Recommended as worthy of trial as a new source of rubber, but from experience gained at Buitenzorg the subject does not seem encouraging. [*Cf. Kew Bull.*, 1896, 186; Manson, *l.c.* 4; *Bull. Imp. Inst.*, 1904, 160.]

Cryptostegia grandiflora, R. Br.; ASCLEPIADACEÆ. An extensive climber, fairly common on the western and southern tracts of India, and is stated to have been repeatedly cultivated with a view to the utilisation of both its milky sap and beautiful fibre. So long ago as 1893 the rubber prepared from it was reported on in England as "hardly equal to Ceara rubber from Brazil, although its general qualities are very encouraging." [*Cf. R.E.P., Comm. Circ.*, 1898, No. 2; *Ind. For.*, 1898, xxiv., 429; Dunstan, *Offic. Repts.*, 1903-4; Wright, *l.c.* 28.]

edysanthera 'crantha, A. DC.; Gamble, *Man. Ind. Timbs.*, 488; APOCYNACEÆ. A large climbing shrub common in the Darjeeling Himalaya at 3,000 to 5,000 feet, also in Assam, Sylhet, the Khasia hills and Burma. In Burma it is known as *nwedo*.

Recently a sample of the milk of this plant was furnished by the Conservator of Forests, Tenasserim, Burma, to the Reporter on Economic Products to the Government of India, with a view to obtain particulars as to the value of the caoutchouc and suggestions for a method of coagulation to be adopted with the milk. It was ultimately examined by Dunstan, who gave the analysis as caoutchouc 84.1 per cent., resin 11.5 per cent., and insoluble matter 4.4 per cent., with ash 1.3 per cent. The rubber was pronounced of a good quality. Further analysis will be necessary, the report continues, before the above results can be accepted as representative, but if furnished in quality corresponding with the sample analysed, it would be readily saleable.

The India-rubber Fig, Indian Caoutchouc Tree, the *bor*, *atah bor*, *kagiri ranket*, *lesu*, *yok bauwadi*, *nyauung kyet parung*, etc. The Karet rubber of West Java—a name which Manson points out may have been derived from the Burmese *kayet* (*kyet*).

A gigantic tree having its leaves and shoots perfectly glabrous, and which usually sends down from its branches numerous aerial roots. It frequently germinates naturally from droppings of birds, and is consequently often at first epiphytic. When under these circumstances it chances to become attached to another tree it grows slowly for the first six to ten years, and when its roots have reached the ground it usually kills the foster plant. It then grows more rapidly and becomes an immense and very lofty tree (from 100 to 200 feet in height). It is met with on

tions.

the outer Himalaya from Nepal eastward to Assam, the Khasia hills and Burma, being especially plentiful in the Hukong valley. It usually occurs in altitudes from 1,000 up to 3,000 or sometimes as much as 5,000 feet. It is now largely cultivated both as a shade or ornamental tree and as a source of rubber. For the latter purpose plantations were established in Java as early as 1872, and in Assam in 1874.

INDIA-RUBBER PLANTATIONS.—From the Assam Forest Department Reports of 1897-8 it may be learned that 88 acres were planted with this fig in Kulsi during 1873-7, and that in 1898 there were 2,411 trees on that plot having an average height of 87 feet 8 inches and mean girth of central bole of $6\frac{1}{2}$ feet; further that in 1878, 13 acres were planted, and the trees were in 1898, 81 feet in height and 9 feet in girth; that $25\frac{1}{2}$ acres were planted in 1883, and the trees on this extension were, when reported on, 67 feet in height and 5 feet in girth; and lastly that in 1884 there was a still further addition made of $33\frac{1}{2}$ more acres, the trees of which were found in 1898 to be 55 feet high and $4\frac{1}{2}$ feet in girth. In the report for 1904-5 (*Prog. Rept. For. Admin. Assam*, 9) it is stated that “ $56\frac{1}{2}$ acres were exploited, 4,100 trees tapped and 2,550 lb. of rubber obtained. The yield of rubber varied from $62\frac{1}{2}$ lb. per acre in the plantation of 1878 to $30\frac{1}{2}$ lb. per acre in Block II. of the plantation of 1883.” “The cost of tapping was Rs. 672 or annas 4, pies 3 per lb.; and of the rubber obtained, 1,488 lb. were sold for Rs. 4,020-6, or Rs. 2-11-3 per lb.; 3 lb. were kept as a sample and 1,059 lb. sent to London for sale.”

Charduar
Plantation.

In the Charduar plantation there were in 1898, 1,700 acres under this fig. Experimental tapplings were made in 1896-7 and 1897-8. These gave for 21 trees 46 and 48 lb. of rubber respectively, *i.e.* 2-19 and 2-29 lb. per tree. The rubber produced was in England valued at 2s. 3d. to 2s. 9d. per lb. In the report for 1904-5 it is said that “in the Charduar and Bamoni Hill plantations, Darrang Division, $367\frac{1}{2}$ acres were worked, 7,103 trees tapped, and 9,817 $\frac{3}{4}$ lb. of rubber obtained. The yield of rubber varied from nearly 37 lb. per acre in compartment 3 to $17\frac{1}{2}$ lb. per acre in compartment 11 of Charduar. In Bamoni Hill plantation only 5 lb. per acre were yielded, but this is accounted for by tapping being confined to small suppressed trees.” Home (*Ind. For.*, 1899, xxv., 70) estimates the annual yearly outturn from these Government plantations at 8,000 lb. of rubber, which at 2s. 8d. would give a gross return of Rs. 16,000 or a net return of Rs. 10,400, or say 9 per cent. on the capital cost of the plantations. But does this estimate include the cost of management, rent and interest? Plantations on a much smaller scale have been attempted in Madras and Mysore.

Seed.

PROPAGATION.—According to Claud Bald, “the prime requirements for raising this rubber are two: high, or well-drained land, and a hot steamy climate.” Fruit is produced from March to October, but according to Bald, the best seed is obtained in the hottest months, May, June and July. When collected the fruits or figs are dried in the sun and mixed with powdered charcoal to preserve them. They are about the size of peas, and at the time of sowing are broken up, and the seed thus sown mixed with portions of the disintegrated fruit. Light, sandy loam is most suitable for seed-beds and the best time for sowing would appear to be during the rains, *viz.* from June to September; but in some of the Government experiments the sowings are made in January and others in October. Bald recommends sowing in seed pans or boxes covered with glass. The seed is lightly scattered over the surface of the ground, and germinates about three months later. But the drainage of the beds must be perfect, and the ground allowed to become neither very wet nor very dry, and at the same time the plants

Seasons.

must be shaded from the sun for some time. When 2 to 3 inches high, the seedlings should be transplanted to a properly dug nursery-bed, well raised and drained. They should then be planted in lines about one foot apart. When 1 to 2 feet high, they may be put out in their permanent positions, but it is preferable to retain them in the nursery till they are 10 to 12 feet high, so as to prevent them being eaten by animals. In artificial planting it is found that rubber grows best on mounds. In the Kulsi plantation of Assam, lines are cut through the forest 20 feet wide and 50 feet apart from centre to centre. On these lines 15-foot stakes are put up 25 feet apart. Round each stake a mound is thrown up, 4 feet high, on which the rubber seedlings are planted. In the Charduar plantation the lines are 100 feet apart and the trees planted 50 feet apart, but the cleared lines of 20 feet were found insufficient and so were widened to 40 feet, thus effectually checking drip and affording the light necessary for full growth. The trees may also be propagated from cuttings, which must be from young fleshy shoots obtained by pollarding several branches of an old tree and allowing them to send out shoots. The best time to take cuttings is May and June. Both in Sikkim and Assam the epiphytic tendency of the plant has been simulated by tying seedlings or cuttings growing in baskets on to trees and allowing them to become attached to and to kill the trees in the way already mentioned. Gamble gives a full account of the methods of propagation pursued in various plantations which the reader should consult, as also the pamphlets by Bald and Coventry.

Transplanting.

Cuttings.

Epiphytic
Tendency.

INDIAN CAOUTCHOUC.—Most of the India-rubber procured from India has been collected from wild trees in the natural forests. It is collected by the hill tribes in tracts beyond the British frontier, and sold to the people of the plains in the form of balls that have to be carefully examined for stones or mud placed in the centre. The Government plantations have recently begun, however, to contribute a superior rubber, the proportion of which is likely to be yearly increased. The latex is collected during the dry months. Eight oblique cuts are made on the main stem, sloping downwards and at a little distance from each other. The best tool for making these incisions is said to be a carpenter's gouge worked with a small mallet. These incisions should not be deep, as the milk is secreted just below the outer bark, and the lowest should be about 4 feet from the ground. Below the incisions pots or *kalsies* are tied round the tree one underneath the other, which are left attached for the day. The trees should be tapped only once in three years. If tapped yearly they are liable to die. A few spoonfuls of a watery solution of alum are usually put in each vessel of milk, after it has been purified of extraneous matter. The milk coagulates and the rubber is exposed to air on sticks and allowed to drain for a week. In a month it is ready for the market. The yield from each tree in the Assam plantations at the present day is approximately 8 oz. per annum, and the average age of the trees is about 26 years; but according to some writers, the trees may be tapped at 14 years. E. S. Carr's remarks (*Ind. For.*, June 1905, xxxi., 335-7) regarding method of tapping pursued in Assam and the coagulation of the rubber should prove instructive to those interested in the subject, and an article by Mann (*The Tapping of Assam Rubber*, in *Agri. Journ. Ind.*, 1907, ii., pt. iii., 277-9) should also be consulted.

Recent Publications.—Mann (*l.c.* 393) reviews in a forcible manner the opinions and conclusions arrived at by Bald, Coventry and Eardley-Wilmot (in the most recent publications mentioned above on the subject of Indian *Ficus elastica*). He writes, "The factors which will determine the practical success of Assam rubber may perhaps be set out as follows:—

Governing
Factors.

- (1) "The initial or capital cost of forming a rubber plantation and bringing it into bearing.
- (2) "The age at which the trees will commence to yield.
- (3) "The yield which may be expected per tree and per acre.
- (4) "The cost of working a bearing plantation, collecting the rubber, and placing it on the market.
- (5) "The value per pound of the rubber produced.
- (6) "The permanency of the plantation."

Mr Ma endeavours to obtain from the publication in his hands an answer to each and every one of these issues, or to show where and in what way available particulars are wanting. His object is, from first to last, to ascertain if experience and knowledge obtained in North-East India justify extended cultivation by private enterprise, and the form which it should assume. As he confesses, his

conclusions are disappointing. He continues, "The prospects are so doubtful, and even if successful so poor as compared with the culture of Para or Castilloa rubber in Ceylon, the Malay States, or even South India, that one is inclined to consider any large extension of the culture of *Ficus elastica* in North-East India as out of the question. And I must say that this impression has been very strongly confirmed by almost all that I have seen in these districts, if the Assam rubber is to be cultivated as a separate industry. On the present evidence the length of time which it is necessary to wait for returns, the smallness of the returns when they are obtained, the doubt as to the market fifteen or twenty years hence, would seem to make investment in Assam rubber culture, as a separate venture, a very doubtful speculation in North-East India at any rate. I do not see how, at the rate of outturn obtained now at Tezpur, more than Rs. 15 to Rs. 18 per acre profit could be obtained per annum; and even if this were multiplied by four it would hardly be attractive enough to induce an investor to wait over twenty years for the result. In fact, the only possibility of *Ficus elastica* culture would seem to be as a by-product to tea culture, on land now waste and unsuitable for tea. In this case, the growth of Assam rubber may afford a means of turning land to profitable account which would otherwise only remain useless to its owners. It may be that future discoveries with regard to improved methods of tapping, new methods of growth, means of tapping the plants annually without injury, or of growing a larger number of healthy heavily-yielding plants on the same area, may alter the opinion above expressed. But as it stands, and with the data before us in the two pamphlets under review, I feel that no other conclusion is possible than that Assam rubber culture can only continue as a dependent of another larger and more profitable industry, and then can only occupy the inferior land."

Chemistry.—A representative sample of 1903-4 rubber from the Charduar rubber plantation was submitted to analysis in the Scientific and Technical Department of the Imperial Institute, and gave the following results:—The rubber was of a reddish-brown colour, but showed here and there small white patches. It was highly elastic and tenacious, dry, clean and free from stickiness. It was completely soluble in chloroform, carbon disulphide and benzene, and partially in ether. The analysis was as follows:—caoutchouc 76.67 per cent., resin 19.2, albuminoid matter 1.5, dirt and insoluble matter 1.7, moisture 0.9, ash in dirt 0.5. A high percentage of resin appears characteristic of rubber from the Charduar plantation. No precise data are available to show how the composition of rubber varies with the age of the tree or locality from which produced. A specimen of Assam rubber examined by Hooper gave the following:—resin 12.65, caoutchouc 85.95, water 1.0 and mineral matter 0.40, while a sample of Andaman rubber (from this tree) gave resin 4.87, caoutchouc 67.06, water 27.57 and mineral matter 0.50 per cent. There is thus a wide diversity in composition which it seems essential should be explained.

Trade.—The imports into India across its land frontier, more especially into Assam, are considerable. During the year 1901-2 these came to 1,470 cwt., valued at Rs. 1,55,656; in 1902-3, 733 cwt., valued at Rs. 65,912; in 1903-4, 1,601 cwt., valued at Rs. 1,66,629; in 1904-5, 3,083 cwt., valued at Rs. 3,50,773; in 1905-6, 2,587 cwt., valued at Rs. 3,56,413; and in 1906-7, 2,330 cwt., valued at Rs. 3,03,194. Of these amounts a very large proportion usually comes from the Naga and Mishmi hills. Recently the Government plantations have begun to contribute to the annual supply something like 3,000 lb. The exports from India to foreign countries in caoutchouc (mostly the produce of *F. elastica*) were in 1903-4, 1,792 cwt., valued at Rs. 3,47,196, and in 1906-7, 4,489 cwt., valued at Rs. 11,18,487; but the traffic fluctuates very greatly, especially the supply drawn from Burma, for in 1899-1900 the foreign exports were returned at 8,169 cwt., valued at Rs. 15,80,729. These foreign exports are usually drawn from Bengal (including Assam) and Burma, and are consigned chiefly to the United Kingdom and the United States. In a report furnished by the Director of the Imperial Institute (Feb. 3, 1905) the value of the Charduar rubber is stated to have been 3s. 8d. per lb. on the London market. For

insulating purposes, however, the value of this rubber is stated to be only 3s. 3d. per lb., owing to the large quantity of resin which it usually contains.

Para or Hevea Rubber.

veea brasiliensis, Mull. Arg.; Hemsley, *Kew Bull.*, 1907, 154; EUPHORBACEÆ. The PARA RUBBER TREE. This and one or two allied species occur in the forests of Central and Northern Brazil, and in the forests of Para from the mouths of the Amazons, south and west. They all yield rubber. The region indicated has a climate remarkable for its uniformity of temperature, 87° F. midday and 74° F. at night, the mean being 81° F. and the highest record 95° F. The rainfall occurs principally in January to June, the maximum being in April, when it reaches 15 inches. It is a very healthy region with a remarkably fertile and continuously moist soil. The trees grow rapidly and attain some 30 feet in three years.

By far the best rubber is obtained from the species of this genus. In fact, where *Hevea* can be profitably grown it will never pay to cultivate any other rubber plant. The rubber afforded is stronger and possesses a much higher breaking strain than that of any other plant, its tenacity being due, so it is thought, to the method of coagulation. Once established, *Hevea* requires but little care, and rough weeding will suffice. It is, however, liable to several pests, more especially canker, and has to be protected from browsing animals (deer, etc.) when in the young plantation stage. The trees may be tapped when about six years old, but they come into full bearing in eight to ten years. Success is closely connected with the methods of tapping and curing pursued; absolute cleanliness is indispensable. The bark of the trees about to be tapped should be first cleaned and the V-shaped cuts on the perpendicular central channel made with decision and thoroughly cleansed before the milk begins to flow. Dust, sand and other impurities greatly lower the value of the rubber, since they can with difficulty be subsequently removed. Deliberate adulteration once proved will permanently ruin a plantation or source of supply.

Protection Necessary.
Six-year-old Tappings.

Method of Tapping.

INDIAN ACCLIMATISATION.—This rubber tree has been successfully cultivated in Mergui and Tavoy. It has also been fully acclimatised in the south-west districts of Ceylon, where so much attention has been paid to the preparation of the rubber that it has actually fetched a higher price than that from the indigenous home of the plant; but while, owing to its purity, it is valuable for waterproofing, it seems to lack the tensile strength of the rubber of Para.

Indian Production.

Burma.—In the *Dictionary* will be found a brief review (an abstract from Thiselton-Dyer's report) of the historic facts regarding the introduction of this plant into Asia from seed germinated at Kew. The first endeavours in Burma date from a small consignment of plants sent to Mergui by Sir

History.

Mergui
Plantations.

Yield.1

Enterprise.outh
India.

engal.

George King in 1877. A second consignment was obtained in 1879 from Ceylon. In 1884 some of the better established plants began to seed, and an acclimatised stock of seedlings was thereby obtained. Manson, in his *Short History of the Mergui Rubber Plantations of that Province*, has carried the record to the present date. In May 1900 sanction was accorded for the gradual formation of a plantation of 10,000 acres of *Hevea* trees. This was to be located, 5,000 acres in the Sandawut reserve and a similar area on King Island. The work was started in 1901 by 46 acres being planted out, 12 by 12 feet. By 1904, 1,518 acres had been planted, and the operations have since been vigorously prosecuted, annual extensions taking place according to the scheme sanctioned. The purpose in view has been to demonstrate the commercial possibilities of this rubber cultivation in Mergui. Already 929 lb. of rubber have been produced, and the nurseries, according to the last report, contained 600,000 plants, with an addition of 100,000 self-sown seedlings in the original experimental garden. In the *Annual Report Forest Administration of the Tenasserim Circle* (1904-5, 31-3), W. F. L. Tottenham, Conservator of Forests, gives the results of a further year's efforts. The total amount of dry rubber collected during 1904-5 was 1,450 lb., of which 54 lb. 6 oz. were collected during the rains. The cost of collection came to about 11 annas per lb. The area was intended to have been extended by 1,250 acres, but owing to an outbreak of cholera only 818.65 acres were added to the plantation. Of that expansion 736.87 acres were in Mergui, and 81.78 acres on King Island. The conservator of the Northern Circle (*l.c.* 52) says that *Hevea* has not proved a success in the Katha Division. Hooper (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1906-7, 6) mentions the result of examination of a sample taken from a white-ant's nest (*Termes gastroi*). The rubber was of great excellence, the resin having apparently been extracted by the ants.

Thus, then, it may fairly be said that Brandis, who early foretold success for Tenasserim Para-rubber cultivation, has been abundantly confirmed, and the future seems destined to see large developments. Already private enterprise is engaged in the business, and doubtless when the possibilities in this direction of its forest property have been fully established, Government may withdraw. (*Ind. For.*, Sept. 1905, xxxi., 330-4). For methods of propagation and systems of tapping the trees, consult the technical publications, more especially the circulars issued by the Director of the Royal Botanic Gardens, Ceylon.

South India.—A good deal of interest has recently been taken in the possibility of Travancore and even of Mysore becoming hopeful localities for Para-rubber cultivation. It is said by planters and others that thousands of acres of heavy forest-land, below 1,000 feet in altitude, exist that possess rich soils and a liberal rainfall, eminently suited for rubber, but which at present are valueless because not put to any purpose. Some progress has, however, been made, but taking South India as a whole, Para rubber has not so far been the unqualified success anticipated. A writer in the *Madras Mail* (March and April, 1905) seems to take a hopeful view, however, and the subject has by no means been abandoned.

Bengal and Assam.—Considerable efforts have been made to organise Para-rubber plantations in Northern and Eastern India, but with little encouragement so far. The trees have been planted out in Kurseong, Jalpaiguri and Buxa, but the reports of the Forest Department cannot be said to be favourable. [*Cf. Mann, Cult. of Para Rubber in North-East Ind.*, in *Agri. Journ. Ind.*, 1907, ii., pt. iii., 273-6.]

Landolphia Kirkii, Dyer, and **L. owariensis**—East and West African Rubbers; APOCYNACEÆ. A genus of climbing plants, met with in Africa, of which several species afford rubber. To Sir John Kirk is due the honour of having first directed attention to these plants. Sir George King, in the Annual Report of the Royal Botanic Gardens of Calcutta for 1880-1, reported the germination of seeds obtained through Kirk. The plants unfortunately, however, subsequently died. At the Nilambur plantation of the Nilgiri hills, further efforts were made to acclimatise this plant. About the same time thirty-four plants were reported as doing well in South Malabar. In the report of the Government Botanic Gardens, Bangalore (1897-8), it is spoken of as growing like a weed. In the Report for 1902-3, Cameron wrote: "Much nonsense has been written lately concerning a new rubber plant *Landolphia Thollonii* found on the French Congo." . . . "The latex of this little shrub, which is only half a foot high, is chiefly stored in the root." "The African genus *Landolphia* promises to be a large one, and doubtless all the species may be found to contain latex. We have one or two species on trial which grow well. But as climbing plants they are not, in my opinion, very suitable for rubber-farming in this country." Manson (*l.c.* 8) observes that the *Landolphas* have recently been tried in Mergui and in the Rangoon Division of Pegu Circle. [*Cf. Ind. For.*, 1882, vii., 233-7; 1897, xxiii., 61-3; 1900, xxvi., 129-34, 313-30; *Annals of Botany*, 1900, xiv., 203; Christy, *New Comm. Pl.*, No. 1, 8-10, and plate; No. 6, 54-6; *Kew. African
Rubber.

Introduction
into India.

anilhot laziovii, Mull. Arg.; EUPHORBIACEÆ. Ceara Rubber, Scrap Rubber, Manicoba Rubber. Cross described the tracts in Brazil where he found this plant as possessing a dry arid climate for a considerable part of the year. The rainy season, he says, begins in November and continues till May or June, though there are occasionally almost rainless years; the temperature ranges from 82° to 90° F., and the altitude is about 200 feet above the level of the sea. Ceara is a coast town in lat. 4° S.

D.E.P.,
iv., 374-8.
Ceara
Rubber.

In the early experiments at acclimatisation of rubber trees in India (1876 and subsequently) it was ascertained that while Ceylon had better be treated as the centre of the experiments with *Hevea* and *Castilloa* rubbers, Calcutta might with advantage be made the depôt for Ceara. Sir George King accordingly wrote, in the Annual Report of the Royal Botanic Gardens of Calcutta for 1880-1, that the Ceara rubber trees continue to grow vigorously, and a few are now beginning to yield seed. In the same year, in the Annual Report of the Botanic Gardens, Nilgiri Hills (Barliar), it is said that the Ceara trees are now completely established. Lawson, for example, wrote that Ceara trees "grow very rapidly, and to all appearance thrive well; but I have been wholly unable to extract rubber from them in anything like a paying quantity, and every one else hitherto has also failed." In the report for 1890-1 the record is made of eight trees having been tapped for rubber. In the Report of the Conservator of Forests, Madras (1891-2) it is stated that in North Malabar this rubber tree grows like a weed and some of the trees are 46 feet high. In 1895-6, 309 trees were tapped in South Malabar and gave an average of 1 oz. per tree of dry rubber, valued in England at 1s. 6d. to 1s. 9d. per pound. Mr. R. L. Proudlock, in 1898, tapped a tree eighteen years old the Barliar garden, and by a single tapping obtained 2½ oz. of dry rubber. Ceara, he adds, is quite at home and will grow almost anywhere on the Nilgiris up to 4,000 f t al-

South India.

ilk Creeper

titude. Mention is often made of a fairly extensive cultivation in South Coimbatore. Cameron (Superintendent of the Botanic Gardens, Bangalore) has repeatedly reported on this rubber. Experiments were commenced with it as early as 1879. After enumerating the production and distribution of seed from the gardens during the past twenty-five years, he adds that Ceara rubber is now tolerably common in many parts of the Province. In a report published in the *Mysore Gazette*, April 1904, he further gives useful particulars of planting, propagation and tapping of the trees. In the *Forest Dept. Reports of Burma* mention is made of successful acclimatisation in Mergui. In 1896 a valuation of 2s. a pound for the rubber was obtained.

Experience
Attained.

It is hardly necessary to deal with other reports since enough has already been furnished to give a fairly satisfactory conception of the efforts made and results attained in India. But it may be useful to conclude with the following as indicating the opinions held by experienced scientific authorities in Europe:—The *Kew Bulletin* summarises the results obtained somewhat as follows:—1. The plant is readily propagated by seed or cuttings. Seeds are abundantly produced in almost every part of the world where the plant has been introduced. Sowing in the permanent position is universally adopted in Brazil. 2. The Ceara rubber plant is very hardy, a fast grower, free from insect and fungoid attacks, requires little or no attention when once established, and thrives in poor, dry, rocky soils unsuited to almost any other crop. Large plantations only are likely to prove remunerative. 3. It produces a good class of rubber, second only to the best Para. The yield is small per tree, but a return is obtained earlier than from any other species. Under skilful treatment the trees may be tapped twice yearly, and last in a productive state for fifteen to twenty years. 4. In spite, therefore, of the apparent want of success in Ceylon and other countries, the increasing importance of rubber suggests a reconsideration of the merits of this interesting plant.

Starch-yielding
Tubers.

Both in India and Burma mention is made of the fact that the large starch-yielding tuberous roots of this tree have been discovered by the wild pigs, and considerable damage done by them in seeking out and devouring the tubers. This fact suggests the possibility of these starch-yielding tubers becoming an additional source of revenue, should an extended cultivation take place. [*Cf. Cross, Ind. For.*, 1879, iv., 27-45; *Notes Ceara Rubber in Ind. For.*, 1882, viii., 58-61; 1897, xxiii., 456-8; 1898, xxiv., 460-1; *Proc. Madras Board Rev.*, Oct. 1894, No. 712; Nov. 1897, No. 914; 1899, No. 518; Aug. 1904, No. 906; Morris, *Cant. Lect.*, l.c. 1898, 765-70; *Kew Bull.*, 1898, 1-15; R.E.P., *Comm. Circ.*, 1897, No. 8; 1901, No. 4; *Rept. Bot. Gard. Nilgiri Hills*, 1902, 8; 1902-3, 9-12; 1903-4, 5-8; *Imp. Inst. Tech. Empire*, 1907, 21-2; Wright, *Cocoa*, 1907, 79.]

D.E.P.,
iv., 361.

Para eria glandulifera, Benth.; APOCYNACEÆ. The Talaing Milk Creeper. A large climbing evergreen shrub of the borders of tidal forests on the sea coasts of Tenasserim and the Andaman Islands. It is known as *talaingzok* in Burma. It would appear to have sometimes been confused with *Willoughbeia edulis*. The milk is obtained by a somewhat destructive method of cutting the stem into short lengths, and allowing the milk to drain into vessels containing water at a temperature of 104° to 122° F. On agitation the milk coagulates. The plant may be propagated by cuttings with great facility. The yield seems to be remarkably high and the rubber of fair quality, perhaps equal to that of *Ficus elastica*. Hooper (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1906-7, 6) gives the analyses of three samples examined. They contained 92.39, 95.1 and 96.7 per cent. of caoutchouc. A sample from the Andam Islands he found (l.c. 1905-6, 25) contained 92.5 per cent. of caoutchouc, 6.4 per cent. resin and 1.0 per cent. ash. In spite, therefore, of all that has been said to the contrary, this source of rubber seems worthy of more careful consideration than has as yet been meted out to it, and it seems probable that some cheaper and more economical process of collection might be devised than that practised at present, while the cost may be brought within permissible commercial limits.

Propagation.
Yield.

Method of
Collection.

In this connection it may be added that the percentage of ash is an important factor in determining the values of rubbers. The following average returns may, therefore, be of interest:—Para rubber, 1 to 2.5 per cent. ash; Ceara rubber, 2 to 3 per cent. ash; Assam rubber, 4 to 6 per cent. ash; Parameria rubber,

6.4 per cent. ash in dry rubbers. [Cf. Wright, *Rubber Cult. in Brit. Empire*, 1907, 28.]

hynchodia Wallichii, Benth.; APOCYNACEÆ. A lofty evergreen climber of the Sikkim Himalaya at altitudes of 2,500 feet, also met with in Assam, Sylhet and Burma. Attention has recently been directed to this plant as a new source of rubber by Mr. Hearsey of the Forest Service, Burma. A sample of the rubber was furnished in August 1903 by the Reporter on Economic Products to Prof. W. R. Dunstan for examination. The report, dated May 1904, shows the rubber to contain 89.0 per cent. caoutchouc, 6.7 per cent. resin, 4.3 per cent. dirt, and 0.51 per cent. ash (included in the dirt). It is thus of good quality, but about 1.5 per cent. of the caoutchouc was insoluble in the usual solvents. The brokers' report on the sample was to the effect that, at present prices, it would realise 3s. 6d. per lb. Dunstan then adds that if supplied of similar quality to the sample examined, it would always sell readily.

Valuation.

Sapiu biglandulosu, Muell.; EUPHORBIACEÆ. Yields Colombian Scrap or Virgin Rubber from British Guiana and also Bolivian Rubber. [Cf. *Kew Mus. Guide*, 1907, 189.]

Urceola elastica, Roxb., and **U. esculenta**, Benth. (*Chavannesia esculenta*, A. DC.); APOCYNACEÆ. These climbing shrubs yield caoutchouc of good quality. The former occurs in Malacca and Penang and the latter in Burma; common all over Pegu and met with in Martaban and Tavoy. It is known as *kyetpanng* (Burma) and *tophet* (Karen).

D.E.P.,
iv., 361-3.

This rubber appears to have been first described by Dr. Thomson in 1858, subsequently by Mason (1860), and in 1874 Strettell wrote a special illustrated pamphlet on the subject (*The Caoutchouc obtained from Chavannesia esculenta*). Sir W. T. Thiselton-Dyer, as in the case of all the other rubber-yielding plants, contributed largely towards the development of our knowledge of the present species. The *Forest Administration Reports of Burma* contain, almost yearly, numerous brief references to it and its rubber. In 1897-8, for example, mention is made of 2,342 plants being in the Palon and Kimpadi Plantations of Rangoon, which were started in 1874. Perkin (*Circ. R.B.G. Ceylon*, 1899, 162) observes that "the latex from the thin stems, such as bear the leaves or have recently shed them, forms a sticky substance when moulded between the finger and thumb. The plant resembles *Castilleja* in this respect. The latex both from the pith and the cortex of the young stem is sticky, hence it looks as if the true caoutchouc is only formed in the secondary bast." Manson (*l.c.*, reprinted as *Comm. Circ.*, 1901, No. 4, 12) gives many useful particulars.

Burma Supply.

In the *Proceedings of the Government of India (Forests*, June 1904, No. 5, 18-9) a collection of official communications has been brought together, extending from May 1903 to January 1904, that gives the most recent experience and results in tapping the *Urceola* plants in the special plantations of this species. They can hardly be regarded as conclusive, though highly instructive. On March 21-5, 1900, 469 creepers were tapped, each with thirteen cuts, and the yield came to 11.454 lb., which was not weighed till April 20, 1903. This cost Rs. 29, or Rs. 2.53 per pound. The second tapping took place on December 14-24, 1900, of 508 creepers, each receiving 30 cuts and yielding 9.853 lb. of rubber, which was weighed on January 25, 1901, and estimated to have cost Rs. 51.4 or Rs. 5.20 per lb. The writer of the report accordingly comes to the "conclusion that the cost of collection of the rubber of *Chavannesia* is prohibitive, and that no profitable industry can ever be developed in connection with it." But as if to show that the experiments conducted and the conclusions drawn from these cannot be regarded as final, he adds that in the Mon Valley in Minbu district the monopoly of collecting rubber from *Chavannesia* is sold annually by auction for Rs. 250. It is thus clear that better results can be and are obtained than in the special plantation of this plant near Rangoon. Subsequent experiments seem to show that the tappings mentioned are not necessarily conclusive of what can be done at the plantation.

Results.

Indigenous
Production.

Dunstan, reporting in May 1903 on samples of this rubber, furnished to him for that purpose, observes that this plant yields "a rubber which promises to be of some commercial importance, especially if it can be forwarded in large consignments of the quality represented by the sample now reported on." The analysis showed caoutchouc 81.8 per cent., resin 7.5 per cent., dirt 10.7 per cent., and ash (included in dirt) 1.8 per cent., calculated on dry rubber. The commercial experts consulted compared the rubber with

Valuation.

Tonquin, and gave its valuation at 2s. to 2s. 1d. per lb. Dunstan then adds, "This material is evidently deserving of further attention." *The Agricultural Ledger* (1903, No. 10) gives the results of additional chemical investigations conducted by Leather, as also a note by Mr. S. Carr, Deputy Conservator of Forests, in which the methods of collection of the latex are described.

Valuations.

Subsequent samples were forwarded to the Imperial Institute for examination. It was reported that three contained so high a percentage of resin as to throw doubts on their being correctly determined botanically. The others showed a high percentage of good caoutchouc, and were valued in 1904 at from 3s. to 4s. a lb. [Cf. Morris, *Cant. Lect., l.c.*, 1898, 792; *Bull. Imp. Inst.*, Sept. 29, 1904, 156-9; Wright, *Rubber Cult. in Brit. Empire*, 1907, 28-9.]

D.E.P.,
iv., 3 8-4.

Willoughbeia edulis, Roxb.; APOCYNACEÆ. The *thitchanknwe*, possibly also *tulaingno* of Burma, and the *lati-am* of Bengal, is an immense climber met with in the forests of Assam, Sylhet, Cachar, Chittagong, Pegu, and Martaban. It yields a large edible fruit, which from a general resemblance to the mango has suggested the name "climbing mango." At one time high expectations were entertained regarding *Willoughbeia* rubber. It has since transpired that much of the rubber in question will have to be transferred to other genera, and that so far as the Indian species is concerned (*W. edulis*), it must be no longer considered as a caoutchouc-yielding plant. Recent investigations conducted by Dunstan have shown, for example, that the very high percentage of resin (in some samples 84.6 per cent. with only 10.8 per cent. caoutchouc) necessarily exclude it from consideration as a rubber. [Cf. Wright, *l.c.* 29.]

Low Yield of
Caoutchouc.

Trade.

Trade in India-rubber and Caoutchouc Manufactures.—Such particulars (p. 654) as can be procured regarding the production of caoutchouc in India have been given. It remains to exhibit very briefly the traffic in rubber manufactures. There are no local (Indian) manufactures, so that the supplies of goods are drawn exclusively from foreign countries. In 1876-7 the imports of raw caoutchouc and of india-rubber manufactures collectively were valued at Rs. 1,27,759; twenty-five years later (1900-1) they came to Rs. 6,05,594; in 1903-4 to Rs. 7,03,003; in 1905-6 to Rs. 7,78,905; and in 1906-7, Rs. 10,04,782.

It may be here added that the imports into Great Britain during 1902 came to 419,375 cwt., valued at £5,180,262, and in 1906, 607,077 cwt., valued at £9,966,620. Of the last-mentioned amount Brazil alone contributed 253,918 cwt., and the total from British Possessions was 90,453 cwt. The exports equal about one-half the supply (330,252 cwt. in 1906)—the country which takes the largest amount being the United States (126,969 cwt. in 1906).

Indi o.

INDIGOF A (INDIGO), the Dye-yieldi pecie .—A

genus of LEGUMINOSÆ which comprises some 300 species, distributed throughout the tropical and warm temperate regions of the globe—India having about 40. Western India may be described as the headquarters of the species, so far as India is concerned, 25 (thus fully half) being peculiar to that Presidency. On the other hand, on the eastern side of India (the provinces of Bengal, Assam and Burma) there is a marked decrease in the number of species but a visible increase in the prevalence of those that are met with. It is possible, moreover, that many more species afford indigo than those specially cultivated for the dye. Accordingly, cultivation of richer dye-yielding stocks has been urged as one of the most rational methods of improvement. [Cf. Watt, *Anal. Trade and Comm. of Ind., Madras*, 1899, 4.] This is of supreme moment in the crisis that has overtaken the industry. Prain and Baker (*Notes on Indigofera*, *Journ. Bot.*, 1902, xl., 60-7, 136-44) have furnished a very instructive paper, which has already proved of the greatest practical value. So also

Improvement
by Selection
of Stock.

Leake (*The Localization of the Indigo-producing Substance in Indigo-yielding Plants*, *Journ. Roy. Hort. Soc.*, 1905, xxix., pts. 1-3; *Annals of Botany*, 1905, xix., 297-310) has devoted much attention to the selection of stock, and the practical results to be attained thereby. Space cannot be afforded here to do more than review very briefly the salient features of these and other special studies. This will be attempted while following the usual rule of treatment in alphabetical sequence of scientific names :—

Indigofera Anil, Linn.; *Mant. Pl.*, 1771, 272; Prain and Baker, *l.c.* 137-40. This South American species is grown in Burma, Eastern Indo-China and Southern China, but never, so far as we now understand, in India proper. Moreover, there would appear to be three very distinct varieties (or perhaps more correctly distinct species, closely allied to *I. Anil*) that have to be dealt with in this position. These are :—

(α) *I. truxillensis*, H.B.K.; *I. tinctoria*, var. *oligophylla*, DC. An American species and very common plant. It apparently was the form chiefly cultivated in the West Indies during Sloane's time, and is the wild indigo of West India writers. (β) *I. Anil*, Linn., var. *polyphylla*, DC.; *I. suffruticosa*, Miller, *Gard. Dict.*, 1768 (ed. viii.), No. 2. This is the cultivated plant—*Xvhwqvilil pitzahac* of Hernandez (*Nova Pl. Hist.*, 1651, 108), the wild form of which is the *I. guatimala*, Lunan (non Linn.). (γ) *I. Anil*, Linn., var. *orthocarpa*, DC.

I. argentea, Burm. (non Linn.), *Fl. Ind.*, 1768, 171, an Indian plant that is quite distinct from *I. articulata*, though often confused with it.

I. arrecta, Hochst. (*Schimp.*, *Herb. Abyss. Pl.*, n. 1923, non Benth), in Richard, *Fl. Abyss.*, i., 184. The Natal-Java Indigo. This is the well-known *degendeg* (dek indig) of Abyssinia and the chief indigo-producing species of Africa outside the area occupied by *I. articulata*. It is now largely cultivated in Java under the name of Natal Indigo. Of Java, Prain (in a letter to Barber) says, "In the beginning only *I. tinctoria*, probably introduced from India or Ceylon, was grown. This, however, towards the end of the seventeenth century, was replaced by *I. sumatrana*, which held its ground for a considerable time. In the West Indies and Brazil the cultivation began with *I. sumatrana*, which was imported as 'Brazil Indigo.' Later on, however, this plant was displaced by a native species *I. truxillensis*, which soon was supplanted by another and better native species, *I. Anil*. This species, *I. Anil*, has spread all over the world and is even now the most widely grown of the dye-yielding indigoes; when it reached Java it displaced *I. sumatrana*. In the West Indies *I. Anil* finally met with a formidable rival in *I. guatimalensis* and in course of time the latter, being recognised as a superior kind, was adopted in Java to the exclusion of *I. Anil*. More recently in Java *I. guatimalensis* has been found to be less valuable than *I. arrecta*, and the latter has practically taken its place. The historical aspect of the subject therefore indicates the advisability of at least giving a trial to *I. arrecta* in Madras. It does not, of course, follow that the plant will thrive, but if it does, it seems clear that it is the best species to grow. In Bihar, where it has been carefully tried, there are objections to the plant which it is hoped may be overcome; but in Lower Bengal it thrives much better than *I. sumatrana*. The advantages of the plant are twofold. It gives much more leaf, being a much larger plant, and it is stated by those interested in the preparation of indigo to give a higher percentage of dye from the same weight of leaf."

The objections to which Prain refers have been ably dealt with by Leake. The plant was found to germinate so imperfectly as to render its cultivation unprofitable. It has the same defect as clover, namely, the seed-coat is very hard (Bloxam and Leake, *Acc. Research Work in Indigo*, 1905, 33). What is, therefore, required is a machine that will scratch the seed-coat and thus facilitate germination. Recently in the public press of India it has become customary to read of "Natal-Java seed scarified and ready for sowing" (see p. 671). Bergthell (*Ann. Rept. Imp. Dept. Agri.*, app., 1904-5) observes that the Java plant contains more potential colouring matter than do any of the plants ordinarily cultivated in Bihar. Mr. H. A. Bailey, who visited Java in 1899 on behalf of the Indigo Improvements Syndicate, was apparently the first person who pointedly directed the attention of Indian planters to this stock. F. M. Coventry furnishes returns which would seem to justify the opinion that the Java plant shows an increase of 35 per cent. in the amount of green plant cut per acre and of 45 per cent. increase in vat produce, over the ordinary plant of the United Province.

Egyptian.

I. articulata, Gouan, *Illust.*, 1773, 49. This is *I. argentea*, Linn., *Mant. Pl.*, ii., 273, non Burm.; *I. spicata*, Forsk.; *I. cœrulea*, Roeb. Is the plant which yields much of the indigo of Arabia and Egypt, still sometimes met with in Western India and as far to the east Bandelkhand and the Kistna highlands. Was formerly the species most largely grown in the Bombay Presidency, but nowadays is only occasionally seen under cultivation in Rajputana and Sind. Prain says that in the time of Roxburgh and Hamilton (1803-14) the Egyptian indigo still survived as an Indian species (probably escaped from cultivation) in Bihar, but now it seems to have quite disappeared from that region.

I. longerace osa, Boivin, *Herb.*; Baillon, in *Bull. Soc. Linn. Paris*, 1883, pt. i., 399; Prain and Baker, *l.c.* 144. In the letter by Prain, to which reference has already been made, there occurs the following passage:—"In Madagascar and Zanzibar there is a species—*I. longeracemosa*, very distinct both from *I. tinctoria* and from *I. sumatrana*—that is valued by the people of these islands beyond all the other species they grow, and they grow the following:—(a) and chiefly *I. Anil*, (b) less often *I. tinctoria*, (c) occasionally *I. sumatrana*, and (d), in the highlands of Madagascar, *I. arrecta*." Prain then adds that as long ago as 1875-6, Col. Beddome found this very species both in Travancore and Tinnevely, and subsequently it was found by Lawson in Travancore.

Forms of
Tinctoria.

I. tinctoria, Linn., *Sp. Pl.*, 1753, 751. Prain and Baker establish two chief varieties of this species with several very distinct cultivated states under these, some of which may have to be viewed as worthy of distinct specific positions. The following abstract may be regarded as setting forth the salient points:—

(a) *var. acrocarpa*, DC. The special forms of this are:—

THE WILD PLANT, apparently unknown to Linnæus or De Candolle. It was found in Nubia by Kotschy in 1841, and specimens which agree with it in every essential have also been found in Central India. Regarded as a distinct species its name would be *I. Bergii*, Vathe. [Cf. Duthie, *Fl. Upper Gang. Plain*, i., 255.]

Madras Stock.

THE SOUTHERN OR MADRAS AND CEYLON cultivated stock. This is the plant dealt with by Linnæus in his *Flora Zeylanica*, and by Burmann in his *Flora Indica*. This particular form would thus appear to have been early cultivated in Southern India, though recently it has very possibly been completely displaced by *I. sumatrana*. "It was and still is the *I. tinctoria* of the cultivators in the Dutch Indies, where, however, the species is not now much in favour. Specimens of this form, evidently feral after escape, have been communicated from many places both within and beyond the limits of the area where it now is, or formerly has been in cultivation." Prain and Baker, from whom the above has been derived, add that they have seen specimens of this particular plant from the Philippine Islands; from North Queensland; from the Laccadives, where it is described as forming thickets that cover a great portion of Kadamun Island; finally from Merwara in Rajputana, where it is not, and probably never has been cultivated. It is a wild plant in Merwara, growing by the sides of ravines, and bears the vernacular name of *jinjini*.

Northern Stock.

THE NORTHERN CULTIVATED FORM.—This is largely in use in Northern India from Bihar and Tirhut westward by north to the Panjáb, where its area meets that in which some form of *I. argentea* is grown, and southward to the Circars, where *I. tinctoria* occurs. This, throughout the area specified, is the plant known as *nîl*, and is the form to which the name *I. tinctoria* is applied. "It is not exactly what Linnæus meant by *I. tinctoria*: it is, however, precisely what Gaertner intended by *I. sumatrana*, and what Lamarck has figured as *I. indica*, but not the same thing as the old *I. indica* of Miller, which is *I. hirsuta*, L." (Prain and Baker, *l.c.* 65). In the Annual Report of the Royal Botanic Gardens, Calcutta, for 1901-2, it is observed that while the Dutch held possession of Malabar this indigo plant, "apparently derived from the Eastern Malaya, came into use there." Prain (in the letter above mentioned) observes: "About that time, 1686, there was cultivated in Malabar a different plant, *I. sumatrana*, which seems to have been introduced a little later (whether from Malabar or directly from the Malaya cannot be traced) into Bengal, where prior to its introduction, indigo was not grown at all. This plant, which generally passes under the name of *I. tinctoria*, although it is not precisely the same as the true plant of that name, has now spread gradually westward and has driven out almost completely the cultivation of the Egyptian indigo." "But what has happened in Northern India has also happened more recently in Madras." "This is all the more remarkable, because in all the older collections, such those of

Wight, Stocks, Law and G. Thomson, *I. sumatrana* was reported only from Malabar and the Konkan, the Coromandel plant being always *I. tinctoria* proper." It is also the form of *I. tinctoria* that was introduced from the East into the West Indies, and is the *I. tinctoria* of Lunan. If, therefore, it be deemed necessary to give this plant a separate name and to remove it from being one of the cultivated states of *I. tinctoria*, Linn., then it will have to be called *I. sumatrana*, Gaertn. In addition to India it also occurs in tropical Africa and Formosa. It may be distinguished from the southern form by its leaflets, which are larger and ovate-oblong or oblong, instead of obovate or suborbicular. The pods are also (in *I. sumatrana*) shorter, thicker, and blunter at the apex, and are usually more numerous and straighter than in the Madras form (Duthie, *l.c.* 255). Leake has devoted much careful study to the cultivated races of this plant in relation to temperature and rainfall. His conclusions regarding the seed supply will richly repay careful perusal.

Tropical Africa.

(8) *var. brachycarpa*, DC. This form has been sent from Guatemala, Central America, Peru, etc. It is apparently not met with in India. America.

Other Indigo-yielding Plants.—The Indigo of modern commerce is thus obtained from one or other of the species of *Indigofera* discussed above. But species of *Indigofera* are distributed throughout the tropical regions of the globe (both in the Old and New Worlds) with Africa as their headquarters. And in addition to the *Indigoferas* several widely different plants yield the self-same substance chemically. Hence, for many ages, the dye prepared from these has borne a synonymous name in most tongues, and to such an extent has this been the case that it is impossible to say for certain whether the *nîlá* of the classic authors of India denoted the self-same plant which yields the dye of that name in modern commerce. The word *nîlá* simply means dark-blue colour, and is practically synonymous with *kála* (black). It is often used adjectivally, such as in *nîlgao* (the blue bull), *nîlopala* (the blue stone or lapis-lazuli), *nîlamani* (the sapphire) and *nîlufar* (the blue water-lily). *Nîla* carries, too, the abstract "darkness," and only becomes a substantive to denote the dye-yielding species of *Indigofera* at a comparatively recent date. *Anil* comes from the Arabic *al-nîl* through the Portuguese, and should have been written *annîl*. History.

Nîlá.

Anil.

The woad of the early European authors (*Isatis tinctoria*) is grown to-day in Centra Asia and has been so for ages past—a region where no species of *Indigofera* has been known to be grown (or possibly could be grown) as a source of indigo. The Sanskrit people may accordingly have first made acquaintance with the indigo of *Indigofera* in India itself, and it is just possible that their *nîlá* may have originally been the woad, which with the ancient Britons was used, like the indigo of the American Indians, to dye the skin and hair. Complex and difficult though the art of dyeing with Indigo may be, it is thus more intimately associated with the early human race than any other known dye or pigment. And in India it would appear that a far larger number of plants are regularly resorted to as sources of this dye than is the case with almost any other country in the world. In addition to *Isatis* met with on the north-west alpine tracts and Afghanistan, mention has, for example, to be made of the *rum* of Assam and Central China (*Strobilanthes flaccidifolius*, p. 1051); of the *ryom* (*Marsdenia tinctoria*, p. 774), found in the north-eastern tracts, a plant closely allied to the original indigo plant of Java; of an indigo plant (*Tephrosia purpurea*) well known in Bombay and Rajputana and closely allied to one of the indigo of the Niger and Egypt; of the *Nerium* or *pala* indigoes (*Wrightia tinctoria*, Woad.

Various Indigoes.

p. 1131) of South India, the plant which would appear to have been used prior to the introduction of the species of *Indigofera*; of the indigoes of Burma (such as *Gymnema tingens*); of Cochin-China (*Spilanthes tinctoria*); and of North China and Siberia (*Polygonum tinctorium*). These and many others are plants which have been, or are being, used as sources of this particular dye in some parts of India. Is it to be wondered at, therefore, that the early records of the industry leave on the mind of the student the suspicion that the plant used in early times was, in all probability, not always the indigo of to-day? Not only has the modern industry shifted from Agra and Gujarat to Bengal, but the plant grown has been changed completely. [Cf. Joret, *Les Pl. dans L'Antiq.*, etc., 1904, ii., 271, 345-6.]

Area Shifted.

It may serve a useful purpose to quote in some detail and in sequence of date a few of the more instructive accounts of the indigo industry of India. It is thus contemplated to concentrate attention on the Indian issues, and if possible to exemplify from past historic records and scientific experience the directions of possible economy and improvement.

Cultivation in
Bombay.

Historic Records of Indigo.—*Periplus of the Erythrean Sea* (80 A.D.) (McCrindle, transl., 17, 109) speaks of indigo as exported from Barbarikon, a Skythian town on the Indus and the port for the metropolis—Minnagar. Marco Polo (1298) gives a grotesque, though accurate, account of the Native indigo industry as seen by him at Coilum (Quilon). "It is made of a certain herb which is gathered, and (after the roots have been removed) is put into great vessels upon which they pour water and then leave it till the whole of the plant is decomposed. They then put this liquid in the sun, which is tremendously hot there, so that it boils and coagulates, and becomes such as we see it. (They then divide it into pieces of four ounces each, and in that form it is exported to our parts)." Athanasius Nikitin (1468) (a Russian traveller) speaks of Kanbat (Cambay) where the indigo grows. Vasco da Gama (1498), Varthema (1503), and Barbosa (1516), who all visited Gujarat and the west coast of Bombay, make no mention of indigo, from which circumstance it may be inferred to have been a comparatively unimportant industry. Garcia de Orta (1563), however, gives a short account of its cultivation and manufacture in Western India. He calls it the *Anil* of the Arabs and Turks, the *gālī* and *nīl* of Gujarat, and remarks that it is tested for purity by burning, when there should be no sand in the residue, and by being so light that it may float on water. Acosta (*Tract. de las Drogas*, 1578, 406) describes the *Anil* of Gujarat. Barrett (1584) mentions indigo from Zindi and Cambaia. It is not apparently referred to in Baber's *Memoirs*, 1519-25, and is but mentioned in the *Ain-i-Akbari*, 1590 (Gladwin, transl., ii., 28, 41), as produced at Agra. Linschoten (*Voy. E. Ind.*, 1598, i., 61-2; ii., 91) speaks of "*Annil*" or indigo as it "groweth only in Cambaia and is there prepared and made ready, and from thence carried throughout the whole world." So again, he says, "*Annil* or indigo by the Guserates is called *gālī*, by others *nīl*: it is a costly colour and much caryed and trafiqued into Portingall: it groweth in India in the kingdom of Cambaia: the hearbe is very like rosemary, and is sowed like other hearbes, and when the season serveth is pulled and dried and then made wette and beaten, and so certain dayes after dried againe and then prepared." (In passing it may be here pointed out that the passage just quoted implies that at the time Linschoten wrote, the dry-leaf process was pursued in Gujarat.)

Indication of
Indigofera.

François Pyrard (*Voy. E. Ind.* (ed. Haki. Soc.), 1601-10, ii., 359, etc.) repeats the account given by Linschoten. In *The First Letter Book of the East India Company*, 1605-6, Birdwood and Foster quote a letter of instructions to purchase Indico of Lahar (Lahore), Serchis (Sarkhej, 5 miles S.W. of Ahmedabad) and Belondri (? Ballabi, a village 20 miles from Bhavanagar). Finch (*Travels in India, in Purchas' Pilgrimes*, 1607, i., 429) affords the first definite conception of the indigo industry of India, or rather of Agra and Fatehpur Sikri, and from him perhaps dates the conception of the plant being an *Indigofera*:—"The herb *Nīl*, groweth in form not much unlike Cives or Cich-pease, having a small leafe like that of *Sena*, but shorter and broader, and set on a very short

Finch's
Account.

foot-stalke, the branches hard and of a woodie substance like unto broome. It usually groweth not above a yard high, and with a stalke at the biggest (which is at the third yeare) not much exceeding a man's thumbe. The seed is included in a small round codde about an inch long, resembling *Fœnigræcum*, save that it is more blunt at both ends, as if it had been cut off with a knife. It carryeth a small flower like that of Heart's-ease, the seed is ripe in November, and then gathered. The herb once sowne dureth three years, being cut every year in August and September after the raines. That of one yeere is tender and thereof is made *Notee*, which is a weighty reddish *Nil* sinking in water, not come to his perfection : that of the second yeere is rich, and called *Cyeree*, very light and of a perfect violet colour, swimming on the water : in the third yeere the herb is declining and this *Nil* is called *Catteld*, being a weightie blackish *Nil*, the worst of the three. This herbe being cut the month aforesaid, is cast into a long cistern, where it is pressed down with many stones, and then filled with water till it be covered, which so remaineth for certain dayes, till the substance of the herbe be gone into the water. Then they let the water forth into another round cistern in the midst of which is another small cistern or center : this water being thus drawn forth, they labour with great staves, like batter or white starch, and then let it settle, scumming off the clear water on the toppe : then labouring it afresh, and let it settle again, drawing forth the clear water, doing this oft, till nothing but a thick substance remaine : which they take forth and spread on cloth, to dry in the sunne : and being a little hardened, they take it in their hands and making small balls, lay them on the sand to dry (for any other thing would drink up the colour), this is the cause of the sandy foot. So if rain fall, it loseth his colour and glosse and is called *Aliad*. Some deceitfully will take of the herbe of all three crops, and steepe them altogether, hard to be discerned, very knavishly. Four things are required in *Nil* : a pure graine, a violet colour, his glosse in the Sunne, and that it be dry and light, so that swimming in the water, or burning in the fire, it cast forth a pure light violet vapour, leaving a few ashes."

Grows for Three Years.

Beating the Liquid.

Balls dried in the Sun.

Sir Thomas Roe (*Embassy to the Court of the Great Mogul*, 1616, i., 270) speaks of the rise in price of Agra indigo and of the sales being effected under *churls* (or fardles). The *churl* of Biana indigo has been computed as being equal to six maunds. Of the same year, Foster (*E.I.C. Letters*, iv., 241) records the following curious passage:—"Indigo is made thus. In the prime June they sow it, which the rains bring up about the prime September : this they cut and it is called *Newty*, and is a good sort. Next year it sprouts again in the prime August, which they cut and is the best indigo, called *Jerry*. Two months after it sprouts again, which they cut and thereof they make the worst sort ; and afterwards they let it grow to seed and sow again. Being cut, they steep it 24 hours in a cistern of water ; then they draw it into another cistern, where men beat it six hours forcibly with their hands till it become blue, mixing therewith a little oil ; then, having stood another day, they draw off the water and there resteth settled at the bottom pure indigo (which some to falsify mix with dirt and sand) ; which they dry by degrees, first in cloths till the water be sunk from it and it be curdled ; afterwards they dry it in round gobbets."

Roe's Account.

Oil mixed with Indigo.

Here we have a distinct reference to the indigo plant having been grown for two or three years without being uprooted or re-sown. H. A. Bailey of Etawah describes the system that exists to-day in Shahabad, which in some respects resembles the old method (*E.I.C., l.c. iv., 356*). This system has long since been abandoned in the indigo districts proper, the change possibly denoting new stock, when that system was unnecessary. The "*Newty*" crop is doubtless the "*Notee*" of Finch, both words being probably derived from *naudhá* (the young plant); and "*Jerry*" being the "*Cyeree*" of Finch, both words doubtless being derived from *jar*, which would mean "sprouting from the root" (*jar*). With the change in the system of cultivation both these terms have become disused and forgotten. Mandelslo (*Travels*, in Olearius, *Hist. Muscovy, etc.*, 1638, 83-4) gives a most curious account of the cultivation and manufacture of indigo in Gujarat (Ahmedabad) which (as with Linschoten's account above) involves acceptance of belief that the method of manufacture pursued was that known as the Dry-leaf. His description of the flower being like that of a thistle was either a mistake (the plant being confused by Mandelslo with *Carthamus*) or the plant used at that time was not *Indigofera*. The former seems the more plausible explanation. The passage may be usefully quoted in full:—"The best indico in the world comes from about Amadabath from a village called Chirchees, whence it derives the name. The herb of which they make it is like that of yellow Parsnip, but shorter, and more

"*Newty*" and "*Jerry*" Crops.

Dry-leaf.

Mandelslo's Account.

bitter, sprouting forth into branches like a Reed, and growing in kind years, six or seven foot high : the Flower is like that of a thistle, and the seed like that of *Fenu-greek*. It is sown in June and cut in November and December. It is sown but once in three years, and the first year the leaves are cut off within a foot of the ground. The stalks are taken away, and the leaves are set adrying in the Sun, and that done, they are set asoaking, for four or five dayes, in a stone-trough, containing about six or seven foot water, which is ever and anon stirred, till such time as the water hath suckt out the colour and virtue of the herb. That done, they let out the water into another trough, where they suffer it to settle for one night. The next day, all the water is taken away, and what is left in the bottom of the trough is strained through a coarse cloath, and is set adrying in the Sun. And this is the best Indico ; but the country people adulterate it, by mixing therewith a certain earth of the same colour. And whereas the goodness of this Drug is discovered by its lightness, they have the cunning to put a little Oyle into it, to make it swim upon the water."

Adulteration.

Mixed with Oil.

Rotation.

"The second year, the stalk which was left the year before shoots forth other leaves, but they are not so good as those of the first. Yet is this preferred before *Gyngey*, that is, wild Indico. It is also the second year that they suffer some part of it to grow up to seed. That of the third year is not good, and consequently not sought after by foreign Merchants, but is employed by the inhabitants of the country in the dyeing of their Cloaths. The best Indico is almost of a violet colour, and hath somewhat of its smell, when burned. The *Indosthans* call it *Anil* ; and after it hath been in the ground three years, they suffer the Land to lye fallow for one year ere they sow it again."

Terry's Account.

Terry says of Gujarat in 1622, "The indico we bring thence is good, and a rich commodity. It is there made of leaves not bigger than those of our Gooseberry bushes, and the shrubs that bear those leaves are about their bigness. These leaves they slip off from the small branches of those bushes, which grow with round and full heads without prickles. The leaves thus stripped off,

Built Vats.

are laid in great heaps together certain days till they have been in a hot sweat ; then are they removed and put into very great and deep Vessels fill'd with sufficient quantity of water to steep them in, where they leave their blue tincture with their substance ; this done, the water is drained out into other exceedingly broad, but very shallow Vessels or Vats, made of Plaister (like to that we call Plaister of Paris) which will keep in all the Liquor till the hot Sun in short time extracts the moisture from it ; and then what remains in the bottome, is a Cream about one quarter of an inch thick, which suddenly becomes hard and dry, and that is our *Indico*, the best sort whereof comes from *Biana*, near unto *Agra*, and a coarser sort is made at *Cirkeese*, not far from *Amadamaz* ; about which two places, are a very great number of those shrubs planted, which bear those leaves." Could the plant have been *Indigofera* ? The passage is taken from *Petro Della Valle (Travels (ed. Hakl. Soc.), 1665, 367)*. Francis Bernier (*Travels, 1656, 283*)

Tavernier's Account.

makes mention of the *Anil* or *Indico* of Delhi. Tavernier (*Travels, 1670 (ed. Ball), ii., 8-12*) of all the early European authors gives perhaps the most detailed and accurate account. He discusses the production in Gujarat (Sharkej, Ahmedabad, Surat, and Broach), of Golconda, of Agra (Biana, Indoua and Corsa) and of Bengal. He then adds that the Dutch Company convey the Bengal dye to Masulipatam, and that the Bengal and Gujarat indigos can be purchased at 30 per cent. less than that of Agra. The reference to a Bengal indigo at the date in question is certainly remarkable. His account is too lengthy for quotation, but it will richly repay perusal. He describes the steeping vats, the use of oil, and the drying in the sun discussed by other travellers. Hove (*Tours in Gujerat, etc., 1787, 107-8*) gives full particulars of several plantations visited by him. The plant, he says, was usually sown in the beginning of the rains and suffered to grow for two seasons. The first crop is cut at the end of the rains and the last about March or April. So late as 1820 we read of indigo planting having existed in Gujarat, and a number of unused pits near old villages and among the buried cities of the Satpuda mountains bear silent testimony to the former important industry of indigo manufacture. Rheede (*Hort. Mal., 1678, i., 101-2, t. 54 ; ix., t. 30*) gives a brief account of the indigo industry of the Malabar coast and furnishes two pictures, which thus leave no doubt that the plant or plants to which he alludes were species of *Indigofera*. Sir W. Hedges, during his agency of Bengal, wrote a diary, 1681, which deals with his tours of inspection through Hughli, Malda, Dacca, Balasore, etc., and discusses the

Bengal Indigo.

Hove's Account

Rheede's Account.

articles of merchandise there met with. It is noteworthy that he makes no mention of Indigo. We are thus led to believe the cultivation and manufacture of indigo, which in time became one of the most important of Bengal industries, could not have existed in the districts visited by Hedges. But we learn it was established in Tirthut originally by the Dutch, for we read of their having owned the Singia concern in 1791. It would seem, however, from Tavernier's allusion to Bengal indigo that a Native industry had existed a little earlier. But shortly after Hedges' report a change was effected, owing to a Resolution of the Directors of the East India Company. European planters were brought from the West Indies to Bengal to undertake the cultivation of indigo. In 1790 indigo factories were accordingly established in Jessore. Hardly, however, had the industry been thus organised when it was ruined, for we read in Sir W. W. Hunter's *Imperial Gazetteer of India* that "English indigo planters have forsaken the districts of Hughli, the 24-Parganas, Dacca Fairdpur, Rangpur, and Pabna, now dotted with the sites of ruined old factories." The industry had thus been established and ruined in Bengal.

It is perhaps hardly necessary to continue this series of quotations much further by supplying a correspondingly detailed selection regarding Africa, Egypt, the West Indies, America, etc. The following may, however, be of value to persons interested in the history of indigo manufacture:—

Rochefort (*Hist. Nat. et Mor. des Isles Antilles*, 1658, 98) speaks of the indigo being produced from a plant which rises only about a foot and a half from the ground. It has small leaves of a light green colour which turn yellow. The flower is reddish. It grows from seed. Its odour is very disagreeable, unlike the Madagascar species, which has small flowers of a whitish-purple colour and a pleasant smell. Pomet (*Hist. Gen. des Drog.*, 1694, 151-6; also Engl. ed. with annot. from Lemert and Tournefort, 1712, 89-91) gives a brief description and an engraving of the plant, and these leave no doubt that it was an *Indigofera*. It is sown, he tells us, by the Americans in holes a foot distant, and in two months' time the plant will be ready to cut, and if left for three months will yield both flower and seed. "Indigo is a meal or flour," he observes, "made by means of water and oil-olive out of the leaves of the *amil* or indigo plant; for there is a difference betwixt that made of the leaves and of the small branches. The choicest of the former sort is that which bears the surname of Serquisse (*Sarkhej*)."¹ "They cut the said herb with a sickle when the leaves begin to fall upon touching them; and after they have stript them from the branches, they put them into sufficient quantity of water, which is in a vessel called the steeping Vat, then letting them infuse thirty-six hours; after which they turn the cock in order to let the water run off, which is tinged of a green colour, inclining toward blue, into a vessel of the nature of a churn, which is worked by the labour of several men, by means of a Rouller or Turner of Wood; the ends of which run pointed, and are hooped with iron; this they work "till the said water abounds with a lather, then they cast into it a little oil-olive; to wit, one Pound into such a Quantity of the Liquor as will yield seventy pounds of indigo, which is the quantity now sold in a b rel; and as soon as the said oil is thrown in, the Lather separates into two parts so that you may observe a Quantity curdled as milk is when ready to break; they then cease churning and let it stand to settle, which when it has done some time, they open the Pipe or Cock of the Churn, in order to let the water clear off, that the meal which is subsided may remain behind at the Bottom of the Vessel like clay or Lees of Wine. Having decanted it thus, they put it into straining Bags of Linnen to separate what water was left, then they convey it to the Chests or Boxes that are shallow to dry it, and being dried, it is what we call Indigo." Pomet furnishes (plate 35) an admirable picture of an indigo factory which shows the water tank, the steeping vat, beating vat and evaporating vat. The mechanical contrivance for churning or beating the liquid is also shown, but the author makes no reference in the text to his plate, and it would appear accordingly to have been copied from some still earlier author. Père Labat (*Voy. aux Isles de L'Amerique*, 1724, i., 90-9, t. 90) gives a long and interesting account of the indigo industry which was translated into English by Philip Miller and given in his *Gardener's Dictionary* (1st ed., 1731) under the name *Amil*, from the belief, apparently, that it was fully representative of the industry as a whole. But Labat deals very nearly exclusively with the indigo of Martinique, and his description, like that of Pomet, is more characteristic of the Antilles and the West Indies than of India proper. In two months' time, says Labat, the first crop of cuttings can be taken, and if the rain continues, sub quent

cuttings may be made every six weeks, and the plants continue to bear for two years.

Browne (*Hist. Jam.*, 1789, 302-5) describes two forms—the wild indigo and the Guatimala indigo. He views the wild as only the survival of a still earlier cultivation, the buildings of which often “remain very perfect to this day.” Browne gives interesting particulars of the “best engine” seen by him for beating; this was in design much the same as some of the contrivances patented in India a century later. He is one of the first authors to mention the use of heat in drying the indigo. “The Magma or mud” is by some put into a cauldron and heated over a gentle fire, but not so far as to boil, and is then emptied into little “ozenbrick” bags to drain; by others it is not heated, but immediately put into the like bags to drain. Edwards (*Hist. British West Ind.*, 1793, ii., 280-8) speaks of three species of indigo, viz. the wild, the Guatimala, and the French. Of these the “French surpasses the Guatimala in quantity but yields to it in fineness of grain and beauty of colour.” Lunan (*Hort. Jam.*, 1814, i., 419-26) gives a most instructive account both of the plant grown and the method of manufacture pursued in Jamaica, but quotes very largely from both Browne and Edwards. The plants are regularly laid in the steeper with the stalks upwards, which, he says, hastens the fermentation. None of these West Indian writers, let it be specially noted, speak of the dry-leaf process—the whole plant is carried at once to the steeping vats. After being beaten by various contrivances a little clear lime-water is gradually let in to augment and precipitate the *fecula*. Too large a quantity of lime would render the indigo hard and of a greyish colour. The *fecula* is placed in bags and allowed to drain; these are then placed within a press and the remainder of the water squeezed out. The dye is next removed from the bags, placed on a table, cut into square cakes and dried in the shade—the sun being regarded as hurtful.

The East India Company published in 1836 a series of reports and letters regarding the indigo industry, the preface to which records (what may have been inferred from the above series of quotations) the migration from and return again to India of the industry. That work will be found of the greatest possible interest, and should be consulted for historic details. Mr. Minden Wilson has written in the *Indian Planters' Gazette* a series of graphic historic sketches of the introduction of Indigo in Bihar. From these it would appear that Mr. Grand, the husband of the lady who subsequently married Prince Talleyrand, was one of the founders of the industry. Wilson gives the dates of several concern—Contai was opened out about 1778 and Singia in 1791; but the last mentioned, as already stated, originally belonged to the Dutch East India Company. These are representative, the Tirhut industry having been mainly established between 1778 and 1800. The Court of Directors of the East India Company sustained severe losses, however, by their endeavours to re-establish the Indian industry, though they obtained the satisfaction of knowing that they had been successful. In time they accordingly threw the traffic open to all, and hoped that their servants might find in indigo “a mode of remitting their fortunes to Europe which would be legal, advantageous and adequate.” For twenty-two years (from 1780 to 1802) the Company directly supported the indigo industry and placed India once more in the foremost rank among the indigo-producing countries of the world. They, however, continued to make purchases of indigo for the purpose of remittances, and to ensure the supply they even made advances to the special factories that had contracted to sell their produce to the Company. About this time also it was recognised that the industry could not be regarded as successfully established in Bengal so long as it was exclusively held by the Anglo-Indian community. It was accordingly arranged that purchases should be made from, and advances given to, factories owned by Natives provided the security was “sufficiently respectable and the quality fit for the European market.”

But the story of the indigo industry is more entertaining historically and more pathetically instructive than that of almost any other Indian agricultural or industrial substance. The main facts may, therefore, be here briefly recapitulated:—There is abundant evidence in support of the belief that when Europeans first began to purchase and export the dye from India, it was procured from the Western presidency and shipped for the most part from Surat. It was carried by the Portuguese to Lisbon and sold by them to the dyers of Holland. It was the desire to secure a more certain supply of dye-stuff that led to the formation, in 1631, of the Dutch East India Company, and shortly after to the overthrow of the Portuguese supremacy in the East. The success of the Dutch merchants

aroused the jealousy of Europe. The woad growers and merchants of Germany, France and England were threatened with ruin, and to protect them nearly every country passed edicts rendering the importation or use of indigo a criminal offence punishable by death.

In 1608 England learned the art of indigo-dyeing, and in the reign of Queen Elizabeth its use was permitted along with woad. Curiously enough this mixing of woad with indigo survives to the present day, and to meet this demand a small amount of the woad is grown here and there over Europe, and even in England. The opposition to indigo was, however, so strong that it was again, on the pretext of being poisonous, prohibited, and in 1660 Charles II. had to procure dyers from Belgium to once more teach the English the art of using the dye. As already shown, the effect of the persistent export of the dye from India, conducted by the East India Company, had the effect of stimulating the Spanish, French, Portuguese and English colonists to make strenuous efforts to produce the dye in many countries outside India. And so successful were they that for a time they ruined the ancient Indian traffic. But Macpherson (*Hist. Europ. Comm. Ind.*, 1812, 200) speaks of the East India Company having voluntarily given up the importation of indigo into England "in order to avoid a competition with the British Colonists in the West Indies and the southern provinces of North America. About the year 1747 most of the planters in the West Indies, particularly in Jamaica, gave up the cultivation of indigo in consequence of the high duty imposed upon it"; "the planters of Carolina and Georgia were never able to bring their indigo to a quality equal to that of Guatemala or St. Domingo." But political difficulties occurred with America and France, and at the same time sugar and coffee had proved even more profitable in the West Indies than indigo. The impetus was thus given for a re-establishment of the Indian traffic, and, as one of the many surprises of the industry, the province of Bengal was selected for this revival. It had no sooner been organised, however, than troubles next arose in Bengal itself through misunderstandings between the planters, their cultivators, and the Government, which may be said to have culminated in Lord Macaulay's famous *Memorandum* of 1837. This led to another migration of the industry from Lower and Eastern Bengal to Tirhut and the United Provinces. Here the troubles of the industry did not end, for, just as indigo had ruined "the Waid Herrn," so the researches of the chemical laboratories of Germany threatened the very existence of any natural vegetable dye. They first killed the madder dye of Europe, then the safflower, the lac and the *al* dyes of India, and are now advancing rapidly with synthetic indigo, intent on the complete annihilation of the natural dye. Opinions differ on many aspects of the present vicissitude; meantime the exports from India have seriously declined, and salvation admittedly lies in the path of cheaper production both in cultivation and manufacture. These issues are being vigorously faced and some progress has been accomplished, but the future of the industry can scarcely help being described as of great uncertainty. The issue is not the advantage of new regulations of land tenure, but one exclusively of natural *versus* synthetic indigo.

IMPROVEMENT OF STOCK.—Sir Edward Law (formerly Finance Minister of India), in a letter to *The Pioneer* in December 1905, refers to his views regarding the future of the indigo industry:—"It would appear to be assumed," he says, "that because unfortunately the production of indigo continues to fall off, my belief in the possibility of recovery of the industry is a mistaken one. In my last budget speech in March 1904, I enumerated the following improvements as necessary to effect a reduction in the cost price of indigo and thereby secure a profit to growers and manufacturers:—(1) that the plantations should be placed on a sound financial basis, and cease to remain in a position where requirements for cash in seasons of dear money could only be satisfied by transferring profits from the pockets of the planters to those of the money-lenders; (2) economy in management; (3) selection of seed and propagation of the qualities yielding the highest percentage of indigotin and best suited to local conditions of climate and soil; (4) rotation of crops to obtain good profits from the land when not under indigo, and thereby reduce the cost of cultivation of the plant; (5) chemical improvements in manufacture." "When

it can be stated that all the improvements I indicated as necessary have been carefully and persistently tried, and that still natural indigo cannot be made to pay, I shall with great regret have to admit that I have been wrong."

Improvement.

There would seem no doubt that each one of the conditions of improvement indicated by Sir Edward are of vital importance; and what is more to the point, hardly any of them have been successfully and completely investigated. A considerable advance would appear to have been attained recently by Bloxam, in his chemical studies of the dye. Leake commenced research into the races of the plant grown and the localisation of the dye within the plant tissue, but his studies were brought to a sudden termination, when on the threshold of possible practical results, through the severance of his connection with the Indigo Planters' Association. It is understood that a start has also been made by the new research station under the direction of the Inspector-General of Agriculture, from which much may indeed be expected in the future. The planters themselves, in their anxiety for alternative crops to be grown on the land when not under indigo, are concerned with an issue of great practical value.

Leake has obligingly furnished for this work a review of his own results and those of other workers in the path of indigo-plant improvement, the passages from which will be indicated by quotation marks.

Present Position.

Present Position of the Industry.—"It may be affirmed that the methods employed for the production of the dye are very crude. The fluctuations in the daily outturn are very large, and all attempts to control the yield have so far proved unavailing, if not prejudicial. This is only one way of confessing our ignorance of the steps of the process. So long as the planting community enjoyed a practical monopoly this inability to control was of little moment. A fall in the quantity of dye produced implied a corresponding rise in price. With the introduction of the synthetic product a short yield no longer meant enhanced price, and this fact, associated with a series of bad seasons, has reduced the margin of profit to a vanishing point. If natural indigo is to compete successfully with its synthetic rival, there is no longer room for the losses which the fluctuations above noticed necessarily involve. A study of the manufacture of indigo reveals how little at present is known of the chemical and bacterial changes involved. Until these have been worked out, little can be hoped for from improvements in the methods pursued. One fact alone is evident, namely that only a fraction of the latent dye-forming power is developed.

Practical Monopoly.

Dye-to Power. g

"For the present, therefore, the planters must look elsewhere to find relief from the severe competition of the synthetic product. The two lines that suggest themselves and which are, to a small extent, receiving attention, are the introduction of supplementary crops and the increase in the yield of plant per acre (cultivation) as opposed to the increase in the yield of dye per unit of plant (manufacture). The first of these falls outside the province of this article. The second falls naturally under two heads (1) improvement of the present plant *I. sumatrana* by seed control, etc.; (2) introduction of other and richer stocks.

"(1) For the same reason that the *mahai* (indigo manufacture) cannot profitably be altered at the present time, it is also impossible to progress in any process of selection of stock, and, as long as it remains impossible

to estimate the dye-yielding capacity of the plant, this must remain so. This, however, does not afford the sole possibility for improvement. The migration of the cultivation of *I. sumatrana* has already been noted. With this migration has arisen a complete separation of the seed-producing districts, and at the present time it is no exaggeration to say that a planter does not know from what district his seed comes. Investigation has shown that the seed-producing area can be separated into two main divisions, each characterised by a very distinct type of plant. The first of these areas includes the Western Panjáb and Indus valley, and the plant here is stunted, flowers early, and possesses a very marked and characteristic alternate arrangement of the branches and leaves. The second area includes the Eastern Panjáb and the United Provinces, in which the plant is tall, bushy, and flowers late. Comparing these :—

Seed-producing
Areas.

	Western Area.	Eastern Area.
Yield of plant per acre	90 maunds	140 maunds
Leaf percentage	62.5 "	54.4 "
Yield of leaf per acre	66 "	82 "

Western and
Eastern.

"Since the leaf is the main dye-yielding part of the plant, it is obvious that large benefits are likely to be derived from a limitation of the seed-producing area.

(2) "For some years attempts have been made to introduce other species of *Indigofera*; and that species which has yielded the most promising results is *I. arrecta*, *Hochst.* It must be borne in mind, however, that Java indigo does not fetch the price of good Bengal indigo, although the percentage of indigotin is very high in the former, and that this may mean a specific inferiority in the dye obtained from *I. arrecta*.

Java *versus*
Bengal.

"A difficulty in obtaining a good germination has alone checked the general cultivation of this plant. The defect has, however, been traced to the large percentage—between 90 and 96—of 'hard' seed. With the introduction of a seed-treating machine this difficulty has been removed and *I. arrecta* will probably be extensively cultivated" (Leake) (see p. 661).

Hard Seed.

The Localisation of the Indigo-producing Substances in Indigo-yielding Plants.—The following is a brief abstract of the contents of the paper on this subject :—"Some attempts have been made to trace the function and place of the indigo-yielding substance in the plant metabolism. For instance, Molisch tentatively ascribes to it a position among the anabolic products, and attempts to establish a direct relation between its formation and the chloroplasts. His arguments are largely based upon the localisation of indigo when precipitated within the tissues. He traces a relationship between the chloroplasts and the grains of indigo thus precipitated. This relationship is difficult to uphold, as the present writer has endeavoured to show. The substance may be found in such tissues as pith, xylem-parenchyma, phloem, fibrous cortical tissue, epidermis and in embryonic tissue, even in the embryo sac. In chlorophyll-bearing tissues, it is difficult to trace any relationship between the chloroplasts and the precipitated grains of indigo. By this method of localisation it is impossible to bring conclusive evidence to prove the absence of a relation between the indigo-yielding substance and the chloroplasts. To establish such a relation other lines of investigation will have to be resorted to" (L ke).

CULTIVATION.

Cultiva-
tion.
Occupation of
Soil.

Soil
Improvement.

Area and
Yield.

Area and Production.—Perhaps one of the most surprising features of indigo cultivation is the variation of the period of occupation of the soil. In some localities the crop is obtained in three months from time of sowing, and from this as a minimum up to as much as eighteen months every possible period is manifested. Speaking generally it may be said that the system of taking several cuttings a year and allowing the plant to occupy the soil for two or even three years seems to have been discontinued—possibly as a consequence of the change that has taken place in the stock now chiefly grown. In the upper provinces, especially where irrigation prevails, indigo occupies the soil in annual rotation with wheat or rice, and is regarded as a catch crop that greatly improves the soil. So much is this the case that indigo has often been recommended as a green manure to be grown temporarily and ploughed into the soil. But in Lower Bengal, on the other hand, the spring-sown crop calls for attention at the very time of the principal rice sowings, and it is therefore an unpopular crop with many cultivators. But a far more serious difficulty has arisen in the production of artificial indigo. The seriousness of this aspect may be at once exemplified by the figures of area and yield. In 1892-3 the area in all India was 1,218,766 acres and the yield 179,056 cwt.; in 1894-5 the corresponding figures were 1,688,042 acres and 237,494 cwt.; in 1896-7, 1,608,901 acres and 168,673 cwt.; in 1898-9, 1,010,318 acres and 139,320 cwt.; in 1900-1, 990,375 acres and 148,029 cwt.; in 1902-3, 645,511 acres and 79,207 cwt.; in 1904-5 the area was 473,757 acres and the outturn 56,200 cwt. Thus in twelve years the area under the crop and the yield decreased to one-third their former magnitude. The most recent forecasts indicate that the area decreased still further in 1905-6, viz. to 583,600 acres with a yield of 46,500 cwt., but the estimated area for 1906-7, namely 452,800 acres, has shown a slight improvement in yield of dye—69,700 cwt.

Land Tenure.—"It is impossible, in the space at disposal, to do more than touch upon the system of land tenure. There are commonly three systems throughout the indigo district of Bihar at present under European control. In the first of these the planter is the absolute possessor of the land, known as *zerat* lands. In the second, as the result of the lease by the *zamindars* to the planters of certain villages, the factory claims some portion—usually two to three *cottas* per *bigha*—of the highlands for the cultivation of indigo. The portion assigned for indigo is usually changed every two or three years. In both these cases the cultivation is effected by labour hired by the factory. In the third, the *raiyat*, under no compulsion, puts a portion of his land into indigo and sells to the factory the plant—either on a valuation of the standing crop or measurement of the amount cut.

"The area in which the cultivation of indigo reaches the highest development is Northern Bihar, the chief districts of which are Champaran, Muzaffarpur, Darbhanga and Saran. In these districts the concerns are entirely under European management. In other areas the specialisation in the methods of cultivation and manufacture is not carried to the same extent. It will be sufficient, therefore, to refer in detail to this area alone, and in the case of other areas to draw attention merely to the points of divergence" (Leake).

BENGAL.—Area and Production.—In 1904–5 the total area under the crop, according to the *Agricultural Statistics*, amounted to 223,100 acres, and the outturn to 24,300 cwt. Cultivation reaches its highest development in Northern Bihar, the chief districts of which are Champaran, which in 1904–5 had 84,000 acres; Muzaffarpur, 35,000 acres; Darbhanga, 32,900 acres; and Saran, 18,000 acres. The final forecast for Bengal in 1906 estimates the total area as 137,800 acres and the yield as 1,323,400 lb. (11,816 cwt.). By way of contrast it may be added that the area devoted to the crop in Bengal during 1894–5 was 629,100 acres, which yielded 104,485 cwt. of dye.

D.E.P.,
iv., 400–
engal.

Areas.

Bihar.—"As cultivation is at present practised, indigo forms a '16-anna' crop. Preparation of the land commences at the end of the rains early in October, as soon as the land is cleared of the previous crop. It is thoroughly ploughed and finally levelled by the application of the *choki* or *hanghar*—a log of wood with the lower surface flat or hollowed, drawn by two or four bullocks. Usually the land is again ploughed and levelled or 'compacted' after a few days—a process which may be repeated as many as four times. In the intervals between the ploughing, gangs of coolies with short sticks are sent over the land. These men collect the stumps of the previous crop, weeds and such like matter, thus clearing the land, and at the same time use their short sticks to break down any clods.

Ploughing.

"The whole of this process is aimed at reducing the surface soil to a state of fine division which will admit a further compacting to be readily effected. It is clear, therefore, that the extent to which the land is alternately ploughed and '*choki-ed*' will depend on the nature of the surface soil. In the high, light (*sumbe*) lands a relatively small number of ploughings will be sufficient; while in the low-lying clay (*mattyar*) lands, a greater number will be required before a sufficiently fine texture is obtained. When the soil is reduced to a sufficiently fine state of division, the plough is no longer used and the *choki* is only applied at intervals—two or three times a month until the time of sowing.

"The reasons for the adoption of these somewhat intricate processes will become plain when certain peculiarities of the soil and climate of these districts are explained.

"Indigo is sown at the commencement of the hot weather—late February or early March. Since the end of the previous rains—early October—only an inappreciable amount of rain has fallen, for in these districts the average total rainfall from November to May, inclusive, is under three inches. The planter, therefore, is entirely dependent on the moisture retained by the soil from the previous rains, both for the germination of the seed and for the support of the young plant until the break of the rains in June. It will be readily understood that, with the temperatures and low atmospheric humidity which prevail at the time of sowing, the surface soil would soon lose all moisture unless this be constantly replenished by

S ons.

oil.

a supply from the deeper layers. Throughout the area the soil consists of an extremely fine alluvial deposit which extends down to and below the water-level—20 feet approximately. It is this unusual condition which makes a rapid capillary movement of water possible. Unless, then, the superficial four or five inches which have been disturbed by the plough are compacted to an extent which will allow the capillary rise of water to take place with a degree of rapidity sufficient to keep pace with the evaporation of moisture caused by the sun's heat, germination and subsequent growth of the plant will be impossible. It is to produce the necessary degree of compactness in the superficial soil that the above processes are adopted.

Temperature.

Throughout this period—November to February inclusive—the lands are kept scrupulously 'clean' by constant weeding. Sowing, as already stated, usually commences in late February or early March. The exact date is dependent chiefly on the temperature, and it is the usual custom to wait till a night temperature of 60° is recorded. Once sowing is commenced, it is carried on with the utmost speed possible. Under the most favourable conditions the increasing day temperature will soon deprive the superficial soil of its moisture, and it is necessary—if the plant is to survive—that it shall have developed a sufficient length of root to be no longer dependent on such moisture. The seed is sown by means of drills, each drawn by two bullocks. Briefly, they consist of a trough, containing the seed, into which small wooden wheels dip. When the drill is in motion these rotate and pick up three to four seeds by means of shallow holes cut at regular intervals in their circumference. The seeds are thus carried forward and dropped down a slot, by which they are guided into a shallow furrow formed by a share situated in front of the slot. Each drill has six shares, corresponding to six wheels set at regular intervals, and thus sows six lines. As soon as the seed is sown a light *choki* is passed over the field and the seed is thus brought into intimate contact with the moist soil at a depth of about one inch from the surface.

Drill Sowing.

Seed to Acre.

"At the present time 8, 12 and even 20 seers (40 lb.) are sown per *bigha* (seven-eighths acre). There is no doubt that this is excessive, and it is difficult to understand how the practice has arisen. It is quite possible, with good seed, to obtain a yield in no way inferior to that normally obtained when using only four seers (8 lb.) per *bigha*. During the hot weather, growth is slow, but with the break of the rains this rapidly increases. The commencement of cutting depends to a large extent upon the date at which the rains break, but usually takes place about the middle of June. The low-lying crops are first cut, both because the more abundant moisture has given greater growth and because delay in cutting causes considerable risk of loss from sudden flooding. Two crops are normally obtained except when the plant is growing in the river-bed, where the rise of the river renders only one possible. These two cuttings are known respectively as the *morhun* and *khunti* cuttings. The crop is entirely hand-cut, and the cut plant is loaded into bullock carts and dispatched to the factory with the least delay possible. Immediately after the *morhun* crop is cut the land is ploughed. This, without damaging the crop, renders the surface open and uneven, and subsequent rain is retained in greater abundance. After the second cutting the land is ploughed and sown with a *rabi* crop or prepared, as before, to receive indigo in the following season. On arrival at the factory the carts are weighed, and the weight of plant is obtained approximately by difference."

Season of Cutting.

Two Cuttings.

Lower Bengal.—"The chief crop of indigo in Lower Bengal is obtained from the annually inundated tracts of land. The seed is usually sown broadcast upon the muddy banks left by the retreating water during the early part of October. In the case of the higher lands only is the plough used and the land, to a certain extent, prepared. The crop is cut in the following June and July" (Leake).

In the districts of Bihar south of the Ganges, Patna, Gaya and Shahabad, the system of cultivation is closely allied to that pursued in the United Provinces. The soil is non-retentive of moisture, and the sowings are carried on chiefly during the rainy season in July, August, and September. The early rainy-season sowings are called *asarhi*, and the crop from these is cut in September and October. The later sowings continue to grow throughout the year and are reaped in July and August, when the crop is known as *khunti*, but that name is also applied to the second year's crop from the early sowings.

[Cf. Montgomery Martin, *Hist. E. Ind.*, 1838, ii., 866-9; iii., 248-57; Taylor, *Topog. and Stat. Dacca*, 1840, 132, 135-6; Westland, *Rept. Journ. Ind.*, 1906, i., pt. ii., 170; *Germination of Java Indigo in Bihar*, in *Agri. Journ. Ind.*, 1906, i., pt. iii., 262-3.]

UNITED PROVINCES.—Area and Production.—The area in 1904-5 was 107,516 acres: 98,695 acres in Agra and 8,821 in Oudh. The estimated outturn was 8,000 cwt. These figures show a great contraction on those of the previous year. The chief districts in Agra are ordinarily Aligarh, Azamgarh, Balandshahr, Etah, Cawnpore, Mainpuri; and in Oudh, Fyzabad. The final forecast for 1906-7 shows a still larger reduction to 40,374 acres: viz. 34,809 in Agra and 5,565 in Oudh. This represents a decrease of 75.2 per cent. on the average area of the years 1900-4, and of 83.5 on the average for 1895-1904.

Commenting on these provinces, Leake says, "In the districts forming the west of the United Provinces and the east of the Panjáb, the cultivation of indigo for dye is practically extinct. The plant is, however, still grown to supply seed to Bihar. The seed is sown broadcast after the land has been irrigated and ploughed during March and April, and in those districts where dye is manufactured the plant is ready to be cut in August, but is left in the ground till December if seed is required. The process of dye manufacture, where practised, is essentially similar to that of Bihar." According to Duthie and Fuller (*Field and Garden Crops*, 1882, i., 43-50, t. xii.) it may be sown either in spring or at the commencement of the rains. In the first case it is called *jamowa* or *chaiti*, in the second *asarhi*. *Jamowa* indigo is ready to cut in August, *asarhi* a month later. Land under *jamowa* is as a rule ploughed up immediately the crop is cut; *asarhi* indigo is left in the ground till the following rains, when it springs up again and yields a *khunti* rop. Generally it is sown alone, though occasionally mixed with *juár* (*Sorghum vulgare*) or *arhar* (*Cajanus indicus*), and is surrounded with a border of castor or *san* (hemp). A loam is prepared; but where copious irrigation is possible, much of the cultivation is on the

lightest possible sand. Four ploughings are held advisable, though frequently in canal-irrigated districts the land receives only one. For *jamowa* indigo the ground must be watered before ploughing, while the *asarhi* fields are not ploughed till softened by the rains. The crop must be kept free of weeds, and two weedings at least are required. The cost of cultivating an acre of *jamowa* indigo, to be cut in August and followed by a *rabi* crop, is estimated at Rs. 15-7a.

C. Prov.
and erar.

CENTRAL PROVINCES AND BERAR.—Area and Production.—

Only 110 acres were reported in 1904-5 as under indigo, these being in the districts of Buldana, Hoshangabad, Narsinghpur and Chanda. In Akola the seed is sown about the middle of the rainy season or latter half of July, and the plant is ready for use in October or November, when the flowers begin to form. [*Cf. Sule, Monog. Dyes and Dyeing, Berar*, 1896, 2.]

D.E.P.,
iv., 409-10.
Panjáb.

PANJÁB.—Area and Production.—

The estimated area in 1904-5 was 53,000 acres, and the yield 9,900 cwt. The large interest in seed cultivation accounts apparently for the disproportion of yield to acreage. The most important districts are Multan, Muzaffargarh, Dera Ghazi Khan and Rohtak. The final forecast for 1906-7 estimates the area at 62,300 acres, as against 67,500 in 1904-5. This total is shown to be 19·3 per cent. below the decennial average. The recent effort by the planters themselves to produce specially improved new seed could have had no other consequence than to disturb and possibly curtail the demand for Native seed. The following are the returns of seed production in the Panjáb for the past four years:—1904, 1,673,800 seers; 1905, 1,785,000 seers; 1906, 3,227,600 seers; and 1907, 1,248,900 seers.

Areas.

Seed
Production.

"The easterly districts of the Panjáb should be considered in conjunction with the United Provinces. In the west, however, in Multan, Dera Ghazi Khan and Muzaffargarh, the methods are very primitive, and the market supplied is the purely Native trade across the north-west frontier. The plant is sown on irrigation, and hence the date of sowing depends on that of the opening of the canals—usually during May. By September the crop is ready to be cut, after which the plant may be ploughed up or left for a second, and, sometimes, even a third, year." "Lands subject to river inundation are considered unsuited; in other words, a prejudice exists against over-inundation. The land is prepared during the cold season after the winter rains, and sowing takes place from March 1 to May 15. The field is first flooded and the seeds scattered broadcast on the water. Irrigation is given every third day till the plants are about a foot high, then every eight or ten days" (Leake). [*Cf. Morris, Cult. and Manuf. Indigo in Mooltan, Gaz. Mooltan Dist.*, 1883-4, app. a, 161-6; *Panjáb, Dist. Gaz.*]

ombay.

BOM AY AND SIND.—Area and Production.—

The late Mr. E. C. Ozanne, then Director of Agriculture, Bombay, wrote in his Annual Report (1885-6, 36-7) that—"In the 16th and 17th centuries, indigo, partly of

local growth and partly brought from Upper India, was one of the chief exports of Gujarat. Towards the close of the 18th century (1777) the cultivation, chiefly for local use, would seem to have been on a very considerable scale. But in the early part of the present century it again fell off and in 1827 had almost altogether ceased. At that time, prices were high and the demand was strong." The attempt then made to resuscitate the industry, however, failed, and "indigo has never again become a product of any importance." In an official letter of date 1889, Ozanne, however, speaks of the indigo cultivation of Bombay having been 4,182 acres. In 1904-5 there were only 806 acres under the crop. The following account of the cultivation in Western India is an abbreviation from Mollison (*Textbook Ind. Agri.*, iii., 279-83). The best crops are grown on *gorādu* soil (deep sandy loam). In the Deccan, medium black soils of fair depth are deemed most suitable. The crop is grown in the *khārif* (rainy) season. "Thorough tillage and a liberal application of manure are necessary. Well-rotted manure in a dressing of twenty cart-loads per acre should be given in May. The plough and harrow should be used after the first fall of rain to prepare a clean, smooth seed-bed. The crop is either sown alone or with subordinate rows of cotton. One row of cotton may alternate with two of indigo. When sown alone, the rate is 12 to 15 lb. seed per acre. The seed should be drilled if possible in June in rows 18 inches or less apart and the drill should be worked near the surface, so that the seed is not buried too deeply. The crop should, after the seedlings are well up, be intercultured two or three times with the bullock hoe and be once hand-weeded with the weeding-hook (*khurpa*). The first cut is ready in September-October. With favourable late rain, a second cut may afterwards be obtained without irrigation."

Modern Traffic.

Mixed Crop.

The area in 1904-5 was in Sind 5,621 acres, chiefly located in Hyderabad, 3,985 acres, and Sukkur, 1,404 acres. After the land has been weeded and moistened during the inundation season in May and June, it is ploughed two or three times and the seed sown broadcast. When the plants have germinated, they are watered once a week, and this is continued till September, when the crop is ready to be reaped. A second year's crop is raised after cutting by frequently watering the old plants. [*Cf.* N. B. Beyts, *Gujarat Agri.*, 1878, 44.]

Sind.

MAD AS.—Area and Production.—The area under cultivation in 1904-5 was 126,300 acres, and the outturn 16,700 cwt. The principal districts are ordinarily Cuddapah, which in 1904-5 had 32,149 acres; South Arcot, 28,784; Nellore, 14,618; North Arcot, 7,352; Karnul, 7,056; Anantapur, 5,098; and Kistna, 3,208. The forecast for 1905-6 shows an estimated area of 212,300 acres and an outturn of 1,896 tons. Commenting on this result, the Board of Revenue in their final report for 1906-7 show that this area is 86 per cent. more than in 1905-6, but 1 per cent. less than the average of the five previous years and 25 per cent. less than the ten previous years. Indigo appears to be cultivated under very diverse conditions throughout the Presidency. "Returns show that somewhere in the district sowing is normally being accomplished in every month of the year. This, no doubt, is due to the more even distribution of temperature and rainfall throughout the year" (Leake).

D. P.,
iv., 413-5.
adras.

Chief
Districts.
Forecast.

In Cuddapah, the chief indigo district, the land is ploughed and manured after it has been moistened by rain. This takes place in April if the rain is sufficiently heavy; if not, in July or August. The ground is then allowed

Seasons.

to remain till the next heavy showers, when the seed is sown in rows. In about a month weeding commences. On dry lands the crop is entirely dependent on rainfall. The first cutting is taken three or four months after sowing, and a second and third at intervals of three months after the first. After the third cutting, the plant is allowed to seed.

Wet Cultivation.

Wet cultivation is also carried on in the neighbourhood of tanks or wells. Near wells with a certain supply of water, cultivation is commenced in March or April. If the soil is loose, the seed is sown without any previous ploughing; otherwise, in the vicinity of tanks, the land is watered, ploughed, and smoothed by a roller. It is then manured, watered again, and the seed sown when the land has dried. After germination, the crop is regularly watered at intervals varying from a week to twenty days. Weeding commences a month after sowing, and the first cutting takes place in three or four months, the second three months later. [Cf. Shortt, *Man. Ind. Agri.*, 1885, 98-136; *Mem. on Prog. Madras Pres.*, 1893, 69-71; Cox, *Man. North Arcot Dist.*, 1895, i., 273-4.]

D.E.P.,

Burma.
Areas.

U MA AND ASSAM.—Area and Production.—Indigo is cultivated to a very limited extent in Burma. In 1904-5 there were 424 acres in Upper and 58 in Lower Burma. In Upper Burma cultivation is confined to the districts of Pakokku, Lower and Upper Chindwin and Sagaing, and in Lower Burma to Thayetmyo. The gravest suspicion, however, should be entertained in accepting the published figures of area as being *Indigofera*. The description given by Mr. H. G. A. Leveson, in a note on the dyes of the Southern Shan States, at all events, leaves little or no doubt that much of the indigo of that country is derived from *Strobilanthes*. In Chindwin there are reported to be two crops, the wet- and the dry-weather. The wet-weather crop is sown in June and collected in July and August; the dry is sown in October and collected in December and January. An indigo plant is also said to flourish at high elevations in the Shan States. It is remarked that when cultivated in the lower valleys it is generally under the shade of trees, and when grown on the hills, plots of ground are selected at the bottom of steep valleys. Brackish soil is regarded as the most suitable, and the ground is not manured. It is not grown from seed, but at the beginning of the rains the shrub is cut to the ground, the lower part of the stalk thrown away, and the upper part with the young leaves planted. Two or three pluckings are considered a fair average yield, though a well-grown plant may afford as many as five. Most of these statements, it may be inferred, denote *Strobilanthes*.

Seasons
and Crops.

Different
Species.

Assa .

Turning now to Assam, the cultivation of indigo may be said to be practically non-existent. The greater part of the indigo dye of the province is the produce of *Strobilanthes flaccidifolius*, and not of *Indigofera*. In many respects Assam and Upper Burma show a closer approximation to the conditions of South and Central China than to those of India. Accordingly Assam, in the matter of this particular indigo-yielding plant, may be spoken of as the most western portion of the area of *Strobilanthes flaccidifolius*, a plant that is from there diffused east and north throughout the greater part of China and becomes one of the most important sources of the dye in that vast empire. [Cf. Leveson, *Dyes and Dyeing in Southern Shan States*, 1896, 2-5; Duncan, *Dyes and Dyeing in Assam*, 1896, 28, 29; Parlett, *Rept. Settl. Oper. Sagaing Dist.*, 1903, 15.]

anures.

Manures.—Generally speaking the only manure given in indigo cultiva-

tion is the refuse of the indigo plant termed *seet*, procured from the factory. Artificial manures have made little headway, and even with the simpler fertilisers, such as lime, gypsum and nitre, there is uncertainty as to their efficacy. In this connection attention should be given to the results obtained by Mr. C. Rawson, summarised in his final report to the Bihar Indigo Planters' Association, published in 1904. As a rule indigo soils were found deficient in available phosphoric acid, and responded remuneratively to treatment with superphosphate, bonemeal or other phosphatic manures. Nitrogenous manures were generally found useful when applied along with phosphates. Dr. Hancock, working at Dalsing Serai under Mr. Bernard Coventry in 1901 (*Rept. Indigo Improv. Syndicate*, 1901), arrived at the same conclusions. The value as manure of the refuse plant (*seet*) was also investigated by Rawson, with the result that he came to believe that in many cases it was as valuable as the indigo produced by the factory. Mr. W. Popplewell Bloxam next took up the inquiry into the subject of indigo improvement by scientific manuring. In his report to the Government of Bengal, 1905, on the work carried out by Leake and himself at Dalsing Serai (in 1903-4), he summarises his experiments and results. The chief feature of these may be characterised as the supply of various carbonaceous materials to indigo soils with the view of ascertaining their effect on the growth of the nodule bacteria. The period of Bloxam's experiments was, however, too short to allow of any very definite conclusions. [*Cf. Voelcker, Improv. Ind. Agri.*, 1893, 106, 112, 259, 260-1; *Rept. Cawnpore Exper. Farm*; Bergtheil, *Acc. Sc. Invest. on Indigo*, in *Rept. Dept. Land Rec. and Agri. Beng.*, 1905, vii.-ix.]

Superphosphates.

Carbonaceous
Materials.

Dangers to the Crop.—"Under favourable conditions the young plant will appear above the surface on the seventh to the tenth day, from which time onwards it is exposed to many vicissitudes. It is no uncommon occurrence to find the destruction of the crop to be caused by a shower of rain. It has already been explained that the young plant is dependent on what may be termed 'bottom' moisture for its early growth, and on the condition of the soil which makes this available. The 'compacting' of the surface soil leaves a loose, dry layer on the surface which acts to a certain degree as a check on evaporation. The effect of rain is to do away with this dry layer and to establish a complete capillary system to the absolute surface. The ultimate result is a rapid decrease in the moisture of the superficial soil, which may ultimately be reduced to below the limit at which life can be supported. Under these circumstances the crust must be broken even at the cost of destroying half the crop. This is usually effected by the use of a light rake, or, in the case of a very light crust, by brushwood drawn over the surface. A prolonged spell of hot west winds, such as are common during April-May, in spite of the precautions taken to conserve the moisture, reduces this to below the needful minimum, and in this way the greater part of the crop may be lost."

Dangers.

Effect of
Moisture.

Surface C t.

"As regards pests little can be said. The larvæ of numerous LEPIDOPTERA feed on the indigo plant, but in only one case are the ravages sufficient to cause serious damage. Under favourable conditions the larvæ of *Agrotis segetis* appear shortly after the young plant has broken through the soil, and before what is known as the '7-leaf' stage is reached. Plants attacked will be entirely stripped of their leaves, and a second sowing may be necessary. In bad seasons this may also happen, and necessitate a third sowing. It seems probable that the ravages of this pest are only

Pests.

Grubs.

serious in those lands which have been sown in indigo for several years in succession, and that a reasonable system of rotation would reduce the injury to a negligible quantity."

Aphides.

"Of other insect pests which assume dangerous proportions, there is an *Aphis* and a *Thrips*, but little or nothing is known of the life histories of either. They both attack the young plant, rendering it stunted, and the latter, by destroying the mesophyll of the cotyledons and first foliage leaves, may kill the entire plant" (Leake). [Cf. Lefroy, *Caterpillar Pests of Indigo in Bihar*, in *Agri. Journ. Ind.*, 1906, i., pt. iv., 338-50.]

Yield.

Output and Yield.—"Owing to the numerous variations in the exact area denoted by the term *bigha*, and to the confusion consequent thereon, it is almost, if not quite, impossible to determine with any degree of certainty from the published returns what is a normal yield of plant and dye. Under these circumstances it seems best to give the returns for a particular concern for which the figures are available and which, being situated in the centre of the indigo districts of Bihar, may fairly be taken as normal. The period from which the averages are derived covers a term of eleven years, viz. from 1892-1903. This shows an average of 80 maunds of plants per acre for the *morhun* cutting, and 35 maunds of plants per acre for the *khunti* cutting, while the dye manifests an average of 16 lb. per acre for the year, in the proportion of 11 lb. for the *morhun* and 5 lb. for the *khunti* cutting. The fluctuations are, however, very wide, e.g. for plant per acre 168 to 48 maunds, and for dye, 25 lb. to 7½ lb" (Leake).

Plants to the Acre.

Dye to the Acre.

MANUFACTURE.

anufac-
ture:
Wet
Process.

WET PROCESS.—"For the manufacture of dye from the plant, the wet process is now almost invariably adopted. Briefly this consists in the extraction from the plant of the dye-yielding principle by steeping in water, and the precipitation, from the extract so obtained, of indigo by exposure to air—oxidation. As the amount of plant which must be daily steeped comes to some hundreds of cartloads, there are certain essentials which must be considered in choosing a site for a factory. Chief among these is an abundant supply of water; and a factory will never, therefore, be found at a distance from a stream or large lake, from which water can be pumped into a large tank—*khazanah*—placed at the highest point of the factory. From this tank channels conduct water to the steeping vats, a row of brick and cement-lined basins, usually about 20 feet square and 4 to 5 feet deep, and about 15 in number. Below these, and corresponding with them in number, are a second row of slightly shallower vats called the beating vats.

Site of Factory.
Water Supply.

Steeping Vats.

"The plant, on arrival at the factory, is loaded into the steeping vats and, as soon as each vat is full, is battened down by means of beams attached to pegs set in the sides of the vat. Water is now run in until the plant is just submerged, and steeping is allowed to proceed for a period varying from 12 to 14 hours. The liquor, which has by this time become yellowish green and almost fluorescent, is now run off into the lower, or beating vat.

Beating Vats.

"Beating is effected in various ways, the sole object being to obtain as thorough an oxidation as possible. In the more primitive method 10 to 12 coolies enter the vat and proceed to beat the liquor with short sticks to one end of which flat discs of wood are attached. The process is complete after about 1½ hours' continuous beating. With the introduction

of machinery the hand beating has been to a certain extent replaced by wheel beating. Where this is employed, there is a single beating vat which runs the length of the range of vats and is divided along its length by one or two walls, the number depending on whether one or two beating wheels are employed. These walls stop short of the two ends of the vat and are simply employed to give direction to the circulation set up by the wheels. The wheels themselves consist of small flat discs of wood attached to the ends of a number of spokes radiating from the axle. By this method beating is complete in about one hour. More recently the beating has been replaced by blowing a mixture of air and steam through the liquor; and, later still, in 1902, this process, modified so as to blow ammonia through the liquor, was introduced by Rawson. Neither of these latter processes have, however, been universally adopted, and the wheel beating is still most commonly employed.

"After beating is complete, the liquor is allowed to stand until the precipitated indigo—the *mal*—has settled, leaving a clear, red, supernatant liquor. This '*maila pami*' is drained off and the residual '*mal*' is pumped into boilers where it is mixed with clean water and boiled, either by the direct action of heat or by injecting steam. The boiling and subsequent stages in the manufacture take place within the factory building. When the boiling is complete, the contents of the boilers are run on to the '*table*.' This consists of a heavy canvas sheet which has been previously wetted and spread on a support of split bamboo. The cloth acts as a filter, allowing the clear water to drain off and retaining the indigo as a thick paste which is now transferred to the press. This is a square wooden box, the walls and bottom of which are perforated by numerous holes. The interior is lined with damp cloth and the *mal* is then poured in to a depth of 8 or 9 inches. The lid, which fits the interior accurately, is then put on and screwed home by means of a screw worked by a long lever. This is turned at intervals during 5 to 6 hours, in which time the *mal* will be pressed into a hard cake 3 to 3½ inches thick. The sides of the press are now removed and the cake is transferred to a table where it is cut by wire into cubes of about 3 inches. These are removed and placed on open shelves to dry in an airy room. The air admission is so regulated that slow drying is effected. This is essential if cracking and subsequent breakage of the cakes are to be avoided. During the process of drying, the cake becomes covered with a dense growth of mould. Before packing this is brushed off by coolies. The final stage consists in packing the dried and cleaned cakes into specially constructed cases which are weighed and forwarded to Calcutta for disposal" (Leake).

DRY PROCESS.—The wet method just described by Leake is that which is almost universally employed, though in Madras the dry-leaf process is still pursued to a limited extent. From the historic chapter given above it will be seen, moreover, that during the first century of the industry as fostered by the East India Company, the dry process was apparently universally adopted. It was even upheld that to that fact was attributable the high merit of the Indian as compared with other indiges—the stems and twigs used in the wet vat system detracted, so it was then believed, very greatly from the merit of the dye. During the second century, when the industry had been conveyed from the West Indies back to India, or rather to Bengal, the wet process was alone that employed. It is significant that throughout all this rise and fall of the

THE INDIGO PLANT

European industry in India, the Natives should have quietly continued their own methods of manufacture, oblivious of or indifferent to the numerous patent processes and appliances brought out by their European rivals. By the dry method the bundles of freshly cut plant, instead of being conveyed directly to the factory, are dried and the leaves separated from the stem by beating. When kept dry the leaves turn in the course of a few weeks from green to a blue-grey colour. They are then subjected to steeping and fermentation, when the *indican* present in the plant splits through hydrolysis into *indigotin* and *indigluin*. The fine green liquor thus obtained is then drawn off to the beating vat, where the matured indigo is precipitated and subsequently concentrated by boiling and compressed into cakes and dried in the usual way. But for the adulteration so largely resorted to by the Native manufacturers, it seems fairly certain the dry-system indigo would be fully as valuable as the wet, and in some respects have distinct advantages. This is exemplified by the fact that it is preferred even in localities where the difficulty of drying becomes serious. For a small manufacturer it has the great advantage of being attended to at the most convenient time.

The rationale of indigo manufacture may be briefly and pointedly told. Fermentation and hydrolysis of the *indican* found in the steeping vat takes place. The *indigotin* produced is reduced by the *indigluin* to *hydrindigotin* (indigo white), and this dissolves in the alkaline liquor. Through the beating that follows the *hydrindigotin* is reoxidised, and *indigotin* precipitated—being insoluble in the alkaline liquid. The yield is about 0·2 per cent. of the weight of the plant. The addition of ammonia to the vat is frequently practised, with the result that the yield is largely increased, as the formation of ammonia by the fermentative breaking down of the indigo is thus hindered. The indigo obtained in this manner varies greatly in quality. Its content of *indigotin* ranges from 20 to 90 per cent., the average being 40 to 50 per cent. The remainder consists of ash, 5 to 20 per cent. ; water, 2 to 8 per cent. ; *indirubin*, 2 to 4 per cent., and various amounts of indigo-brown, indigo-gluten, and carbohydrates. The value of the blue depends on its content of *indigotin* and *indirubin*. [Cf. Blount and Bloxam, *Chem. for Engin. and Manuf.*, 320.] It is believed the presence of *indirubin* gives the more pleasing result of the natural as compared with the synthetic dye.

Mr. W. Popplewell Bloxam (who has devoted much attention to the study of the chemistry of indigo) read a highly instructive and valuable paper before the Society of Chemical Industry (Yorkshire Section) on August 15, 1906, and still more recently a further paper before the London Section on November 30, 1907. The last mentioned is written by Bloxam in collaboration with Dr. R. Gaunt and Mr. F. Thomas, and is specially described as an analysis of indigo and of the dried leaves of *I. arrecta* and *I. sumatrana*. It is, therefore, desirable that readers anxious for information of the nature indicated should consult the papers mentioned. But it may be useful to give here the few concluding remarks in the first, since these seem to give an indication of the direction and purport of Bloxam's investigations :—

Analysis of
Indigo.

Purport.

"From these results, it will be seen that if the percentage of indigotin contained in the whole plant (ordinary Indian varieties) be taken, as seems reasonable, at 0·6 per cent., then from consideration of the weights of plant steeped and the indigotin recovered in the finished cake, the highest

efficiency attained does not reach 50 per cent. of the total indigotin obtainable, whilst the average efficiency of the 'mahai' is 25 per cent., falling thence to 12.6 per cent. (cake No. 2). The attention of the Government of India will be called to this wasteful method of manufacture, with a view to the long-needed improvements being introduced to India without delay." Concluding the second paper, Bloxam and his collaborators observe:—"Being now in the possession of some 150 grms. of crystallised indican, we are undertaking a scientific study of its quantitative conversion, by various methods, into indigotin—with the view of improving the process of manufacture at present in use in India. The results of our experiments all tend to show that considerable improvement remains to be made in the efficiency of the indigo manufacture, and point to the fact that the efficiency of the process is far lower than is currently stated." Bloxam submitted his final *Report of the Research Work on Indigo* to the Government of India in 1908.

Improvement of
Manufacture.

[Cf. Buchanan-Hamilton, *Stat. Acc. Dinaj.*, 1833, 307-14; Montgomery Martin, *Hist. E. India*, 1838, ii., 986-96; Reid, *Cult. and Manuf. of Indigo*, 1887, 65-73, 74-86; Nicholls, *Trop. Econ. L'Indo-Chine*, July 1903, n.s., vi.]

SYNTHETIC INDIGO.—It would be impossible to deal here with the discovery and production of synthetic indigo. As a matter of historic interest it may be mentioned that Perkin was (in 1856) the original discoverer of the coal-tar dyes, but, like Green's discoveries still later, they were not fully appreciated until they had reached the Netherlands and German laboratories. Hence for a good many years past the artificial dyes have proved formidable rivals to the natural colours, and even in the case of indigo have begun to curtail the world's demand for the Indian article. Already the exports from India have been reduced very seriously. Germany, for example, has practically ceased to import vegetable indigo, and her exports of the artificial products to all countries were last year valued at 25,000,000 marks (£1,250,020). This is remarkable, seeing that the first commercial manufacture was only made in 1897. According to a report issued by the Badische Anilin and Soda-Fabrik Company, their profits were in 1903, £583,787, and in 1904, £544,936. Thus it would appear probable that large sums have been realised from the sale of artificial indigo. The imports of synthetic indigo are mainly from the Netherlands. These came to 14,691 cwt., valued at £143,613 in 1902; 17,752 cwt. in 1903; 19,458 cwt. in 1904; 32,246 cwt. in 1905; and 39,042 cwt., valued at £147,325 in 1906.

synthetic
Indigo.

Great Britain's
Supply.

T. ADE IN INDIGO.—In a dispatch dated 1792, the Board of Directors congratulated the Indian Government that, as the British imports of Bengal indigo increased, those from the Spanish and French colonies declined, while at the same time a large export trade from Great Britain to the Continent had been established. That re-export trade amounted in 1790 to close on one million pounds of the dye. Such a brilliant result, when contrasted with the depression that has been cast over the industry, within the past few years, is highly significant. But

D. P.,
vi., 4 l-
Trade.

Early
Transactions.

with the detailed statement of former transactions, given in the *Dictionary*, it may suffice to review here, and very briefly, the returns of the past few years :—

Exports. *Exports.*—The bulk of the factory-made indigo is exported. India uses up only the most inferior grades of the dye. The returns of foreign trade thus very nearly express the total production. The year 1894–5 showed the highest production credited to the Indian industry, viz. 237,494 cwt., produced from 1,688,042 acres. Up to that point the prosperity was almost phenomenal—a century of advancement, in spite of numerous local upheavals. But the year following the first commercial production of synthetic indigo the crash came, and from that time there has been nothing but continuous curtailments. From 1894–5 down to 1906–7 the record is, in fact, a very melancholy one. The exports in 1894–5 were 166,308 cwt., valued at Rs. 4,74,59,153, and in 1895–6 they were 187,337 cwt., valued at Rs. 5,35,45,112. But the twelve years following show a continuous decline, until in 1906–7 the exports were only 35,102 cwt., valued at Rs. 70,04,773. Commenting on this subject, J. A. Robertson (*Rev. Trade Ind.*, 1904–5, 28–9), at that time Director-General of Statistics in India, wrote: “The unremunerative level to which prices have been forced down by competition of synthetic indigo has reduced the indigo plantations of Bengal to less than half the area they occupied ten years ago, and over the whole of India the reduction in that period was 66 per cent. Planters in Bengal are strengthening their position by cultivating other crops in addition to indigo, and they can carry on a contest for supremacy with synthetic indigo for many years.” “The season of 1904 gave a very poor yield, the deficiency compared with the previous year being estimated in the official reports at 31 per cent. in Bengal and 45 per cent. for the whole crop. The total exports of 1904–5 are less by 18·4 per cent. in quantity, and 22·4 per cent. in value, than the exports of the previous year. The fall in the average price was thus 4 per cent., and in Calcutta the fall was more marked in the better kinds than in the ordinary qualities.”

Great Britain's share. Turning now to the countries which have drawn on India for their supplies of indigo, Great Britain formerly headed the list. The exports from India to Great Britain in 1875–6 came to 72,494 cwt.; in 1883–6 to 64,204 cwt.; in 1895–6 to 66,215 cwt.; and in 1898–9 (the year after the production of synthetic indigo) they dropped to 30,973 cwt.; since which date they have steadily declined until in 1904–5 they were only 10,743 cwt.; in 1905–6, 7,749 cwt.; and in 1906–7, 7,942 cwt. The record of the United States is somewhat similar, though on a smaller scale. In 1875–6 the share taken by the States came to 4,089 cwt.; ten years later it became 20,737 cwt., and from then a decline has been observed until in 1905–6 the amount taken was only 1,530 cwt., and in 1906–7, 1,258 cwt. Egypt, on the other hand, has preserved a fairly constant market, but it has to be explained that Egypt takes mainly Madras dry-leaf indigo. In 1875–6 it drew 577 cwt.; in 1885–6, 11,601 cwt.; in 1895–6, 13,995 cwt.; in 1903–4, 15,375 cwt.; in 1905–6, 9,702 cwt.; and in 1906–7, 9,195 cwt. With most Continental countries the decline in the demand for Indian indigo has been most marked. Germany took in 1895–6, 16,929 cwt.; in 1903–4, only 1,776 cwt.; in 1905–6, 487 cwt.; and in 1906–7, 523 cwt. France procured in 1895–6, 21,011 cwt.; in 1903–4, 1,975 cwt.; in 1905–6, 970 cwt.; and in 1906–7, 541 cwt. Japan, which for several years had been one of the

chief markets, almost ceased to import in 1904-5. This, it is believed, was largely a consequence of "the differential taxation which took effect from April 1, 1903 and imposed an extra tax, equal to 1.55 pence per lb., on Indian indigo, which both Java plant indigo and German synthetic indigo escaped, placing an insupportable burden on the trade; but now that Indian indigo has been treated on the most-favoured-nation basis by the Convention with Japan, which came into force on March 15, 1905, there may be some revival of the trade. German synthetic indigo has, however, now acquired such a dominant position, and its higher percentage of colouring matter still retains for it such advantage by reason of the duty being charged by weight, that India will find it difficult to recover lost ground" (Robertson, *l.c.* 29). The exports from India to Japan in 1906-7 were 1,800 cwt. [*Cf. Rept. Beng. Chamber of Comm.*, 1903-4, 163-8.]

Internal Trade.—Turning now to the shares taken by the provinces of India. In 1885-6 the total exports were 132,495 cwt., of which the Bengal share was 76,109 and the Madras 45,828. Ten years later (1895-6) the total exports were 187,337, of which the Bengal share was 111,714 and the Madras 62,425 cwt.; in 1903-4, 60,410, of which Bengal furnished 29,858 and Madras 24,414 cwt.; in 1905-6, 31,186, of which Bengal supplied 19,062 and Madras 7,756 cwt.; and in 1906-7, 35,102, of which Bengal contributed 19,309 and Madras 11,159 cwt. The exports across the land frontier are not very important. In 1904-5 they came to 4,873 cwt., valued at Rs. 4,70,203; in 1905-6 to 5,275 cwt., valued at Rs. 5,26,431; and in 1906-7 to 3,518 cwt., valued at Rs. 3,47,341. The most important receiving countries are Seistan and Dir, Swat and Bajaur. Formerly a large trade was done in exporting indigo-dyed goods from India. The only survival of this is the export of blue cloth from Pondicherry to French China—a survival due, apparently, to the French protectionist enactments in favour of her colonies.

Internal Trade.

French Protectionist Enactments.

I ports.—A startling peculiarity of the present phase of the Indian traffic in indigo may be said to exist in the circumstance that a small supply of the dye is annually drawn from the Straits, from the United Kingdom, Belgium and Japan. There is no mention of synthetic indigo being imported, and the small foreign supply may be to some extent returns of Indian indigo. The imports in 1905-6 were 1,244 cwt., valued at Rs. 1,12,243; and in 1906-7, 2,392 cwt. and Rs. 97,152.

Imports.

I CT (I CTA); *Fa. Br. Ind.*; Hampson (Moths), i.-iv., Bingham, *Wasps and Bees* (Hymenoptera), i.-ii.; Distant, *Bugs* (Rhynchota), i.; Watt, *Products Derived from Animal Kingdom* (Insects), 64-5; Maxwell-Lefroy, *Economic Entomology*, in *Journ. Bomb. Nat. Hist. Soc.*, xv., 432-44; also *Locusts in India*, in *Agri. Journ. Ind.*, 1907, ii., pt. iii., 238-45, tt. xiv-xx.

D. P., iv., 470-1. Insects.

With the exception of the silkworms, the bees, the cochineal, the lac and the gall-forming insects, very few others can be regarded as of economic value. Unfortunately a very large number of insects force attention through the depredations they effect on crops, stores of food, industrial materials, manufactures, woodwork, etc. Maxwell-Lefroy has set forth in a lucid manner the difficulties that beset the entomologist in India who may have entrusted to him the investigation and solution of the pests of the fields and forests or the discovery of beneficial insects. The insects have to be identified and in many cases scientifically named, then their life-histories worked out, before practical suggestions are possible. Throughout the present publication the effort has been made to record the results

Economic Value.

Pests.

hitherto attained under the names of the products concerned, such as *Corchorus* (Jute), *Camellia* (Tea), etc. But in addition, the following special articles deal with insect economic products:—

Bees', Bees'-wax, Dammar and Honey (see pp. 123-9).

Coccus Cacti, Cochineal (pp. 347-9).

Silk (pp. 992-1013).

Tachardia Lacca (pp. 1053-6).

Besides these, however, there are a few other insects that have attracted attention. Perhaps the most important is the Locust. This often proves so destructive that strenuous efforts become necessary to restrain it. In order to aid in their identification, Maxwell-Lefroy has recently published an interesting account of the life-histories, with full-page illustrations, of the two locusts known to India, viz. the Bombay Locust and the North-West Locust. [The following papers have appeared in *The Agricultural Ledger*:—Gunther and Cotes, *Dried Locusts as food for Cage and Game Birds*, 1893, No. 2; *The Automatic Locust Catcher*, 1895, No. 15; Stewart Stockman, *A Plague of Grasshoppers in the C. Prov.*, 1903, No. 3, 56-85; Maxwell-Lefroy, *Mem. Dept. Agri. Ind.*, 1906, i., No. 1; 1907, i., 125.] Sly (*Agri. Journ. Ind.*, ii., pt. ii., 208) gives a brief forecast of a report shortly to appear on the results attained in India with the locust parasitic fungus.

The wing-cases of the beetle *Buprestis vittata* are largely employed for ornamental purposes in India, and are especially worked up in articles of dress produced in Madras and Hyderabad, or are used in *khas-khas* fans, etc. [Cf. Mukharji, *Art Manuf. Ind.*, 309, 313, 380; Watt, *Ind. Art at Delhi*, 1903, 161, 198, 408.]

Wild Pot-herb.

I. aquatica, Forsh.; *Rec. Bot. Surv. Ind.*, ii., 121, 185, 243; iii., 81. The *kalmi-sāk*, *nāri*, *ganthian*, *nālchi baji*, *sarkarei valli*, etc. An aquatic species common throughout India but especially abundant on the surface of tanks in Bengal. The young shoots, leaves and roots are universally eaten as a vegetable, and the plant is for that purpose often semi-cultivated. The juice is believed to have emetic properties and to be useful in opium poisoning. [Cf. *Pharmacog. Ind.*, ii., 540; Dutt, *Mat. Med. Hind.*, 1900, 302.]

I. gitata, Linn.; Talbot, *List Trees*, etc., 1902, 251. The *bilāi kand*, *bhui-kohala*, *matta-pal-tiga*, etc. A large climbing perennial cultivated on account of its pink to purple flowers and its tuberous roots, used in Native medicine (see p. 1120). [Cf. *The Bower Manuscript* (Hoernle, transl.), 1893-7, 96; *Pharmacog. Ind.*, ii., 534-6; Dutt, *l.c.* 323.]

I. hederacea, Jacq.; *Rec. Bot. Surv. Ind.*, iii., 244. The *nīl-kalmi*, *baunra*, *bīldi*, *kodī*, *kālā-dānā*, *kākkatān-virai*, etc. An annual hairy twiner, cultivated in India, but also found wild. The seeds known as *kālā-dānā* and *mirchai* are purgative and resemble jalap in their action. They were made official in the Pharmacopœia India in 1868. The market rate is about 4 annas per lb. Hooper (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1905-6, 32-3) says that the seeds contain 8.05 per cent. of resin resembling *convolvuline*, but in addition are rich in albuminous substances and contain 14.02 per cent. of a nauseous fat—a disadvantage in internal administration. [Cf. *Pharmacog. Ind.*, ii., 530-4; Henry, *Econ. Bot. China*, 1893, 49; Firminger, *Man Gard. Ind.* (ed. Cameron), 1904, 476.]

Jalap.

I. P r, Hayne. Jalap. A climber, native of the Mexican Andes, at altitudes from 5,000 to 8,000 feet above the sea. In its native habitat rain falls almost daily, and it flourishes best in shady woods with a deep rich humus soil.

In India it is cultivated on Dodabetta in the Nilgiri hills, and in the North-Western Himalaya at Mussourie. The crop is an exhausting one. Formerly the plant was grown among the cinchona trees, but this system has been abandoned, since while the jalap flourished the cinchona was injured. Plants may be obtained from cuttings set under shade in a moist, sandy soil, but for cultivation on a large scale the smaller tuberous roots may preferably be used. These are placed

one foot apart and at a depth of about six inches within trenches filled with farm-yard manure. As the plants grow, stakes require to be fixed for them to climb on. A return may be expected in the third year, and every third year thereafter. In Ootacamund it has been found that an acre of jalap yields 5,000 lb. of green tubers, or say 1,000 lb. of powder. The drying process is a difficult one, as there is frequently considerable loss through mouldiness and fermentation. It is said this may be prevented by cutting the tubercles in slices.

Medicinally, jalap is well known as a hydragogue purgative, its action being due to certain resinous principles. The selling price has been given at about 2s. 3d. per oz. [Cf. Nicholls, *Textbook Trop. Agri.*, 1892, 237-40; Hooper, *Effect of Phosphatic Man. on Growth of Jalap* (Reprint from *Pharm. Journ.*), 1896; *Kew Bull.*, 1897, 302; *Brit. Pharmacop.*, 1898, 165; Thorpe, *Dict. Appl. Chem.*, 1900, iii., 349; *Pharm. Soc. Mus. Rept.*, 1895-1902, 62-3; *Pharm. Journ.*, 1904, lxxii., 284-5.]

abitat.—Presumably a native of America, but is extensively cultivated in India. Two forms are met with, one with red, the other with white tubers. Evidence points to its having apparently reached the Pacific Islands in prehistoric times, and to a cultivation in China in the second or third century of our era. Asa Gray (*Scient. Papers*, 1889, i., 317-20), reviewing the account given in De Candolle's *Origin of Cultivated Plants*, gives full particulars of the literary evidence in favour of an American origin. The first mention of the plant appears to be by Peter Martyr, who in the 9th book of his *2nd Decade* (written about 1514), gives *Batata* among the fruits of the province of Uraba, Darien, and in his *3rd Decade* names them among the plants growing in Honduras when Columbus landed in 1502. Other early Spanish travellers, e.g. Cieca de Leon, Jean de Lery, etc., also refer to the finding of sweet potatoes in Peru and Brazil. Clusius, moreover (*Rar. Stirp. Hist.*, 1576, ii., 297-9), states pointedly that they grow wild in the New World and adjoining islands, whence brought to Spain. Nothing very definite can be learned of its introduction into India. The plant is figured and described by Rheede (*Hort. Mal.*, 1688, vii., 95, t. 50) and by Rumphius (*Herb. Amb.*, 1750, v., 370, t. 130). Carey (*As. Res.*, 1808, x., 18) discusses the method of cultivation pursued in Dinajpur, and Roxburgh (*Fl. Ind.*, i., 483) speaks of the red sort as cultivated all over the warmer parts of Asia.

Cultivation.—The area under the sweet potato in India cannot be definitely ascertained. It is grown all over the country from the Panjáb, the United Provinces, Rajputana, Central India, the Central Provinces, Bengal, Assam, Bombay, Madras and Burma. In Bengal it is more important in the eastern tracts, such as Bogra and Bhagalpur, than in the western and central divisions. Taking India as a whole, it is planted from August to November and reaped from December to May, the variations being a consequence of local climatic conditions and methods of propagation. A full account of its production in Bombay is given by Mollison (*Textbook Ind. Agri.*, 1901, iii., 193-7), of which the following summary may be accepted as true of India generally. The best soil is a light friable one, well prepared by deep tillage. The crop does not thrive unless the land be naturally dry. It is generally grown during the cold season and under irrigation, but on light, dry land a rain crop may be produced. The land is prepared during the monsoon by frequent ploughings, and in September farmyard manure at the rate of thirty cart-loads per acre is given. Before planting, irrigation beds are formed of various sizes according to local circumstances.

Planting usually takes place in October-November. The crop is propagated by cuttings from fairly mature portions of the stem, each with three nodes or leaf-buds. Two nodes are placed underground, 2

weet
Potato.Cultiva-
tion.

Seasons.

Propagation.

to 3 inches deep, while the other node is left free. The cuttings are usually placed along ridges, though sometimes in flat beds. The ridges are about 18 inches apart and the cuttings are deposited one foot apart on each side of the ridge, half-way between the crest and the bottom of the furrow. Cross furrows are also drawn which form channels for irrigation. Weeding should be attended to and the crop watered every eight or twelve days. Care must also be taken to prevent the plants rooting at the nodes, for otherwise small tubers of no value will be formed at the points of attachment and these will deduct from the growth of the large tubers at the main root.

Yield.

Yield.—If planted in October–November the crop should be ripe in April and the tubers lifted at once, else much damage will be done by rats and white ants. The vines or *haubus* are reaped before the tubers are dug. A good crop may yield six tons per acre, worth about Rs. 300. The cost of cultivation in the Surat district Mollison gives as Rs. 134.

Alcohol.

Sugar and Alcohol.—The sweet potato contains more dry starchy and sugary matter than the ordinary potato, but less nitrogenous substance. Analysis shows it to possess about 10 to 20 per cent. of sugar and about 16·05 per cent. of starch. It is said to be an excellent source of alcohol, 100 kilos of tubers yielding about 12 to 13 litres of absolute alcohol.

Recently it has been largely cultivated in some parts of the world as a source of sugar. By the Natives of India it is commonly used as food, either cooked in curry or boiled, roasted or fried.

Ores.

PRODUCTION.—Iron is commonly said to exist in nature in two great classes of workable ORE—(1) Carbonates and clay ironstone, and (2) Oxides, like hematite and magnetite. The CARBONATES consist essentially of two kinds: (a) those in which the salt is crystalline and little admixed with earthy matter, and (b) those in which a larger or smaller amount of clay is intimately intermixed with the ferrous carbonate. The former is *spathic* iron ore and the latter *argillaceous* ore or clay ironstone. Clay ironstone exists in large deposits in many coal measures and is then known as black-band. The OXIDES may be spoken of as of three kinds (a) anhydrous ferric oxide; (b) hydrated ferric oxide; and (c) a mixture of ferrous and ferric oxides such as the magnetic oxide of iron. Hughes Buller has recently sent from Baluchistan a natural mineral known as *khaghāl* or *lagh*, which is employed as a dye. This has been ascertained to be an impure sulphate of iron. “The most abundant iron ores are the minerals magnetite and hematite which occur in numerous places with quartz, making quartz iron-ore schists which are generally members

of the Dharwar and other Archæan schist series. The most conspicuous examples of this class occur in the Salem district and the Sandur State in the Bellary district of the Madras Presidency, and in the Chanda, Raipur, and Jubbulpore Districts of the Central Provinces. The chief ore now used at the Barakar iron-works for the manufacture of pig-iron is clay ironstone, containing 45 to 48 per cent. of iron, and occurring as nodules in shaly formation separating the Barakar and Rániganj stages of the Dámuda series in Bengal" (*Imp. Gaz.*, 1907, iii., 145-6).

Most Abundant.

Notwithstanding the fact that rich deposits of one or other of these various iron ores exist here and there all over India, and have, from the most ancient times, been worked up in a desultory manner by the Natives, still there has been but one successful attempt on European lines and by modern appliances. Indeed some of the recent investigations conducted in India would seem to establish belief that few of the important supplies of ore are of sufficiently high merit to defray the cost of carriage to Europe (or even to Indian centres of fuel supply) and leave a margin of profit. The opinion would thus appear to have been borne home that the expansion of India's iron production must, for the present, be looked for in the immediate vicinity of fuel supplies.

Successful Attempt.

Proximity to Fuel.

South India.—Some few years ago many persons urged that if it paid to convey Spanish ore to England to be there made into "pig" which in the ordinary course of trade was profitably carried even to India, it must of necessity pay to convey the rich ores of Madras to the coal mines of India to be there worked up in competition with the imported foreign metal (*Watt, Mem. Res. Ind.*, 1894). It was also even upheld that the time might soon arrive when England would have to look to Salem for its supplies of magnetic ore. In his presidential address to the Iron and Steel Institute (of May 1893), for example, Mr. W. Richards suggested that Indian ores could and should be substituted for Spanish. And still further it was loudly proclaimed that with some co-operative organisation of the Forest Department, South India might easily supply charcoal in such abundance and at such a price as to admit of production of iron after the fashion pursued in Styria and certain districts of America. These and other such opinions led to various technical investigations and reports on the part of experts employed both by private individuals and by Government. The Secretary of State for India, for example, submitted the then available information to Mr. Jeremiah Head, formerly President of the Institution of Mechanical Engineers, for favour of his views, the result being a most valuable contribution dated May 2, 1896. This is concluded as follows:—"I regret to have to say that in my opinion it is not at present practicable to conduct an iron industry at or near Salem upon the methods pursued in Styria and certain districts of America where charcoal is employed." It was perhaps but natural that with a subject which had not passed from the stage of personal opinion to that of ascertained results, some at least of Head's statements would be challenged. His final conclusion, in fact, has by no means been universally accepted in India, and the accuracy of the information on which he based his calculations of cost of production of iron, as also the supply of crude ore for direct export to Europe, has been called into question. The Board of Revenue, Madras, for example, observed that "If it can be shown that Mr. Head's estimate can be safely reduced to Rs. 50 per ton f.o.b., as the Board believes that it can be, and freight can be obtained at 15s. per ton, the estimate taken by

outh India.

Magnetic Ore.

Charcoal.

Jeremiah Head's Report.

Data called into Question Board of Revenue.

Mr. Head (at page 18 of his report), it will be possible to deliver Kanjamalai pig-iron in England for £3 15s. 10d. per ton, being 5s. 2d. below the minimum value of imported Swedish pig, £1 4s. 11d. below the maximum, and 12s. 3d. below the average. The same iron could also compete still more favourably with Swedish pig imported into Madras, Calcutta and Ceylon."

Test
Consignment.

In 1898 a consignment of Kanjamalai Salem ore was sent to England to be tested along with Indian coke supplied for that purpose. The experiment was conducted by Messrs. Bolckow, Vaughan & Co. at Middlesborough, with the result that it was found to contain only 40 per cent. magnetic iron—in fact, that it was not worth exporting. This led to an acrimonious correspondence in the public press, in which it was affirmed that the sample sent was not selected ore but an average of the whole rock, and thus contained much that ordinarily would never be conveyed from the mine to the smelting furnace. It was urged that the results of previous investigations (such as those conducted by Dunstan, *Imp. Inst. Tech. Repts.*, 12-22) showed a much higher average merit. Six samples examined gave 56.95 average, with the highest 70.06 and the lowest 36.44 per cent. of iron.

Major Mahon's
Opinion.

The Porto Novo Iron Company, founded by Mr. Josiah Marshal Heath, was the earliest and perhaps the most persistently worked concern in India. It was founded in 1830, changed hands more than once, and was finally dissolved and its privileges surrendered to Government in 1874. For thirty years a large quantity of iron was manufactured, and failure, as Major R. H. Mahon says, was not due to lack of iron ore or its quality, but to inexperience, defective machinery, and want of capital. He is, moreover, strongly of opinion that all existing difficulties will be overcome and iron production from the South Indian supplies made an industry of the greatest possible value. Persons interested in this subject should therefore procure Mahon's admirable report. It would thus seem that the whole subject needs to be even still further investigated before it can be regarded as satisfactorily disposed of one way or the other.

C. Prov.

Central Provinces and Orissa.—Hardly less satisfactory are the results of the inquiry made regarding the iron supplies of the Central Provinces. The report of investigations conducted by Mr. E. P. Martin and Prof. Henry Louis (on behalf of the Right Hon. Sir E. Cassel) will be found in *The Agricultural Ledger*. Speaking of the Jabbalpur district, more especially the Agaria ridge, these distinguished investigators say "the entire district undoubtedly contains considerable quantities of ferruginous material, but the latter is nowhere concentrated into what may be called a workable ore deposit showing the essential characters of steadiness and persistence which are indispensable in a deposit that is to form the basis of an important industry." The conclusion arrived at may be said to be that considerable though the iron resources of the district are, they are not such as would warrant the erection of iron and steel works with any prospect of commercial success. In the Mayurbhanj State, in Raipur and in the Chanda districts, Messrs. Tata, Sons & Co. of Bombay organised prospecting operations on a large scale and employed Mr. C. P. Perin and Mr. C. M. Weld as their experts. As a result it has been decided to erect iron and steel works near Kalimati on the Bengal-Nagpur Railway with the intention of using the Mayurbhanj ore in conjunction with fuel from the Jherria Coal Field. It may thus fairly well be assumed that this new departure marks an era in the metal industries of India.

Agaria Supply.

Chanda Supply.

A Company known as the Tata Iron and Steel Company, Ltd., was

floated at Bombay in July 1907 with a capital of 2½ lakhs of rupees. Since then Government have sanctioned the construction of a broad-gauge railway from Kalimati (the site selected for the works) to the ore-fields of Mayurbhanj State, a distance of about 45 miles. Coal lands have been purchased by the company in the Jherria field; limestone quarries secured near Katni; manganese ore is being opened up in Salaghat; designs for the works have been accepted and progress made in clearing the site for the erection of the blast furnaces which are expected to commence operations about the end of 1910.

Bengal.—It has, however, to be admitted that so far as actual results are concerned, the ore utilised in India is very nearly confined to that worked up by the Bengal Iron and Steel Company in its works at Barakar. In the *Review of Mineral Production*, Holland gives the ore raised in Bengal during 1898 to 1903, which shows for the six years an annual average output of 57,678 tons valued at £8,338, and a value per ton of 2·89s. Up to the present time, he observes, the Barakar Iron and Steel Company has manufactured pig-iron only, of which two blast furnaces have turned out 35,000 tons of pig-iron a year. Since then a third blast furnace has been added and an unsuccessful attempt made to manufacture basic steel. The history of past adversity and present prosperity of the Barakar works is the story of the failure of unskilled impersonal enterprise contrasted with skilled individual energy when combined with capital and commercial acumen. Their subsequent production was 65,115 tons in 1904; 97,698 tons in 1905; and 69,397 tons in 1906.

FOUNDRIES AND INDUSTRIES.—Iron and Brass Foundries are not separately returned, so that they have to be dealt with conjointly. They are scattered all over the country, but with the exception of the Barakar Iron and Steel Company, the railway and engineering workshops and foundries of Calcutta, Bombay, and certain other large towns, few are of any importance. In 1903 there were 78 foundries in all India giving employment to 22,568 persons, and in 1904, 89 employing 24,256 persons. Three years previously the corresponding figures were 70 and 17,980, so that there has been a considerable expansion; but these returns take, of course, no cognisance of the village blacksmith nor the workers in brass and copper. In the *Records of the Geological Survey of India* (1906, xxxiii., pt. i., 12-3) it is stated that the value of Bengal ore works out to an average of Rs. 2-4a. (3s.) per ton. For the rest of India, the ore being of a higher quality and raised at places often distant from the railways as well as the ports, a higher average prevails, say Rs. 4. The returns for 1904 show 71,608 tons of ore used, valued at £12,617. In the Central Provinces there were 441 small direct-process furnaces at work. [*Cf. Moral and Mat. Prog. Ind.*, 1905-6, 115.]

Local Manufactures.—The exports and re-exports are not of sufficient importance to necessitate separate treatment. A feature of great potentiality that bids fair to foster local manufacturing enterprise, is the decision of the Indian Railway Board to place Indian engineering firms in a position to tender publicly for a portion of the annual requirement of stock. The tenders are to be confined for the present to the supply of frames and bodies only, the requisite wheels, axles, springs and draw-bars to complete wagons being indented for from England as heretofore. Subject to the material being satisfactory, iron and steel of Indian manufacture should be used whenever possible.

Indigenous Industries.—There would seem to be “no doubt that the existing manufacture of wrought iron by a direct process was widespread in the country before the date of the most ancient historic records, while the manufacture of the ancient *wootz* anticipated by many centuries the cementation process, developed in Europe, for the manufacture of the finest qualities of steel.” “The Native iron-smelting industry has been practically stamped out by cheap imported iron and steel within range of the railways, but it still persists in the more remote parts of the Peninsula and in some parts of the Central Provinces has shown signs of slight improvement” (*Imp. Gaz.*, 1907, iii., 145). According to Mr. Syed Ali Belgrami, the Nizam’s Dominions furnished the material from which the famous Damascus blades of the Middle Ages were made. To this day Hyderabad is noted for its swords and daggers. Holland observes that so far as official returns are concerned, the Central Provinces show the highest production of iron, viz. from 2,400 to 4,800 tons; but there is also a sensible industry surviving in Bijawar, Panna and Orchha amongst the Central Indian States, as well as in Mysore and in some parts of the Madras Presidency. “Steel is made, both in the form of ingots by the carburisation of wrought-iron in crucibles, and, on a much smaller scale, by the decarburisation of cast-iron shot in a small open hearth.”

The antiquity of the Indian knowledge in iron may be judged of from the famous pillar at the Kutab near Delhi; from the numerous examples that exist of wrought iron; from the hammered and perforated door panels both in iron and brass to be seen at the ancient palaces and tombs; and from the superb collections of arms preserved by the princes and nobles. Burma has for many years been known to have attained high proficiency in wrought iron. Near the Arakan pagoda of Mandalay numerous workshops exist for the production of the iron *thees* or the umbrellas placed as weather-cocks on the pagodas of Burma. At the pagodas, balustrades in iron are also frequently used, and this demand has given birth to a fairly large import trade in very inferior cast-iron imitations of fine old Burmese designs in wrought iron. Of Western India, Baroda is noted for its wrought-iron balustrades. The engraving and carving of iron and steel was some years ago an important industry in India, and Kanara, Madura, Malabar, Vizagapatam and Mysore were famous for their works of this class. The art is still practised at Udaipur, Jaipur, and Jodhpur. Hyderabad, Deccan, and Kach are famed for their arms; and the gold and silver damascened soft-steel wares such as armour, swords, shields, caskets, etc. (*koftgari* work) of Sialkot, Serhoi, Jaipur, are traded in all over India and largely exported. The decline of the Sikh power and the modern change in the methods and materials of warfare struck, however, a deadly blow at the damascening art, and a serious decline both in the amount and quality of the work has for years past been manifest (*Ind. Art at Delhi*, 1903, 14-45, 460-2).

T. ADE.—I ports.—It is difficult to give anything like an accurate conception of the total traffic in iron. The local production is but imperfectly known; an error must therefore always exist. A large number of articles that are partly constructed of iron are sure to be returned under other headings, but the figures under hardware and cutlery, iron, steel, machinery, railway plant, rolling stock, locomotives, etc. (Merchandise and Government Stores), give some idea of the vast magni-

tude of the traffic. The IMPORTS shown under these headings were collectively in 1899-1900 valued at Rs. 13,34,14,503; in 1901-2 at Rs. 15,11,06,431; in 1903-4, Rs. 19,58,09,778; in 1904-5, Rs. 20,30,66,366; in 1905-6, Rs. 23,01,10,532; and in 1906-7, Rs. 26,86,49,605 (£17,909,973). Thus the traffic is by no means unimportant, but it may be useful to direct attention to certain items of it that more especially may be called Iron. The imports of CAST-PIG were in 1899-1900, 263,563 cwt., valued at Rs. 7,95,040; in 1901-2, 291,422 cwt., valued at Rs. 8,73,347; in 1903-4, 531,953 cwt., valued at Rs. 13,84,888; in 1905-6, 636,163 cwt., valued at Rs. 16,17,966; and in 1906-7, 667,285 cwt., valued at Rs. 18,43,167. Practically the whole of these imports came from the United Kingdom, the only other country of importance being Aden. Of BAR-IRON, the imports were in 1899-1900, 499,678 cwt., Rs. 30,07,124; in 1901-2, 855,106 cwt., Rs. 49,67,024; in 1903-4, 650,409 cwt., Rs. 35,74,266; in 1905-6, 781,360 cwt., Rs. 39,89,004; and in 1906-7, 606,604 cwt., Rs. 35,18,998. Under the heading of STEEL-BARS the imports were in 1899-1900, 500,676 cwt., valued at Rs. 33,21,024; in 1901-2, 974,038 cwt., Rs. 54,93,840; in 1903-4, 1,115,933 cwt., Rs. 59,49,191; in 1905-6, 1,963,574 cwt., Rs. 95,42,895; and in 1906-7, 1,402,762 cwt., Rs. 74,92,013. In the iron and steel bar traffic Belgium has practically usurped the United Kingdom and for some years past poured into the country large quantities of cheap stuff that has found a ready and expanding market. Of PIPES and TUBES in 1899-1900 the imports were 257,118 cwt., Rs. 25,32,277; in 1901-2, 322,520 cwt., Rs. 29,40,404; 1903-4, 821,783 cwt., Rs. 57,81,098; 1905-6, 514,060 cwt., Rs. 38,19,850; and in 1906-7, 668,539 cwt., Rs. 51,17,286. In this traffic the British manufacturer more than holds his own, the only important competitor being the United States. Of SHEETS and PLATES (all kinds) the imports in 1899-1900 were 1,104,289 cwt., valued at Rs. 1,04,42,871; in 1901-2, 1,298,985 cwt., Rs. 1,22,15,307; in 1903-4, 1,636,592 cwt., Rs. 1,45,60,655; in 1905-6, 1,783,999 cwt., Rs. 1,59,41,040; and in 1906-7, 2,190,764 cwt., Rs. 2,20,45,396. The supplies come mainly from the United Kingdom, the only other country of importance being Belgium, the trade from which would appear to be declining.

These illustrations may be accepted as fairly representative of all the special headings of the iron trade proper. Space cannot be afforded to indicate the traffic in the manufactures that are only partially made of iron, such as machinery, railway plant, etc. It may have been observed that a steady rise is taking place in the imports. Even the figures exemplified are sufficient to show that there is room for a large iron manufacturing industry; and when this is established, the production of rails, rolling stock and machinery would soon follow in the wake of the furnace and the foundry.

The grass, from the most ancient times, has, in the localities where it abounds, been extensively used for making ropes, string and mats (see p. 776), and utilised in the construction of rope bridges, and to some extent takes the place of jute in agricultural sacking.

Mats.

Identification.

Bhabar is often associated with the sedge *Eriophorum comosum* (D.E.P., iii., 266), and the two doubtless are sometimes used mixed together, but for many years it was incorrectly supposed that *bhabar* was *Eriophorum*. Sir D. Brandis was the first to recognise that Royle, Wallich and others were in error in overlooking the grass *Ischaemum* as the most important, if not the true *bhabar*. Stewart (*Journ. Agri.-Hort. Soc. Ind.*, 1863, xiii., 293), while acknowledging his indebtedness for this correction, expressed the opinion that the grass should, in the future, play an important part as a paper material—he was thus apparently the first to suggest that use for the grass. Duthie led to a true identification botanically, and Sir George King pioneered the trade as a paper material (see pp. 865-8). In the Annual Report for the Botanic Gardens of Calcutta for 1893-4, he tells us that he had sent home, in 1873, samples of the grass to a paper-maker in Scotland, who reported favourably on it, and again in 1877 had furnished the late Mr. Routledge, through the India Office, with a consignment for experiment in Sunderland. Investigations were also made in India from 1882, the first by Mr. Deveria, and finally by the Bally Mills Company, Ltd., and others, until the grass became firmly established as a paper material.

Paper Material.

Supply.

The *Kew Bulletin* and the *Indian Forester* have devoted much attention to this subject for some years past, and the Annual Administration Reports of the Forest Department have recorded the measures taken to foster and extend production. [Cf. Gamble, *Ind. For.*, 1893, app., xix.; Fischer, *Ind. For.*, Nov. 1903, xxix., 516.] The grass has thus been systematically placed before the public. It has, in consequence, become an assured paper material, restricted alone by the insufficiency of the supply. The attempt has accordingly been made to cultivate the plant in localities more accessible to the paper-mills, thereby lowering the ruinously heavy freight charges. More or less successful experiments of this kind have been conducted in Poona, Mysore, Hyderabad Deccan and in Hyderabad Sind. Systematic cultivation has also been undertaken in Manbhum, Birbhum and Murshidabad. In Poona it has been announced that the yield is 24 cwt. of dry grass per acre. It was, however, ascertained that when grown on soils of a better class than its wild habitat or under warmer and moister conditions, it tends to flower too profusely, and this lowers its value as a paper material. A consignment sent in 1898 from Poona to London, by Woodrow, was accompanied with the statement that it could be delivered on board ship at Bombay at Rs. 40 per ton.

Cultivation.

Yield.

Cost.

Bengal.

As marking the progress made, the following jottings, taken from official and other publications, may be here given. In the Bengal Forest Department Report for 1895-6, we read that the grass had been fairly extensively planted in Sahibganj, and that the produce sold readily at 12 to 14 annas a maund, and fetched at the mills Rs. 1-4 to Rs. 1-7, the railway freight being not over

ISINGLASS AND GELATINE

3 annas 5 pies a maund. Mr. Wild, while Conservator of Forests in Bengal, devoted much attention to the supply of paper materials to the Calcutta mills, and among other subjects took up the study of *bhabar*. He then wrote, "When it is understood that the Calcutta mills turn out 360 tons of paper a week, or an equivalent of, say, 500,000 maunds a year, there is room for wood pulp as well as grass. It is believed that a consignment of 200 tons of pulp left Calcutta for Glasgow in 1896, at £4 2s. per ton. If the cost could be reduced to £3 10s. per ton—and there seems no reason why it should not—it would, it is thought, compete with esparto. Surprise has been expressed that the planting community in India does not pay attention to the cultivation of grasses, etc., for paper-making. There is evidently profit in it, and what is more, with the output of paper mills increasing every year, the demand, for some time to come, will be expansive."

In Murshidabad, according to Mr. B. C. Bose, Assistant Director of Agriculture, Bengal, it is now planted in clumps along the borders of mulberry fields. "Two cuttings are taken in the year, one in September and the other in March. With irrigation three or four crops can be had. This is at any rate the experience in Poona. The March crop is cut after the grass has flowered, and yields very inferior fibre. No steps are taken to remove the flower stalks, no doubt owing to the cost of picking them out. The September crop does not flower, and yields the best fibre. The people look upon the formation of the flower stalks as a necessary evil, which they have no means of checking." The Calcutta mills draw their supplies from Sahibganj, Chota Nagpur and Nepal (the Terai), the last mentioned having, in recent years, contributed fairly largely. The Report issued by the United Provinces and Oudh for 1898-9 affirmed the annual production to be 200,000 maunds. The cutting in these provinces is said to commence at the end of October. That supply is very largely made use of in cordage.

I GLA , LATIN , GLU AN G L .—There are commonly said to be five classes of Cements :—(a) Calcareous (pp. 713-4) ; (b) Gelatinous (animal, p. 543) ; (c) Glutinous (vegetable, p. 293) ; (d) Resinous (see *Tachardia lacca*, p. 1063) ; and (e) Mixed Materials, non-resinous. With the first mentioned lime is essential, and they are collectively designated Mortars. Gelatine is prepared from animal flesh, bones, skins, hoofs and horns. It is a purer article than glue, which is made, as a rule, from the parings of hides and the refuse of the tan-yard generally. A mixture of glue and shellac is often used in India, the lac preventing the penetration of moisture, which softens and renders ordinary glue often useless. There is no chemical difference between gelatine, glue and isinglass. The purer transparent forms are used for culinary purposes. Fish-glue made from fish-bones is largely employed in India, and may be had all over the country, but no information exists as to the centres of production or the methods of manufacture. Edible Swallows' Nests may be described as Indian gelatine (see *irds*, p. 138). Gelose is prepared from several *ALGÆ*, designated in India as *agar-agar*, and in European commerce as China Moss. The best-known example is *Gracilaria lichenoides* (*D.E.P.*, iv., 174-5). Numerous glutinous cements and pastes are in use in India, the commonest of all being made with the water obtained on boiling rice. [*Cf. GLUE* :—Hoey, *Monog. Trade and Manuf. N. Indian
Elephant.

ELEPHANT.—No account of Ivory would be complete without some mention of the ELEPHANT. In the *Dictionary* will be found a fairly detailed account of the Indian species. From the most ancient classic times this sagacious and most useful animal has been known, and the methods of capturing and taming it can hardly have been changed materially for the past two thousand years. The Hindu god *Ganesha* (son of *Siva*) is represented with an elephant's head on the body of a man. In the *Rig Veda* the elephant is the animal with a hand, and in the *Atharvan* he is the mightiest of animals. In the wars of the *Ramayana* and the *Mahabharata*, elephant corps were employed and Indra's Vahan is the elephant *Airavat*. According to Monier Williams (*Buddhism*, 23-4, 84, 525), the elephant is with the Buddhists the most sacred of animals. Among European writers, Megasthenes (300 B.C.), Strabo (25 B.C.), Arrian (*Indika*, 150 A.D.; ed. McCrindle, 213) and Aelian (250 A.D.) give full particulars regarding the manner of hunting and capturing the elephant, the degree of its domestication and its use in warfare. Strabo (xv., 1, 41-3, 704-7) gives a chapter on the *kheddahs* that might be read as an abridgment of Sanderson's corresponding chapter in *Thirteen Years Among the Wild Beasts of India*. The African elephant appears to have similarly been tamed, and the Carthaginians employed them as fighting animals. The inscription at Adule (recorded by Cosmas, 545 A.D.) alludes to this special use. [Cf. Vincent, *Periplus*, app., 56.] During the ascendancy of the Roman Empire, elephants became quite common in Europe; but they ultimately disappeared, and for several centuries seem to have been altogether forgotten, and what is most significant, the African elephant, since the fall of Carthage, has hardly since been in such a complete state of domestication.

Elephant.

European
Travellers.

The White
Elephant.

Passing over a gap of several centuries, little is said even of the Indian elephant, till Abd-er-Razzak (*Narr. of Journ. in Ind.*, 1442, in *India in 15th Century*, (Major, transl.), 27, 36) described the elephants owned by the King of Vijayanagar near Bellary, and the method of capturing and taming them then prevalent. Nicolo Conti, speaking of Ava (*Travels in the East*, in *India in 15th Century*, 11-2, 37), alludes to the white elephant owned by the king. Athanasius Nikitin (*Travels in India in 15th Century*, 12) discusses the elephants seen by him. Varthema (*Travels*, 1510 (ed. Hakl. Soc.), 125-31) gives a most graphic account of the city of Vijayanagar and vivifies the ruined elephant stables, which in their desolation are to-day objects of special inspection by the curious. Garcia de Orta published at Goa the first edition of the *Colloquies* (1563, xxi.), and in that work we are given the Arabic name *fil*, the Deccan name *ati*, the Kanarese *aceti*, the Malabar *aue*, and the Ethiopian *ytembo*. Mention is made of the large amount of African ivory annually imported into Cambay, and of the existence of wild elephants in Orissa, Bengal, Patna, Pegu, Martaban, Ceylon and Siam. This is followed by Acosta (*Tract. de las Drogas*, 1578, 417-48), who gives for the time when produced two admirable plates showing the wild and tame elephant with its war *howdah*. In the *Voyage of Linschoten*, some additional useful facts are told of Indian elephants. Baber (*Memoirs*, 1525 (Leyden and Erskine, transl.), 315-6) enumerates and briefly describes the animals and plants seen by him in India which he regarded as peculiar to that country, and assigns the first place to the elephant, which he speaks of as abundant in parts of the country where, during the memory of living man, no wild elephants have been known. Abul Fazl (*Ain-i-Akbari*, 1590 (Blochmann, transl.), 117, etc.) details the particulars of the Emperor's elephant stables, and of the rearing of that animal under domestication. Barbosa (*Coasts East Africa and Malabar* (ed. Hakl. Soc.), 167-8) furnishes an account of how elephants were caught in Ceylon and exported to India. Subsequent to the dates mentioned, many European authors have contributed to the stock of present-day knowledge regarding this most useful animal. [Cf. Pyrrard, *Voy. E. Ind.*, etc., 1601 (ed. Hakl. Soc.), ii., 343-6; Clusius, *Hist. Exot. Pl.*, 1605, 166, 260; Terry, *Voy. E. Ind.*, 1622 (ed. 1777), 134 (gives a long and most interesting account of the domestication and uses of the elephant in India); Mandelslo, *Travels*, 1662, in Olearius, *Hist. Muscovy*, etc., 51; Tavernier, *Travels Ind.*, 1676, ii., 161, 317; Thevenot, *Travels in Levant, Indostan*, etc., 1687, pt. iii., 45; Ovington, *Voy. Suratt*, 1689, 191-4; Fryer, *New Acc. E. Ind. and Pers.*, 1672-81, 35, 96, 211; Milburn, *Or. Comm.*, 1813, i., 63; etc., etc. For recent works consult citation given in the *D.E.P.*, iii., 208-9; also *Journ. Bomb. Nat. Hist. Soc.*, 1895-7, x., 133-5; *The Elephant in Burma*, 1897-8, xi., 322-6, 335; 1903, xiv., 151-5; Jardine, *Elephant Shooting*, xiv., 160-2; Blanford, *Fa. Br. Ind. (Mammalia)*, 463-7.]

Rearing under
Domestication.

CAPTURE OF ELEPHANTS

Distribution.—The elephant frequents the forest-clad portions of India and Ceylon from about Dehra Dun in the north along the foot of the Himalaya to Assam, Chittagong, Burma, Siam and Cochin-China, also in the forests of the Deccan, the Western Ghats, Mysore and South India. As a rule the elephant does not ascend much above 5,000 feet, but in Manipur and the Naga hills (Japvo) it has been met with at close on 8,000 feet. The chief centres of capture are in Assam (Garo hills more especially), in Mysore and Ceylon. It is generally affirmed that while all the Indian elephants constitute but one species—apart from that of Africa—there are several very distinct races such as those of Nepal, Assam, Burma and Mysore. The Nepal animal is small and especially adapted for life in a hilly country; the Shan elephant is tall, massive and handsome, but like the Ceylon race is often tuskless. Those of Burma and Chittagong are small and well suited for hilly countries, while the Assam animal is large and massive, hence better adapted for hunting purposes. The Natives classify the recognised races into *kumeriah*, the royal or princely, the thoroughbred; *mîrga*, a tightly built and long-legged, arched-backed animal, suggestive of the deer *mîrga*; and *dwasâla*, the intermediate of the two former and the ordinary domestic or working elephant, the *mîrga* being used in quick marching.

Chief Localities.

Races.

In India the animal is caught purely and simply for domestic purposes and is never (as in Africa) ruthlessly destroyed on account of its ivory. It is now captured exclusively by the *kheddah* system, and never by the cruel methods in pits, etc., formerly pursued. But there seem indications that, far from being exterminated, the Indian elephant is increasing in a higher ratio than the captures, and that the time may come when it may be necessary to keep the multiplication under control, so as to protect the cultivation of the tracts adjacent to the forests.

Kheddahs.

The chief Indian mart where elephants are offered for sale appears to be Sonopoor, near Patna, the *mela* there held being some time in October or November. An elephant costs about £40 to capture, and may be sold for £150. A full-grown elephant will weigh from 3 to 3½ tons, and stand from 7½ to 9½ feet at the shoulders. It is an adult at twenty-five years (but a calf may be obtained at thirteen to sixteen years), and its full age is 120 years. The only pace of the elephant is the walk, capable of being increased to a fast shuffle of about fifteen miles an hour, but for short distances only; it can neither trot, canter nor gallop. It cannot jump, can never have all four feet off the ground at one time, and hence a trench 7 feet wide is to it impassable, though the step of a full-grown animal is 6½ feet. The elephant will eat 600 to 700 lb. of green fodder, but is usually under-fed, getting 250 to 400 lb., and is fed mainly on leaves and boughs of trees. Most of its ailments proceed from unsuitable or insufficient food.

Price.

Pace.

Food.

IVORY (ELEPHANT'S TOOTH).—Mention has been made of the fact that the Ceylon elephant has frequently no tusks. In India a tuskless male is called a *mûkna*. The tusks of the Asiatic animal are considerably less valuable than the African. As a rule, the nearer the equator, the larger, finer and more expensive the ivory; but there are in addition many local manifestations. African ivory is closer in grain and not so liable to turn yellow nor to warp and split as the Indian; moreover, the ivory of the east coast of Africa is superior to that of the west. By "dead ivory" is meant ivory that has been found on the ground or

Ivory.

Equator.

African versus Indian.

stored for a considerable time, until it has lost the oil or gelatine that gives elasticity to "green ivory." All the finer and more expensive ivory carvings are, as a rule, done on the best African ivory; and even in inlaying, the hair lines are invariably in the bluish-white African article, the larger patches being in the dull chalky Indian quality. For the microscopic structure of ivory, consult Hanausek (*Micro. Tech. Prod.* (Winton and Barber, transl.), 1907, 422-8).

Oldest Sample.

Perhaps one of the oldest samples of Indian ivory on record is that mentioned by Stein (*Ancient Khotan*, 1907, 209, 222, pl. xlviii). This was found in the Khotan oasis and dates from about the 8th century. As a curiosity, it may be mentioned that in the armouries of the Indian princes a large number of daggers will be found, the hafts of which are made of fossil or of walrus ivories. Some of these weapons have often histories that carry them back for one or more centuries; hence the traffic in conveying these special forms of ivory from Siberia or even from Greenland to India, mostly by tedious land routes, must have existed long anterior to the present methods and channels of commerce. For the microscopic appearances of the various fossil and other ivories, confer with Hanausek (*l.c.* 426-9).

Fossil Ivory.

Ivory Carving.

Centres of Ivory Carving, etc.—There are four localities in India and one in Burma that may be spoken of as specially noted for their artistic ivories. These are Delhi in the Panjáb, Murshidabad in Bengal, Mysore and Travancore in Madras, and Moulmein in Burma. Here and there all over the country ivory carving and ivory turnery are met with, but the five localities named produce by far the best work. The chief artistic workers in India are Hindus.

Turnery.

Ivory Turnery, though less artistic, is even more widespread than carving: in fact, most towns have a few workers of this class. Small articles are made by them, such as bracelets (bangles), chessmen, antimony boxes, etc. Some of the better known localities are Agra, Alwar, Bikanir, Jodhpur (more especially Pali), Amritsar, Ludhiana, Patiala, Tippera, Tirupati, Godávári, etc. With the Sikh the use of a comb is almost a religious observance. It is no wonder, therefore, that in Amritsar and other towns of the Panjáb, ivory combs of great beauty are to be had. Here and there fabulous sums are expended on special chairs, *howdahs* and thrones made of ivory, or rather veneered with ivory; so also in the purchase of mats and fans woven by threads cut from the tusk. Ivory mats are often made at Delhi, Bharatpur, Murshidabad, Tippera, etc.

Combs.

Mats.

Inlaying.

Ivory Inlaying.—In many parts of India wood is inlaid with ivory, but there are three localities that are specially noted for the superiority of this class of work. These are Mysore in South India, Hoshiarpur in the Panjáb, and Monghyr in Bengal. Bone is sometimes used as an inferior substitute for ivory in inlaying.

Trade.

Exports.

Trade in Ivory.—The *EXPORTS* of Ivory (raw and manufactured) from India appear to have been declining for some years past. In 1876-7 they were valued at Rs. 55,582; in 1886-7 at Rs. 48,311; in 1896-7 at Rs. 60,501; but for the years 1901-7 have been Rs. 27,740 in 1901-2; Rs. 27,827 in 1902-3; Rs. 26,795 in 1903-4; Rs. 26,956 in 1904-5; Rs. 44,655 in 1905-6; and Rs. 49,583 in 1906-7. The *IMPORTS*, on the other hand, seem to fluctuate very greatly, but on the whole the supply of raw ivory seems to be declining and manufactures increasing. Thus the raw and manufactured ivory imported in 1876-7 were valued at Rs. 24,55,637 (raw accounting for Rs. 24,15,514); in 1886-7

the figures were Rs. 28,81,190 raw and Rs. 1,46,762 manufactured; ten years later (1896-7) the total of both kinds was only Rs. 23,19,229; and in 1903-4 the figures returned were raw ivory Rs. 18,20,766 and manufactured Rs. 2,35,809; in 1905-6, raw Rs. 14,52,379, and manufactured Rs. 2,41,699; and in 1906-7, raw Rs. 12,71,754, and manufactured Rs. 2,24,984.

Thus India is by no means self-supporting in the matter of ivory, but, as shown above, it has for several centuries procured large supplies from Africa. In Indian commerce ivory is spoken of as "elephant's tooth," but a second substance is called "fish tooth." This is of a dirty oily yellow colour, with the texture looking as if crystallised into patches. The significance of being called in every language of India by the same name is suggestive of a foreign origin. It is, as already explained, highly valued for sword and dagger hafts, and is more extensively so used than ordinary ivory. It would appear to be mainly if not entirely the so-called fossil ivory of Siberia—the ivory of the mammoth—a substance that has lain for countless ages in the frostbound drifts of Liakoff and New Siberia. It is also just possible that a fair proportion of the *machlá-ka-dant* of India is hippopotamus or even walrus ivory, the latter, along with fossil ivory, having found its way to India across the land frontier. In fact, from the antiquity of the daggers, etc, with fish-tooth hafts, it seems highly probable that the traffic in the commodity mentioned was a very ancient one—alone destroyed by the growth of fire-arms.

Fish Tooth.

Physic
Nut.

J. C cas, *Linn.*; *Rec. Bot. Surv. Ind.*, iii., 101, 275. The Physic Nut, *bagberenda*, *safed arand*, *rattan jot*, *magalieranda*, *kaat-amunak*, *thinbaw-kyetsu*, etc. An evergreen shrub, indigenous to America, but cultivated in most parts of India.

Garcia de Orta (1563, *Coll.*, xviii.) describes certain seeds which he calls *curcas*, but it is perhaps doubtful if he refers to the seeds of the present species. [*Cf. Ball, Rev. of Garcia de Orta in Proc. Roy. Ir. Acad.*, ser. 3, 1889-91, i., 405.] Heyne regards the milk of this plant as possessing "the exclusive property" of "oxydating silver." When dried in the sun the juice forms a reddish brown, brittle substance like shellac or kino, and is also stated to dye linen black. The seeds yield about 30 per cent. of a pale yellow oil, incorrectly known as Croton Oil, which is used for burning, in medicine as a purgative and emetic, and as an application in cutaneous diseases. It has also been recommended as a substitute for olive oil, in dressing of woollen cloths, and as a good drying oil. Numerous cases of poisoning are on record through eating the entire seed, though used by the Natives as a purgative. Gamble states that in Madras the fruit is sometimes collected and sold, and in Assam the leaves are occasionally used to feed the *eri* silkworm, when other leaves are not available. [*Cf. Heyne, Tracts on Ind.*, 1814, 242, 245; *Pharmacog. Ind.*, 1893, iii., 274; Nicholls, *Textbook Trop. Agri.*, 1892, 205; Henry, *Econ. Bot. China*, 1893, 61; Kirtikar, *Poison. Pl. LAG NARIA

VULGA I

Bottle Gourd

Dye.

Medicine.

J. glandulifera, Roxb.; *lál-bherenda*, *undarbibi*, *addalai*, *dundigapu*, etc. A small shrub common throughout the hotter damp tracts of India, often grown as a hedge. Reputed to produce a green dye. The seeds afford a light yellow fluid oil, which has for long been used as an external application in rheumatism and paralytic affections, but is seldom administered internally, though spoken of as a purgative. [*Cf. Pharmacog. Ind.*, 1892, iii., 272-3.]

D. P.,

iv., 549-52.

Walnut.

JUGLAN

GIA, Linn.; *Fl. Br. Ind.*, v., 595; Gamble, *Man.*

Ind. Timbs., 662-3; Brandis, *Ind. Trees*, 619-20; JUGLANDEÆ. The Walnut Tree, *akhrót*, *ákhör*, *kabshing*, *kól*, *dún*, *ughz*, *thitcha*, etc. A large deciduous tree of the Himalayan forests from Afghanistan to Bhutan at 3,000 to 10,000 feet, and the hills of Upper Burma; also cultivated on the Himalaya, the Khasia hills, and occasionally in gardens on other temperate tracts.

Timber.

The utilisation of the walnut and, accordingly, its cultivation in India date from very remote times. Its chief value lies in its timber. The most important use of the wood is for gunstocks, and as the European supply is becoming exhausted, Gamble points out that it is a matter for serious consideration whether the tree should not be more extensively and systematically cultivated in India.

Burrs.

In Kashmir and throughout the Panjáb it is used for ornamental carving, turnery and fancy work. The average weight is about 44 lb. per cubic foot. The huge warts or "burrs" growing on the stem are also exceedingly valuable, the wood of which is prized by cabinet-makers for veneer work. It is said that a good burr may be valued at about 20s. per cubic foot. These burrs have at times been largely exported from Kashmir to France, and Lawrence (*Valley of Kashmir*, 1895, 352-4) mentions that in one year countless numbers of trees were destroyed by cutting out the burrs, for which a large demand then existed.

Dye.

Medicine.

Food.

The bark is employed as a DYE and MEDICINE and is exported to the plains, where it is used for cleaning the teeth. The fruit, which ripens in July to September, is an important article of food in Kashmir and the North-West Himalaya generally and is largely exported to the plains. The kernel yields a good description of oil, while the rind is employed for tanning and dyeing. Lastly, the twigs and leaves are utilised as FODDER. [*Cf. Moorcroft, Travels Himah.*, 1841, ii., 145-50; Bentham, *Rev. of Targioni-Tozzetti in Journ. Hort. Soc.*, 1855, ix., 166; De Candolle, *Orig. Cult. Plants*, 1884, 425-7; *Ind. Plants*, 1903, i., 519; CUCURBITACEÆ. The *kaddu*, *lauki*, *tumri*, *kodru*, *tikta láu*, *tumba*, *iráo*, *kundánuga*, etc. A climbing plant found wild in India, the Moluccas and Abyssinia. As a result of cultivation the fruit assumes many different forms, the best known of which are the Pilgrim's Gourd, the Bottle Gourd, the Trumpet Gourd, and the Calabash.

Fruit.

This plant is extensively grown in many parts of India for its FRUIT and succeeds best on heavily manured soil. Sowing may take place as early as February or as late as July, but for rainy-season crops two sowings are made, the first in April, the second in June. It is best to sow the seed where the plants are to grow, and about six feet should be left between each. The cultivated forms are all eaten both by Europeans and Natives. By the former, the fruit is boiled when young and used as a vegetable marrow; by the latter it is sliced and cooked in curry, or the pulp is eaten with vinegar or mixed with rice. The dried shell of the bottle-shaped gourd is used by the Natives for holding water or as oil bottles, while the small wild form, *tumri*, is used for making the stringed instrument, the *sitar*, and the wind instrument, *bin*. The seeds yield a clear,

Oil Bottles.

limpid OIL which is medicinal. The pulp of both the wild and the cultivated forms, as also the leaves, are purgative. [Cf. Asa Gray, *Scient. Papers*, 1889, i., 330-2; Basu, *Agri. Lohardaga*, 1890, pt. 1, 78-9; *Pharmacog. Ind.*, ii., 67-8; Gollan, *Ind. Veg. Gard.*, 1892, 116; Banerjee, *Agri. Cuttack*, 1893, 115; Woodrow, *Gard. in Ind.*, 1899, 331; Firminger, *Man. Gard. Ind.* (ed. Cameron), 1904, 168-9.]

LAG TR MIA, Linn.; *Fl. Br. Ind.*, ii., 575-8; Gamble, *Man. Ind. Timbs.*, 371-6; Talbot, *List Trees, etc.*, 1902, 175-6; Cooke, *Fl. Pres. Bomb.*, 1903, i., 512-4; Brandis, *Ind. Trees*, 337-40; LYTHRACEÆ. A genus of trees or shrubs containing 18 species—natives of South-East Asia. Burma may be spoken of as the centre of the genus.

L. Flos-eginæ, Retz.; *Rec. Bot. Surv. Ind.*, iii., 213. The *jarúl*, *ajhar*, *taman*, *kadali*, *adamboe*, *eikmwue*, *pyinma*, etc. "The chief timber-tree of Assam, Eastern Bengal and Chittagong, and one of the most important trees of Burma." It also occurs in Chota Nagpur, the Circars and the west coast from the South Konkan southwards. It is commonly cultivated as an avenue tree. Is chiefly found along river-banks and on low swampy ground, but occurs only sporadically.

No special care is taken to propagate the plant. It is ready to be felled when thirty to fifty years of age. The timber is used for shipbuilding, boats and canoes; for construction of carts, etc. It has also been employed for gun-carriages and was recommended for gunstocks, but the report on the experiments so far made has been unfavourable. In South India it is used for building and in Ceylon for casks. It is said to be very durable under water, but to decay soon when under ground. Hope (*Jarul Timber, Ind. For.*, 1885, xi., 373-6), however, condemns the wood as not being durable and as being too readily attacked by white ants, but Gamble remarks that it is not quite certain the wood Hope refers to was in reality that of this tree. The average weight varies from about 40 to 45 lb. per cubic foot. A report is given by Unwin (in *Imp. Inst. Tech. Repts.*, 292-3; also in *Agri. Ledg.*, 1897, No. 9, 181-3) on various mechanical tests made on a block of this timber. He gives the following results:—weight, 41.77 lb. per cubic foot; resistance to shearing along the fibres, 832.4 lb. per sq. inch; coefficient of transverse strength, 5.22 tons per sq. inch; coefficient of elasticity, 544.1 tons per sq. inch; crushing strength, 2.762 tons per sq. inch.

There appears to be no trade in this timber carried on in the provinces of India, except Assam. Of the Garo hills it is said that all the timber removed is exported to Bengal, and that the price of a standing tree is Rs. 6. In Cachar about 20,000 cubic feet are exported yearly to various places in the Sylhet district, and the price averages Rs. 1-2 per cubic foot. [Cf. Unwin, in *Ind. For.*, 1898, xxiv., 89-91; Woodrow, *Gard. in Ind.*, 1899, 318; *Agri. Ledg.*, 1902, No. 1, 43.]

L. parviflora, Roxb.; Duthie, *Fl. Upper Gang. Plain*, 1903, 353; *Rec. Bot. Surv. Ind.*, 1904, iii., 59. The *báklá*, *sida*, *dhaura*, *nana*, *bondára*, *chenangi*, *tsambelat*, *zaung bale*, etc. A large deciduous tree common almost all over India, except in very dry regions. It is of considerable economic importance since the timber is in demand for general purposes such as house-posts, beams and rafters, door and window frames, agricultural implements, carts and boats. It also yields a good charcoal. The average weight is about 53 lb. per cubic foot. The bark has been employed in tanning and as a black colouring agent. It also yields a fibre used in Chota Nagpur for ropes, and the gum is said to be sweet and edible. The tree is one of those on which the *tasar* silkworm is reared.

LA AND TALL W.—The rendered fat of the pig forms the valuable commercial product Lard. A similar substance prepared from cattle and sheep is Tallow (see Live tock, p. 754; also ils, pp. 813-4, 819). Space cannot be afforded to deal with these substances separately. Speaking of lard, the best is the so-called Leaf Lard. This is derived from the fat surrounding the kidneys, and from the flaky layers below the skin. In European trade two other qualities are prepared from the softer and more fusible parts of the fat, and are known as second and third quality lard.

Lard.—The following information regarding the manufacture in Calcutta

Two Kinds
of Pigs.

is communicated by Mr. I. H. Burkill, from information derived from Mr. S. Francis, superintendent of the pig slaughterhouse, Calcutta. Formerly lard was made by three large firms and several small houses, but lard-rendering is now carried on by a few small Native concerns only, and these are situated round the municipal pig slaughterhouse. With the disappearance of large and responsible firms, the quality of the lard has degenerated. The manufacture goes on all the year, but the beginning of the hot weather is the busiest season, because then most pigs are brought in. Two kinds of pig are slaughtered; one, bred in Calcutta, is called the "China-pig"; the other, driven in from the villages of Bengal, is called the "country pig." The former is white, the latter black. The animals are slaughtered in the early hours of the morning and lard-rendering begins in the forenoon. The rendering house consists of a small room and a larger godown, where the lard is cooled and stored. The rendering is done in an iron pan about two feet across and eight inches deep, placed over a slow fire. Scraps of fat of all shapes, but none weighing more than three or four ounces, are washed in water for about two hours and then heaped up in the pan to above the level of the rim. When the lard is thoroughly melted it is poured out of the pan through a double thickness of cotton-muslin into an earthenware vessel, where it stands to set. Several times a day during setting it is stirred gently for about half an hour. The time taken in setting varies with the nature of the animal from which the fat has been obtained. Lard from the "China pig" takes about two days to set, that from the "country pig" a much less time, and the lard is of better quality. Lard thus manufactured will keep for about two months only, but formerly for a much longer time—a circumstance due apparently to the fact that fat of the freshest and best quality is not always used.

The best quality of lard is much used in cooking and in preparing ointments, etc., the second in the manufacture of lard oil, the third as a low-grade oil in soap-making. The oil is manufactured by exposing the lard in woollen bags between wickerwork to a pressure of about ten cwt. a square inch in the cold for about eighteen hours. The oleine thus obtained is pure, colourless and limpid. It is employed as an adulterant for olive oil in France, and for sperm oil in the Eastern States of America. It is also esteemed as a lubricant and is used for illuminating. In MEDICINE, lard has long held the principal place as a medium for the exhibition of other substances, as ointments, etc. As an external application it possesses emollient properties, and is extensively employed in external inflammations, bruises, sprains, and in various skin eruptions.

Tallow, as already stated, is prepared from beef or mutton and goat fat, or a mixture of these. It is a harder and less fusible fat than lard. The rendered tallow is refined by boiling with water; is often bleached by means of nitric acid, and employed as a lubricant and for soap and candle making. When intended to make moulded tallow-candles, the finest mutton suet can alone be used, but for "dips" the refuse from the moulded candles or the cheapest tallow (a mixture of all animal fats) may be employed. Hoey (*Monog. Trade and Manuf. N. Ind.*, 174) speaks of the candle-makers of Lucknow using *charbi* (fat), but though he deals most minutely with the industries of that city, he makes no reference to the lard and tallow manufactures. So again, speaking of soap manufactures, he states that *charbi* (bullock and buffalo fat and *tel*, either castor or linseed) is employed.

BOMBAY TRADE IN TALLOW

**LATHYRU
ATIVU**

Chickling Vetch

Trade in Lard and Tallow.—The foreign traffic in LARD appears to be declining. The *EXPORTS* in 1876-7 were valued at Rs. 3,22,825; in 1886-7, Rs. 1,93,823; in 1896-7, Rs. 67,900; and for the past five years they have been:—1902-3, Rs. 52,810; 1903-4, Rs. 30,526; 1904-5, Rs. 15,500; 1905-6, Rs. 18,750; and 1906-7, Rs. 15,747. Corresponding with this change in the traffic, the *IMPORTS* may be said to manifest an expansion: in 1899 they were valued at Rs. 26,952; in 1900-1 at Rs. 47,058; and for the past five years have been:—1902-3, Rs. 61,462; 1903-4, Rs. 70,610; 1904-5, Rs. 55,454; 1905-6, Rs. 59,536; and 1906-7, Rs. 92,370. The traffic in TALLOW corresponding to the lard just given was as follows:—*EXPORTS* were in 1876-7 valued at Rs. 31,234; 1886-7, Rs. 54,097; 1896-7, Rs. 95,574; and during the five years ending 1906-7 were valued at Rs. 1,70,721, Rs. 2,17,828, Rs. 1,30,999, Rs. 1,11,255, and Rs. 80,404. Thus it may be said this export traffic is, on the whole, an expansion. The *IMPORTS* in 1876-7 were valued at Rs. 62,671, and for the past seven years have been:—1900-1, Rs. 3,46,570; 1901-2, Rs. 5,51,976; 1902-3, Rs. 3,84,402; 1903-4, Rs. 5,93,127; 1904-5, Rs. 6,80,054; 1905-6, Rs. 8,16,705; and 1906-7, Rs. 9,14,834.

Nearly the whole of the Lard exported from India goes from Bengal to Mauritius. Formerly a fair amount was consigned to Reunion and to the Straits Settlements, but for some years past both these countries have discontinued their demands. India, as shown above, imports lard, and by far the major supply comes from the Straits, and recently from China (Hongkong), but Burma may be described as the receiving province. Of the total imports in 1903-4, viz. 316,111 lb. (the largest quantity for the past five years), valued at Rs. 70,610, Burma alone took 303,727 lb., valued at Rs. 65,203. The returns of the coastwise traffic do not show lard separately from "Other Provisions," so that it is not possible to discover to what extent Bengal or the other provinces of India are competing with the Straits for a share in the Burmese market.

Speaking of the traffic in TALLOW, it is curious that while Bengal is the province most concerned in lard, the tallow traffic is concentrated chiefly in Bombay. The foreign *EXPORTS* in 1906-7 were 4,135 cwt., valued at Rs. 80,404, of which Bombay exported 3,517 cwt., valued at Rs. 69,601. Of the receiving countries, Arabia seems to manifest the most constant demand, taking 2,260 cwt. out of the total. *IMPORTS*.—A curious feature of the tallow traffic may now be mentioned, namely that Bombay, followed by Burma, takes by far the largest share of the foreign supply. During 1906-7 India imported tallow to the extent of 36,837 cwt., valued at Rs. 9,14,834, and of these amounts Bombay took 23,325 cwt., Burma 6,433 cwt. The countries of supply were the United Kingdom, 19,604 cwt., and Belgium, 6,288 cwt. There is no mention of re-exports, so that India would appear to be by no means self-supporting in its lard and tallow supplies. [*Cf. Hurst, Lubric. Oils, Fats, etc.*, 1896, 180; also *Soaps*, 1898, 119-20; Blyth, *Food Compos. and Anal.*, 1903, 310-6; Leach, *Food Inspect. and Anal.*, 1905, 451-6].

Chicklin -
Vetch.

teora, *tiura*, *churál*, *lák*h (or *lác*), *lakhóri*, *láng*, etc. An annual herb which, according to De Candolle, is indigenous to the region that extends from the Caucasus to Northern India.

Cultivation.Dry *Rabi* Crop.**Chief Areas.**

Cultivation and Area, etc.—This vetch is cultivated throughout India as a cold-weather crop, and has the reputation of germinating on land too dry for other *rabi* crops. To this fact is largely due its value agriculturally. It can take the place of other crops when the October rain has failed, and as an article of food it is remarkably cheap. Statistics of actual cultivation are not available for the whole of India, so that a complete statement of the total area cannot be furnished. The following particulars of a few provinces are, however, instructive. In 1904-5 the CENTRAL PROVINCES had an area of 363,504 acres, chiefly in Nagpur (163,632 acres) and Chhattisgarh (152,046 acres) districts. BERAR appears to have had 14,408 acres. BOMBAY (excluding Sind) 18,656 acres, mainly in Broach. SIND by itself had 232,070 acres, chiefly in Larkhana district (142,014 acres). The UNITED PROVINCES do not appear to have published the area recently, but some few years ago the acreage devoted to the crop was said to have been 56,100 acres. No returns of any kind are available for Bengal, Assam, Burma, the Panjáb, Rajputana and Central India, nor Madras. There is no evidence, however, that these provinces materially affect the total Indian production. The two chief areas are the Central Provinces and Sind.

Tillage.**Soils.****Season.****Seed.****Cost.****Fodder.****Food.****Paralysis and Lathyris**

Tillage and Yield.—To give some conception of the methods of cultivation, yield, etc., of this pulse, the admirable account given by Mollison (*Textbook Ind. Agri.*, 1901, ii., 29; iii., 78-80) may be here drawn upon. *Láng*, he says, is almost invariably grown alone, though a slight admixture may be found in gram (*Cicer arietinum*) fields. It thrives best on deep, retentive, black soils. In the Deccan it is chiefly a second crop in rice-fields, but in Gujarat it is the sole crop of the year. In Broach it is generally raised on low-lying fields liable to be flooded by heavy rain, all fields which become waterlogged and too wet for cotton being commonly sown with *láng*. Tillage operations begin by ploughing after the first fall of rain. If the rains are unfavourable for cotton, the field is kept for *láng* and repeatedly harrowed during July, August and September. No manure is applied, but the ground is carefully prepared, since *láng* grown on clean ground is a good preparation for cotton in the succeeding year. Sowing takes place in September or early in October, and the seed-rate varies from 35 to 40 lb. per acre. The seed is dropped in the plough furrows in rows about a foot apart, and the surface levelled and pressed immediately after. No weeding is required, and the crop ripens in February about four and a half months after sowing. It is reaped before it is fully ripe, formed into small heaps in the field, and allowed to dry for a week. When dry it is threshed out under the feet of bullocks and winnowed in the ordinary way. The cost of cultivation is stated to be Rs. 13-12 per acre. In a well-grown crop the weight of pulse almost equals the weight of fodder. From full average crops in Broach, Mollison found the outturn of pulse to vary from 925 lb. to 1,068 lb. per acre, and of fodder from 1,220 lb. to 1,405 lb. *Láng* is cultivated chiefly as a FODDER, but as it is cheap and easily grown, it is considerably used as FOOD by the poorer classes, principally in the form of bread, *dál*, or porridge.

Evil Reputation.—Much interest has been, for a century or more, spasmodically directed to this pulse, on account of its evil reputation of causing paralysis

LATHYRISM

of the lower extremities, when eaten continuously for any length of time. But it might be said that the whole family of LEGUMINOSÆ, much as we use them, are in some respects a suspicious family. A few years ago I gave attention to this particular pulse, and in consequence placed before the members of the Medical Congress of Calcutta (1894) the results of my inquiry. I then pointed out that it exists in two sizes, the smaller form being known in Chhattisgarh as *lakhori* and the larger in Nagpur and Bhandara as *lakh*. The former is sown earlier than the latter. Its seeds are broadcasted over the flooded rice-fields (towards the close of the rains), while the latter is sown on rich black, dry soils, on land ordinarily devoted to wheat. The opinion seemed universal that while the *lakhori* or rice-field cultivation yielded a harmless seed, the *lakh* or wheat-field crop was very dangerous. There would appear to be no botanical characteristics to account for this remarkable difference.

Speaking on the dangerous property of this pulse, Major A. Buchanan, I.M.S., who has given the subject much careful study (*Lathyrism Rept.*, 1904, 25), says, "Continued growth of rice-land *teora* on rice land has produced a different race. At any rate it is easy as a rule to distinguish a heap of *lakh* from a heap of *lakhori*, but there might be a difficulty in distinguishing single seeds of the two kinds. The wheat-land *teora* or *lakh* is as a rule larger." "The weights of a hundred seeds of *lakh* varied between 245 and 110 grains, the weights of *lakhori* varied between 108 and 77 grains. The colour of the wheat-land *teora* is darker than the colour of the rice-land *teora*. The latter is called the yellow *latri* in Azamgarh." In that district the people consider that the yellow *latri* is non-poisonous, and the people of Bhandara have for many years held the same opinion. For our present purpose it may, therefore, suffice to thus indicate the two crops met with in India.

Properties of the Pulse.—Sir J. B. Fuller, while Commissioner of Jabbalpur, suggested that the greater care taken by the people of Chhattisgarh in cooking this grain might account for their partial immunity from toxic action. The grain, he explained, is in Raipur commonly parched before being ground, and the husk of the grain is, moreover, separated and not eaten. This causes a loss of 25 per cent. in the weight—a loss which those in poverty are naturally averse to sustaining. The flour thus prepared is next baked into cakes (*chapattis*), or boiled with buttermilk into a paste known as *mahera*. This suggestion led to the supposition that the poison might consist of some volatile substance expelled by the dry heat, or that it resided in the husk. Mr. Cleveland suggested that *tiura* loses its poisonous qualities when eaten along with *mahua* (the flowers of *Bassia latifolia*). So also many years ago Dr. Kinloch Kirk pointed out that rice to be completely wholesome must be kept for some time. The best rice is three years old. Rice under-kept boils thick and becomes gummy, and is not wholesome. Hence it has been argued that the age of the *lakh* grain may similarly have something to say to its poisonous property.

The following chemical analysis of the pulse is given by Church (*l.c.*, suppl., 13):—water 11.1, albuminoids 24.4, starch, etc. 55.3, oil 1.0, fibre 5.4, ash 2.8. The nutrient ratio is here 1 : 2.3 and the nutrient value 82.

Lathyrism.—Mention has already been made of the fact that it has for long been known that a form of paralysis, to which the name *Lathyrism* has been applied, is believed to result when this pulse is eaten continuously for some length of time. One peculiarity of the disease (in men) is that it affects adult males chiefly (1 in 10). Another, that it is the lower extremities that become paralysed. But similar results are produced when the pulse is given to horses, cattle, pigs. Investigations have been conducted at the Imperial Institute with a view to ascertain the nature of the poison, but the results so far attained have been entirely negative. The poisonous property, we are assured, is not due (as has been supposed) to a volatile alkaloid that might be dissipated by superior methods of cooking, nor to any ordinary chemical poison. Dunstan has very properly pointed out that it is by no means certain that the seeds sent to Europe for examination were actually those of the poisonous sort. But it may have been inferred from the observations already made that we have no simple method by which to ascertain when the seeds are or are not poisonous, and can but procure supplies from localities where the paralysis mentioned prevails. In no instance does the poison exist in such abundance as to give immediate indication of its presence. It is only after protracted consumption that the paralysis appears. In fact there would even seem grounds for suspecting that the plant may only be intermittently poisonous, so that no particular race or crop could be

pointed out as *the* poisonous seed. The subject has been approached at the instance of the Imperial Institute from another point of view, namely investigations to ascertain if the pulse possesses a poisonous fungal parasite that could account for the toxic action. Prof. Percival, of the Wye Agricultural College, failed to discover any such fungus.

General
Conclusions.

Recently the disease has been very prevalent in the Central Provinces, and a census showed that the number of people more or less paralysed was over 7,600. In view of this fact Major Buchanan was put on special duty to inquire into the cause of the spread of lathyrism, and to endeavour to find means for its prevention. The results of his investigations are embodied in a bulky report (to which reference has already been made). He gives the following general summary:—"It has been shown that lathyrism is due to the consumption of *Lathyrus*; that the disease, when it occurs in big epidemics, follows famine or scarcity; that it is chiefly confined to wheat-growing areas; that failure in wheat is an important factor in the causation; that the disease is chiefly found among the poor, and that debt is an important factor in the causation. Under certain circumstances *Lathyrus* is a good article of diet, and it is only when the proportion reaches or exceeds one-half of the whole ration that paralysis is likely to occur." On the other hand, Dr. A. G. Hendley (*Brit. Med. Journ.*, 1903, ii., 707-9), after discussing fully this subject, arrives at the conclusion that "*Lathyrus*, whilst it may possibly cause paralysis by itself, ordinarily only predisposes to it, that it makes the subject ready or ripe for the attack of paralysis, but that exposure to severe wet and cold is required actually to excite the sudden seizure." "The attack occurs after an unusually thorough wetting whilst ploughing, watching crops at night or other field work that ordinarily falls to man's lot and not woman's."

Predisposes to
Paralysis.

Trade

Trade.—No particulars can be furnished of the trade in this pulse. It is known to be occasionally exported. Some few years ago a sample of what was called "*mútar*, or Indian Grey Peas" was shown to me by a Glasgow corn-merchant. I pointed out that while this pulse was occasionally called *mattar*, the true *mattar* of India was the Grey or Field Pea. It is, therefore, most important that the present pulse should not be confused with the grey pea of India, which is as harmless and useful as the grey pea of Europe. The wedge-shaped pea of the present plant, flattened on two sides and marbled on the surface, should easily be distinguishable from all the peas or pulses of India, except perhaps gram (*Cicer arietinum*); but while gram is somewhat triangular in section it is prominently tapered below into a beak, and is devoid of the marbling of *Lathyrus*.

Confused with
Grey Peas.

Cultiva-
tion.

Cultivated throughout India on account of its LEAVES, which yield the "henna," dye and also as a garden hedge plant. The soil is repeatedly ploughed and heavily manured, and the seed is soaked in water for twenty-five days before sowing, which takes place in April and May. The plot of l d where the seeds are to be sown is formed into beds and kept flooded for some days. The seed is scattered on the water and sinks with it into the ground. For three days water is given both night and morning; after that only once a day till the plants

appe above ground, when they are watered every alternate day. When about 2 feet high they are ready for transplanting in July and August. About 6 inches are nipped from the centre shoot, and the young plants are then put singly into holes one foot apart. They are watered daily till they have recovered the shock of transplanting, and the fields are weeded once a month. No crop is reaped the first year, but afterwards two crops a year are obtained, one in April-May, the other in October-November, for many years on end. At each cutting about 9 inches are taken from the top shoots, and an acre yields about 20 maunds of dry leaves a year.

Transplanting.

Cropping.
Season.

The DYE is obtained from the leaves: these are dried, sifted, a little sarson oil added, then reduced to a powder. This powder may be purchased at all the cosmetic and dye shops in the larger towns of India, and may be seen in small sacks alongside of the imported aniline dyes. It is occasionally used in dyeing cloth, but its principal value in India is as an article of the toilet, for staining the finger-nails, hands and feet a dull orange colour, also for dyeing the hair into a bright red colour, what is often but a first stage in the production of black by the action of indigo on the original red. The use of *henna* as a cosmetic dates from very ancient times, and is universal among Muhammadan women, and to a greater or lesser extent among Hindus also. The seeds yield an OIL about which little is known, and the flowers are employed in perfumery and embalming. [Cf. *Pharmacog. Ind.*, 1891, ii., 41-4; *Gaz. Shahpur Dist. Pb.*, 1897, 172-3; Woodrow, *Gard. in Ind.*, 1899, 319; Firminger, *Man. Gard. Ind.* (ed Cameron), 1904, 565.]

L AD d it lts d uf eture.—Ball, *Man. Econ. Geol. Ind.*, 1881, iii., 281-311; King and Pope, *Gold, Copper, Lead in Chota Nagpur*, 1891, 95-9, 156, 159-69; *Rec. Geol. Surv. Ind.*, 1904, xxxi., pt. 1, 46-7; Holland, *Rev. Min. Prod. Ind.*, in *Rec. Geol. Surv. Ind.*, 1905, xxxii., pt. 1, 110. This metal bears among other names the following:—*sisa*, *búndi*, *surb*, *ikam*, *te aétam*, *khai-pok*, etc. It rarely occurs anywhere in the native state, and never found in that condition in India. Its commonest ore is the Sulphide or Galena, *surma*, *anjana*. Other common ores and salts are:—Red Oxide of Lead, *sandhur*, *segapú*, *temaméra*, *h'sang*, etc.; Litharge, *murdasang*, *marudar singhie*; Carbonate of Lead, *saféda*, *vullay*, *sibaydú*, etc.; Chromate of Lead, *peori-wilayti* (= English *peori*, see p. 765).

D.E.P.,
iv., 60 -5.
Lead.

Mining.—Although lead ores have been worked to some extent in ancient times, at the present day lead-mining in India is practically in a dormant condition. Holland makes the following statement with regard to it:—"Galena alone, or with blende and other sulphide ores, is known in various parts of India and Burma, and has been worked in various places for lead or lead and silver, under past Native rulers; but the mining of lead-ores has long been extinct, and the only recent attempt calling for special mention is that now being made to develop the deposits near Pang Yung in the Northe Shan States formerly worked by the Chinese, who left behind large heaps of slag reported to be amenable to profitable treatment by modern metallurgical processes for the extraction of silver."

Mining.

Manufactures.—The metal is comparatively little employed by the Natives of India, owing to its scarceness. It is, however, occasionally used in the manufacture of certain wares and alloys, as for example in Hyderabad and Lucknow, where it is a component of the alloy of which *Bidri* ware is made (Watt, *Ind. Art at Delhi*, 1903, 47). Both the red oxide of lead and the carbonate or white lead are commonly utilised as pigments, e.g. in lac turnery (Watt, *l.c.* 211-2, 231), in Afridi waxcloth (*Agri. Ledg.*, 1901, No. 12, 400 *et seq.*). Red oxide is largely employed for religious purposes by the Hindus, who mark their idols and their money with it. All married Hindu women employ it as a paint to give a circular spot on the forehead. In MEDICINE, the monoxide or litharge, the carbonate, acetate, sub-acetate, nitrate and iodide are all official in the Indian Pharmacopoeia. All these salts, except the acetate, are applied externally only, as sedative and cooling astringents, in various skin diseases. The acetate is similarly used, but is also administered internally.

Medicine.

Trade.—The I ORTS of lead from foreign countries e very considerable; Imports.

Sheet Lead for
Tea Chests.

in 1906-7, 102,455 cwt., valued at Rs. 15,82,550. In addition, Government imported 12,301 cwt., valued at Rs. 1,58,840. The greater part of these imports came from the United Kingdom. But it has to be pointed out that the chief market is the supply of the tea industry with the sheet lead required for lining tea chests, which is admitted free of duty. This came in 1905-6 to 82,166 cwt., valued at Rs. 11,23,738, and in 1906-7, 57,307 cwt., valued at Rs. 8,76,730, and was consigned from the United Kingdom almost entirely to Bengal. In the year 1906-7 the chief sources of supply for lead of all kinds were as follows:—United Kingdom, 76,230 cwt.; Australia, 16,001; France, 4,139; Belgium, 2,090; Ceylon, 2,864. The share of the Presidencies and Provinces in the imports were:—Bengal, 72,548 cwt.; Bombay, 10,772; Madras, 6,197; Sind, 4,918; Burma, 3,493.

Exports.

The Export trade in Indian merchandise is a negligible quantity, but a fair re-export trade exists. Thus in 1906-7 it amounted to 5,293 cwt., valued at Rs. 46,402. The bulk of this re-export traffic goes from Bombay, chiefly to the United Kingdom, Arabia, Persia and Turkey-in-Asia. [Cf. Tavernier, *Travels* (ed. Ball), 1889, ii., 281, 284; Masson, *Journ. to Kalat*, 1843, 462; *Minerals, Offic. Correspond. Rev. and Agri. Dept. Govt. Ind. (Proc.)*, Dec. 1892; *Rev. Min. Prod. Lentil.

L N E CUL NTA, Moench.; Duthie, *Fl. Upper Gang. Plain*, 1903, 257; Prain, *Beng. Pl.*, 1903, i., 367; *Ervum Lens*, Duthie & Fuller, *Field and Garden Crops*, 1883, ii., 13, t. xxx.; *Fl. Br. Ind.*, ii., 179; LEGUMINOSÆ. The Lentil, *masúr*, *channangi*, *mohr*, *chanching*, *kerze*, *adah*, *misurpurpur*, *misur-pappu*, etc. A valuable pulse, grown as a winter crop all over India. According to De Candolle, it is a native of western temperate Asia, Greece and Italy, and has long been cultivated in Egypt, whence it was conveyed to India. As an article of food it has been known from the most ancient times.

Cultiva-
tion.

Cultivation.—At the present day the lentil is cultivated in all parts of India, especially in the Central Provinces, Madras and United Provinces. The following is a brief summary of the area under cultivation and the methods pursued in those provinces about which trustworthy information can be obtained.

Bengal.

Bengal.—Separate returns for this pulse are not recorded, hence an estimate of the area under cultivation cannot be given. It thrives best on a clay soil, since in light soils the plants wither away. In rotation following paddy (rice), the land receives three or four ploughings and the seed of the lentil is then sown October to December at the rate of about 5 seers per *bigha* (= one-third acre). In some parts of the country it is mixed with barley. Harvesting takes place from the middle of February to the middle of April; the crop yields about 8 maunds per acre. The cost of cultivation has been estimated at Rs. 2-10 per acre. [Cf. Basu, *Agri. Lohardaga*, 1890, pt. ii., 34; Banerjee, *Agri. Cuttack*, 1893, 83.]

Assam.

Assam.—Cultivation is chiefly confined to the *chaparis* of Kamrup, Nowgong and Mangaldai. In Upper Assam it is cultivated to a small extent in the Majuli. The crop prefers a light, loamy soil and an open situation, and generally follows a broadcasted *áhu* (rice) crop, and is sown in mixture with mustard. Sowing takes place within the first fortnight of November. The seed rate is 12 lb. per acre, if sown with mustard, but if sown alone, about 50 per cent. more seed is required. Harvesting takes place in March and April, and the usual yield is about 2 to 4 maunds per acre. [Cf. *Agri. Dept. Assam Bull.*, 1902, No. 9, 11.]

Seasons.

Crop.

U. Prov.
Area.

United Provinces.—The area under *m úr* is not separately recorded, but in 1904-5 peas and *masúr* together occupied an area of 2,055,879 acres, distributed thus:—1,437,152 acres in Agra, 618,727 acres in Oudh. According

to Duthie and Fuller, cultivation is most extensive in the damper parts of these provinces. It is sown in all kinds of soil, but chiefly in low-lying land. Generally it follows early rice, being often sown while the rice stalks are standing, and is allowed to grow up amongst them. The seed rate varies with the condition of the ground, but is commonly about one maund per acre. The outturn from unirrigated land varies from $6\frac{1}{2}$ to 8 maunds per acre, but with irrigation may reach 10 to 12 maunds.

Central Provinces and Berar.—In 1904-5 the area under the crop was in the Central Provinces, 231,756 acres, chiefly in the Chhattisgarh, Jabbalpur and Nerbudda Divisions, and in Berar, 13,167 acres. It is generally sown on the best black soil.

Panjáb.—No statistics of area are available. In the Jhang district, which is typical of the province as a whole, it is a *sailaba* or inundation crop. New alluvial soils or light lands, not good enough for wheat, are selected. The land is ploughed once or twice and the seed is sown broadcast, 30 to 45 lb. per acre, from December to January. The crop is ripe in March to April. [*Cf. Gaz. Panjáb Dist.*]

Bombay.—In 1904-5 the area was 9,791 acres, chiefly in Násik (5,097 acres) and Belgaum (2,918 acres). *Masúr* is always an unirrigated *rabi* crop, and generally is grown alone. In Poona it is the sole crop of the year, and is rotated with dry-crop wheat. The soil is mixed black, but only of moderate depth. In September and October the land is repeatedly ploughed, and in October the seed is drilled in rows a foot apart at the rate of 20 to 25 lb. per acre. The crop ripens in three and a half months, and a good outturn is about 300 lb. per acre. [*Cf. Mollison, Textbook Ind. Agri., 1901, iii., 89-90.*]

Food.—In India it is eaten as *dál*, flavoured with various aromatics and condiments, also as a component part of the dish called *kichri*, and is considered the most nutritious of the pulses. The young pod is also eaten as a vegetable, and the dry leaves and stalks are greatly prized as fodder. In Europe this pulse meal, mixed with barley flour or other cereal and common salt, is sold as an invalid food under the name *ERVALENTA* or *REVALENTA*. Leather (*Ind. Food-Grains and Fodders, Agri. Ledg., 1901, No. 10, 366*) gives the following **CHEMICAL** analysis:—moisture 8.03 per cent., oil 1.06, albuminoids 23.0, soluble carbohydrates 61.14, woody fibre 2.42, soluble mineral matter 3.54, sand and silica 0.81, total nitrogen 3.94, albuminoid nitrogen 3.68. As a **MEDICINE**, lentils have long had the reputation of being useful in cases of constipation and other intestinal affections.

[*Cf. Benthams, Rev. of Targioni-Tozzetti, in Journ. Hort. Soc., 1855, ix., 139; De Candolle, Orig. Cult. Plants, 1884, 321; Church, Food-Grains of Ind., 1886, 138-9; Asa Gray, Scient. Papers, 1889, i., 347; Kanny Lall Dey, Indig. Drugs of Ind., 1896, 174-5; Yearbook of Pharmacy, 1898, 77.*]

LI, AR L, CHALK, etc., or C lei d its It D. P.,
d M n f ctur .—Although *Lime* (Calcium) does not exist in a pure state, in the form of the carbonate it constitutes a by no means insignificant portion of the earth's crust, e.g. limestone rocks. *Lime-burning* is the operation of driving off carbonic acid from the carbonate with the production of the oxide of calcium or *Quicklime*. This readily absorbs water and becomes *Slaked Lime* or hydrate of lime (*Agri. Ledg., 1902, No. 5, 137-47*). The subject may, therefore, be dealt with under two great sections—**C lei u C rbo te** and **C lei m l h te**.
LI ME, CARBONATE OF.—This is known in India by an extensive series of vernacular names that denote the conditions (quick-lime, slaked lime, etc.) and the sources (limestone, marble, chalk, shells, etc.). The most general name is perhaps the Hindustani *chuná*, a word which in the various languages of India assumes numerous forms, such as *chúnáh, chún, chúnó, chúnak, chúnambu, chúrna, shunnambu, sunnam,*

Indian Names.

sunna, hunna, hunu, etc. Its most general name in Sanskrit would appear to be *sankha-bhasma*, but certain writers give also *churná* (= a "powder"), *sudha, kapardaka-bhasma, sukti-bhasma*, etc. Its Arabic names appear to be *kils* and *ahu* and its Persian *nurkah* and *ahak*. CHALK is very generally known as *khari-matti* or *kharya-mitti*. UNSLAKED or QUICKLIME is *kali-ka-chuna* or simply *kali* or *kalai*, often also called *ahak*; LIMESTONE is *kalai-ka-pattar*; SHELL LIME is *sipi-ka-chuna*; the lime from LIMESTONE LIME being *kattal-ka-chuna*; MARBLE is *marmar*; FOSSIL CORALS are *sang-i-yahada*.

Chinám.

The word *chinám*, by modern usage, generally denotes, however, the beautiful plaster or cement characteristic of many localities of India, more especially in the south (see below in the paragraph devoted to *ortar* and *Cements*, p. 713). One of the earliest European writers to use the word *chuna* appears to be Garcia de Orta (A.D. 1563), although fifty years previously the Italian traveller Varthema describes the people around Calicut as eating betel leaves along with a certain lime made from oyster shells, which they call "*cionama*."

Sources.—There may, in India, be said to be three great groups of rocks or materials that afford lime, as follows :—

Lime-stones.

(a) *Limestone, Dolomite, Miliolite, etc. (Imp. Gaz., iii, 148-50).*—Hardly any known geological formation in India is wholly without limestone in some form, although many of the examples are exceedingly impure and scarcely worthy of the name. Mr. R. L. Sevenoakes, in the *Journal of the Queen Victoria Indian Memorial Fund* (No. 2, 26-31) (a publication here utilised freely), describes some twenty different kinds of Ornamental Building Stones. Some Indian ornamental stones are of nearly equal merit to the marbles specialised below, and still others gradually decline until they have to be characterised as at most only good building limestones. The limestones procurable in many parts of Bombay and Sind, for example, are admirable building stones, though marble nowhere exists in that Presidency. The Porbandar miliolite (foraminiferous limestones) has been conveyed from Kathiawar to Bombay and even to Calcutta, and is employed in the construction of some of the more important of the recent buildings of these cities. In South India it may be said that crystalline limestones occur in Trichinopoly and Coimbatore, but of very inferior quality; good building limestones are found in Cuddapah, Karnul and Guntur, and marbles at Palnad. In the Central Provinces there are numerous examples of limestones and admirable building stones, such as those of Wardha, Nagpur, of the Vindhyan formation, such as the limestones of Katni; and in the United Provinces the crystalline limestone of Mirzapur, which occurs in the metamorphic rocks of that district. In various localities of the Panjáb good limestones and even marbles are found. Lastly a reference is essential to the limestones of Lakhimpur and of the Khasia and Jaintia hills of Assam.

Lime.
Satná.

The most important sources of limestone and lime may thus be grouped commercially :—

"1. *SATNÁ* in Rewah and at Katni, in the Jabbalpur district. From both localities lime of excellent quality is carried as far as Calcutta (624 and 685 miles distant), and constitutes a large proportion of the lime used in that city. 2. *SYLHET*.—Along the southern foot of the Khasia and Jaintia hills there is an inexhaustible supply of nummulitic limestone, which formerly supplied the whole of the demand of Calcutta and Lower Bengal,

Sylhet.

and still does so to a large extent. The returns of 1904 show a supply of 123,108 tons of lime, valued at £9,496. 3. *RHOTASGARH*.—The lower Vindhyan limestone near Rhotasgarh is quarried to a small extent, and exported down the Són in boats; it was largely used in the works of the Són Canal. Good lime is made from the deposits at Bisra, in the Singbhum district, and has recently begun to arrive in Calcutta in increasing quantity. 4. *HIMALAYA*.—Along the foot of the Himalaya, boulders of limestone are collected and burnt in large quantities every year; the slaked lime is exported on camels and supplies a large portion of the Panjáb and the United Provinces. 5. *ANDAMAN*.—There is a band of cream-coloured marble near Port Blair which may prove of economic importance, as it is about the same distance from Calcutta as Katni, and the lime is of equally good quality. 6. *OTHER LOCALITIES* where limestone is known are numerous, but at present of merely local importance, or in most cases of no value whatever. A full list of them as far as they are known will be found in the *Manual of the Geology of India* (1881, iii., 449 *et seq.*). ”

(b) *Lime, Concretionary or Kankar*; *Imp. Gaz., l.c.* 23.—Medlicott explained the formation of this substance as due to the evaporation of the ground water, containing in solution more or less of carbonate of lime, produced in the slow process of soil-formation by the general decomposition of rock particles. Its production is, however, very much a matter of climate, *i.e.* alternating periods of extreme moisture and dryness. In the vast majority of cases a layer of *kankar* (a word which means simply nodular stone) will be found to underlie *úsar* soils. This circumstance has been purposely only incidentally alluded to in the passages that deal with *réh* efflorescence (p. 52), because, although doubtless formed by the same physical processes, *réh* and lime have not been shown to be dependent on each other. *Réh* efflorescence may occur without any formation of *kankar*, and conversely *kankar* may exist within the soil without any evidence of *réh* efflorescence or even of an abnormal deposition of soluble alkalis.

Kankar is the chief source of lime in Upper India, and it yields an excellent and somewhat hydraulic cement. Holland (*Rev. Min. Prod., l.c.* 1898–1903, 102) speaks of *kankar* and laterite as “about the most valuable assets in building material possessed by the country.” James Cleghorn (*Ind. and East. Engin.*, June 1898, 356–7) gives the results of his study of this substance and of its practical utilisation as mortar. Very often the nodules of *kankar* are so abundant, at certain depths below the surface of the ground, that they become consolidated into blocks. Such blocks when obtainable are largely employed for building purposes, and were so used extensively in the Ganges Canal Works. *Kankar*, broken and hammered while water is poured over, is the material mainly used for road-making in the greater part of India. This circumstance gives at once a vivid conception of the abundance and extensive distribution of the substance. *Kankar* has been tried as a flux for iron on several occasions, but with very indifferent results. Its composition is too variable and its liability to adulteration too great to admit of its use, except where limestones are not available. “Large quantities of lime are made in various parts of India from highly calcareous surface soil.” “This lime when mixed with proper proportions of sand makes most excellent mortar.” (*Rept. Chief Insp. of Min in Ind.,* 1904, 4.)

(c) *Lime, Shell and Coral*.—All over India shells are burned for lime. Away in the interior of the country, wherever annual inundation occurs, a marvellous crop of exceptionally large land shells furnishes an abundant supply for most local necessities. In the Murshidabad district, for example, the following shells are so employed :—*Unio marginalis*, *U. flavidens* and *Ampullaria globosa*. On the coast tracts of India and Burma, immense beds of marine shells and of raised coral reefs are met with (see p. 989). Holland (*l.c.* 1904, 21) says that “the returns of various districts in Burma show a production of 67,461 tons valued at £11,852.” These deposits, wherever met with, are regularly utilised as sources of lime, and in South India have mainly given birth to the prosperous industry of Portland Cement manufacture—an industry that is likely to be very shortly organised near the mouth of the Ganges, where rich beds of marine shells are abundant, and may be used to supplement the Sylhet limestones. Hooper (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1904–5, 32) observes that while the proportion of lime in limestone and *kankar* is variable that of shells preserves a uniform high average. A sample of stone-lime examined contained 55·3, while a specimen of shell-lime gave comparatively 96·9 calcium carbonate.

Industrial Uses of Lime, Limestone and Marble.—Lime is universally present in the ash of all plants. As a manure, therefore, it plays an important part, especially for soils rich in organic matter. [*Cf. Trop. Agrist.*, 1906, xxvi., 70–5, 180–8.] It hastens decomposition of both animal and vegetable matter. In the form of chloride of lime (bleaching powder) it was at one time largely utilised as a disinfectant, but has been considerably displaced by more effectual and less objectionable substances such as carbolic acid. As a bleaching reagent chloride of lime is extensively employed, such, for example, as in the raising of metallic colours, in discharging Turkey reds, and in calico-printing, etc. In India lime is made into a resist paste with ordinary gum-arabic, and in that form is utilised by the calico-printer. Lime, in some form, is in fact very generally used in the dyeing and tanning industries. It is, for example, nearly universally employed by the Native manufacturers of indigo. [*Cf. Monographs, Dyes and Dyeing* :—*Assam*, 4 ; *U. Prov.*, 84 ; *Bombay*, 24, 30, 34, 37 ; *Madras*, 4.] Along with sugar it is added to the dyer’s indigo vat in order to assist in the production of white indigo. Calcium carbonate is employed as an oil paint for indoor work, and as a water colour mixed with gelatine. The Afridi waxcloth workers (see Carthaus, p. 282) add lime to their *rogban* to reduce its liquid condition and make it dry readily. The tanner utilises it to remove the hair from hides. [*Cf. Monographs, Tanning and Working in Leather* :—*U. Prov.*, 7, 9 ; *Madras*, 12, 30–4 ; *Bombay*, 15 ; *Bengal*, 10–11 ; *C. Prov.*, 68.] Lime was formerly of the greatest importance to both the soap and the candle makers (in the saponification of the fats), though in Europe to-day they mostly purchase a prepared alkali. Lastly, limestone is necessary as a flux in iron-smelting. [*Cf. Blount and Bloxam, Chem. for Engin. and Manuf.*, 252 ; Alder Wright, *Oils, Fats, Wages, etc.*]

Food and Medicine.—As an article of (what might be called) food, it is largely used by the people of India. In other words, it is an essential ingredient in the preparation known as *pán*. The lime obtained from shells is objected to, however, for that purpose, by certain Hindus, on the ground that it is derived from animals. It is used in the defecation of the saccharine juices (see pp. 929, 954). The coagulation of the nitro-

genous matter by boiling is less perfectly accomplished in the case of beet than of cane juice. The addition of slaked lime accordingly greatly facilitates that result by the formation of insoluble lime compounds. For MEDICINAL purposes, lime enjoys a well-recognised position, more especially as the basis of the mild antacid known as "lime water." [Cf. Waring, *Baz. Med.*, 1897, 90-4; Barry, *Legal Med.*, 1902, 389, 451.]

Medicine.

Mortar and Cements.—By far the most important use of lime is as mortar—a cement which consists of lime, sand and water (see pp. 292-3, 695). If lime be mixed with water, a paste is formed that will rapidly harden or "set," as it is called. When dry it will, however, be found to crack and crumble to pieces. To prevent this it is mixed with sand (or in India with the fine powder made from brick known as *surkhi*). To obviate a too rapid evaporation of water from the mortar, it is customary to moisten the stones or bricks, when a much more durable cement is the result. If mortar be properly prepared, a thin layer is found sufficient to bind together the materials with which it is mixed.

D. P.,
ii., 245
Cement.Sand and
Surkhi.

Stein (*Ancient Khotan*, 1907) describes the stucco used in plastering the surfaces of walls made of wood, mud, and (sun-dried) bricks in buildings uncovered by him from the sand with which they had been engulfed during the 3rd to the 8th centuries. The stuccoed surfaces were found to have been frescoed very elaborately and beautifully, and in many cases statues made of mud were found to have been coated with stucco and subsequently painted. In a further paragraph reference will again be made to Stein's discoveries in connection with plaster of Paris (see p. 718). It would thus seem fairly certain that an advanced knowledge existed in Eastern Turkestan of certain uses of lime long before that material came into use as a cement in stone and brick construction. The oldest constructive buildings in India, such as the Chulikyan temples of the Deccan, have the stones so fitted into each other or are of such massive blocks that they have remained in their positions for centuries without cement of any kind having been used. It seems thus fairly certain that the use of cement in house-building was subsequent to the date of the temples named. [Cf. *Papers Relat. to Magnesia Cement*, *Mad. Govt.*, 1826-37; Butler, *Port. Cement*, 1899.]

Ancient Stucco.

Ancient Temples.

There are commonly said to be the following classes of cements:—(a) calcareous; (b) gelatinous; (c) glutinous; (d) resinous; (e) mixed materials but non-resinous. The first mentioned are those with which the present article is more immediately concerned, such, for example, as the mortar already indicated. A hydraulic cement, or Portland cement as it is called, is in other words a cement which has the property of setting under water. This is obtainable from certain limestones that naturally contain from 10 to 25 per cent. of alumina, magnesia and silica, or may be artificially manufactured by mixing 65 to 80 parts of chalk or other pure lime with 20 to 35 parts of river mud or clay and a little oxide of iron, say 3 to 14 per cent. These ingredients are thoroughly mixed in water, dried slowly, calcined, and then reduced to a powder. In India, Portland cement is at present mainly manufactured in the Madras Presidency, and more recently works have been started in Bengal, but in other provinces it is occasionally prepared, and chiefly from argillaceous *kankar* to which a certain proportion of fat limestone is added. But it is a striking peculiarity of these hydraulic cements that

Classifica-
tion.Hydraulic
Portland.

Madras.

Stucco. their adhesive power is diminished by mixture with sand. When used as a stucco the sand employed must be perfectly free from loam, and the surface must not be painted over (if that be so desired) until the cement has been thoroughly dry for some months.

White Mortar. It may further be added that if Portland cements have more than 4 per cent. magnesia they rapidly decompose when kept under water. A cement with a basis of white magnesia in place of clay is sometimes known as "White Mortar." There are large deposits of magnesite and of magnesium limestones (dolomites), especially near Salem in South India, and these it is understood have recently been taken advantage of by the Madras Portland Cement Company in the preparation of a cheap, easily applied and rapidly drying plaster that takes a fine polish. In the public press it is not uncommon to read the certificates of "Arbuthnot's Portland Cement" as being "equal to the best-known brands of English Portland Cement." Mr. C. S. Middlemiss wrote in 1896 a most interesting report on the magnesite areas of the Chalk Hills near Salem (*Agri. Ledg.*, 1896, No. 15). Papers written by James Cleghorn (*Ind. and East. Engin.*, May 1894, 320-1; 1898, ii., 210-11; iii., 32-3; iv., 28, etc.) will also be found to contain much useful information regarding magnesian cements. [*Cf.* Blount and Bloxam, *Chem. for Engin. and Manuf.*, 1900, 132-42; *Min. Indust. in U.S.A.*, 1900, 75, 82; Gilmore, *Hydr. Cements*, 1-334, etc.]

Chúnám. *Chúnám*.—Incidental mention has already been made of the fact that an admirable polishing and exceedingly strong cement (sometimes spoken of as *chúnám*) is made in several parts of India. There are various methods of preparing this substance, but these all practically agree in the circumstance that some saccharine substance is combined with the lime as well as powdered marble, plaster of Paris or steatite. The sugar most commonly employed for this purpose is the *jaggery* obtained from the cocoanut palm. The milk of that palm is also mixed with lime in the preparation of a very superior whitewash. It is believed that the sugar promotes the solubility of the lime, thus allowing of a finer and more complete state of division.

Carved Cement. A special art of some parts of India, as, for example, in Bikanir, consists in carving cemented surfaces into rich floral designs that may be subsequently gilded or painted. [*Cf. Ind. Art at Delhi*, 1903, 95-6.]

Glutinous Cements. *Cement Materials*.—Lime or some of its salts (such as plaster of Paris) is largely employed in combination with glutinous and resinous materials in the formation of cements. The rice-water is in India commonly mixed with a certain percentage of pure lime in the preparation of a strong cement which is employed to join the various parts of musical instruments in place of glue. Instead of rice, the dough of fine flour may be kneaded in water until gluten only remains. To this should then be added a small quantity of pure lime. The cement thus prepared is largely used for all forms of woodwork, and has the special merit of resisting damp. It is generally known by the name *súji*. Lac combined with borax forms a convenient cement to be used where exposure to water or moisture is unavoidable. Cutlers' cement consists of rosin, bees'-wax and brickdust and plaster of Paris, or simply rosin and plaster of Paris. Dr. Fleming, in his *Account of the Salt Range*, says the Natives use plaster of Paris, mixed with pure lime, to produce their finest

qualities of shining marble-like *chúnám*. It is also largely employed as a whitewash.

For the materials employed along with lime in the formation of special cements, the reader is referred above (pp. 292-3) and to the respective positions in this work of the articles there indicated. Special Cements.

Marble.—The best-known marbles are those of the Aravalli series, which include the quarries of Jodhpur (Makrána), of Tonkra in Kishengarh, of Kharwar in Ajmir, as well as of Raialo in Jaipur, all in Rajputana, and of Jabbalpur in the Central Provinces. Within a radius of eight miles around Makrana there are something like 100 quarries, but of these only 15 are at present worked. They vary in depth from 30 to 75 feet, and follow the vein. The marble is excavated by blasting, and is then cut into the required size by steel saws. It is hauled to the surface on wooden rollers, and by manual labour. The quality of the stone is generally better according to the depth it is worked, but owing to the crude appliances used for hoisting to the surface, deep mines are impossible. The dust and fragments produced during mining operations at Makrana are burnt into lime, and this quality is much appreciated for the finer kinds of plastering. Marble.
Rajputana.
O. Prov. [Cf. *Journ. Queen Vict. Ind. Mem. Fund*, March 1904, 19-25.] Lime.

Colours.—The white marbles of Raialo are highly valued for filagree screens (*jálú*), of which numerous fine examples exist at Abu, Agra, Ahmedabad, Delhi, etc. The yellow marble of Jaisalmir (*khattu*) is a pure yellow, not white and yellow veined. It is used in the tomb of Ghayas Beg and his wife at Agra, and is so abundant as to be locally worked up as an ordinary building stone. The black marble found at Bainslana is carved into statues and toys. The black material in the inlaid work of the Taj and other Mughal buildings is a calcareous shale found in the lower Vindhyan series at Chitor. The handsome, mottled, green marble of Motipura in Baroda State, as also the grey and pink marbles of Narwár in Kishengarh State, are much admired and largely used for ornamental purposes. The onyx-marble of Nurpur and Shahpur, Panjáb, is famous. This is a cream-coloured rock streaked cloud-like with purple, hence its name *badal* (cloud). An exquisitely beautiful variety of onyx-marble is found near Jhuli in Baluchistan, too remote from civilisation to admit of its utilisation. The marbles and limes of Narnaul in Patiala State are also well known. White
Marbles.
Yellow Marble.
Black.
Mottled.
Grey and Pink.
Onyx-marble. [Cf. *Rec. Geol. Surv. Ind.*, 1906, xxxiii., 59-60.] It is commonly believed that the reason why the marble used in the Taj and other buildings has remained for three hundred years without getting tarnished is due to its coarseness of grain and chemical purity. A coarsely crystalline dolomite marble occurs near Mirganj, 11 miles west of Jabbalpur, but it includes numerous crystals of tremolite, and its use for tombstones at Jabbalpur shows that it is of inferior quality as a marble stone when exposed to the weather. In Burma the beautiful semi-transparent white marble so extensively employed for the figures of Gautama is obtained chiefly from the Tsygen hills in the Madeya Sub-division of the Mandalay district and near Sagaing. Coarse Grain.
Burma.

Uses.—Marble is thus in extensive demand for the decoration of sumptuous dwelling-houses, palaces, temples and mosques, and in the construction of idols, ornaments, toys, etc. A highly instructive account of its uses in the buildings of Agra will be found in the (*Agra Gazetteer* 1884, vii., 684-716, 728-35). In the *Ain-i-Akbari* mention is made Uses of Marble.

Inlaying.

of the skill of the Indian stone-carvers, but not of the art of stone inlaying. Both arts were, however, greatly improved during the time of Akbar's son and grandson. The use of marble became, in fact, the dominant feature of the new school of architecture that assumed such stupendous proportions with the Mughal rulers of India. Perhaps one of the most pleasing and at the same time surprising features of that great school of Indian architecture might be said to be the marvellous fligree screens (*jali* work), in sandstone or marble, that take the place of the glass windows of European buildings. Keene (*Stone Indust. of Agra*) gives a very accurate and impressive account of the screens at Fatehpur Sikri (constructed 1581 A.D.). "The outer screens," he says, "are so minutely pierced that they actually look like lace at a distance, and illuminate the mortuary chamber with a solemn half-light which resembles nothing else that I have seen." In Agra a fairly extensive industry exists in the preparation of screens, tables, fancy boxes, picture frames, plates, vases, etc., as also models of the Taj and other ancient monuments. These are mostly done in white marble, inlaid with agate, carbuncle, carnelian, chalcedony, jade, jasper, lapis-lazuli, topaz, turquoise, bloodstones, garnets, rubies, sapphires, etc. This art is supposed to have sprung into perfection with the tomb of Itmad-u-Daula and the Taj (A.D. 1627-1658), and to have almost immediately thereafter gradually declined until at the beginning of the 19th century it had practically disappeared. It is said to have been revived by Dr. J. Murray about fifty years later. It has flourished ever since, the goods produced in Agra being carried for sale by the traders in Indian art wares all over India.

Gypsum

LIME SULPHATE: GYPSUM, Plaster of Paris.—This is the hydrous calcium sulphate generally known as GYPSUM; when in a fine grained condition, ALABASTER; and when in transparent crystals, SELENITE. On being calcined it parts with some of its water and then constitutes PLASTER OF PARIS. The powder thus produced on the addition of water gradually sets, and as it does so expands slightly. It is this property that has made plaster of Paris so exceedingly valuable for making casts and moulds. In India sulphate of lime is known by an extensive series of names such as *kuinar*, *kurpura-silasit*, *karsi*, *sang-i-jerdhat*, *surma safed*, *makol*, *jirah*, etc. Plaster of Paris is generally known as *gach*.

Occur-
rence.
Madras.

Bombay.

Kach.
Sind.
Baluchistan.

Occurrence.—In the Madras Presidency it has been met with abundantly, but in an impure form, in the cretaceous rocks of Trichinopoly. Masses of gypsum and crystals of selenite are occasionally found in the clays of Chingleput. In Nellore, crystals of greater purity than those found near Madras have been recorded as fairly prevalent. In Bombay, selenite occurs in the marine deposits near the city, also in Kathiawar and in some parts of the Deccan. Very excellent gypsum is found in Kach. In Sind, deposits frequently 3 to 4 feet thick occur near the top of the Gaj beds of the Kirthar range. The Mud Gorge, on the Harnai route to Quetta, owes its intractable character to the circumstance that much sulphate of lime is there present, and very largely in the anhydrite

condition. This absorbs water and thereby expands 33 per cent. The adjacent materials are in consequence continuously displaced, and the Mud Gorge may, therefore, be said to be in a state of constant change.

In Rajputana, at Nagor in Jodhpur, a bed of gypsum probably not less than 5 feet thick has been worked to some extent. A similar occurrence is worked at Jamsar in Bikanir State. While excavating a well at Falod, gypsum of a very pure kind was found, but at too great a depth to be of much value. In the Panjáb (Bannu district) the mineral occurs in Kalabagh and in Khasor, but is not utilised. The Kohat district contains gypsum in great abundance. Ball says "it might be obtained by open quarrying in any quantity, but is not worked." The Salt Range possesses gypsum in enormous quantity, associated with rock salt. The Spiti Valley has gypsum of a snowy whiteness. In the United Provinces deposits of gypsum have been reported as met with in Dehra Dun, Kumaon, and Garhwal. Middlemiss (*Rec. Geol. Surv. Ind.*, 1889, xxii., pt. 2) gives a full account of the gypsum of Nehal Nuddi in Kumaon. [*Cf.* Hayden, *Mem. Geol. Surv. Ind.*, xxxvi., pt. 1, pl. 16.] *The Pioneer* (July 27, 1888) announced that gypsum had been found at a locality some 19 miles distant from Haldwani, a station on the Rohilkhand and Kumaon Railway. In Burma gypsum has been found, but not in sufficient quantity to be of much commercial importance.

Rajputana.

Panjáb.

U. Prov.

Burma.

Industrial and Agricultural Uses.—For a great many years gypsum has been regarded as a manure of exceptional merit, especially for leguminous crops and for certain soils. It has recently been found to vastly increase the yield of indigo, so that a large demand seems likely to arise for it. The reader should consult the observations already made (p. 53) regarding the use of this salt as a neutralising agent, or rather one which so modifies the physical conditions of the soil as to bring it into a culturable state. Of manures that contain gypsum mention may be made of "superphosphate," which is a mixture of calcium sulphate with an acid phosphate of lime—the essential manurial constituent. It is prepared by the treatment of phosphatic minerals with sulphuric acid (Mukerji, *Handbook Ind. Agri.*, 1901, 569–71).

Industrial
Uses.
Manure.

The next most important use for gypsum is the numerous methods of utilising plaster of Paris. In 1852 Dr. Buist drew attention to the interesting fact that the Natives of Sind had, from ancient times, been in the habit of casting lattices and openwork screens to be used within houses to allow of free circulation of air. The Marwaris very cleverly make what might be called stained-glass windows by taking two lattice screens, made of plaster of Paris, of identical pattern, and placing between these fragments of coloured glass so arranged as to bring out the desired colour in design. The screens are then firmly fastened together and the pieces of glass secured in their positions by a thin layer of liquid plaster being run over the lattice upon which the glasses have been arranged before pressing home (on the top) the second layer of lattice. In many parts of Rajputana and of the Panjáb the walls and ceilings of palaces are richly ornamented, in arabesque design, with glass. These are silvered behind or backed with plated metal discs or with coloured tinfoil, or they are painted on the surface and embedded singly or collectively in wooden frames, within a plaster, which consists mainly, if not entirely, of plaster of Paris. This work might be described

Sind Lattices.

Rajputana
Stained
Windows.

Shish-mosaics.

as a kind of mosaic, and from the fact of pieces of glass (*shishah*) being used, has come to be spoken of as *shish-mosaic*. The famous *Shish-mahal* (the Palace of Glass) at Agra, the *Shish-mahal* at Lahore, and the *Shish-mahal* in the ruined city of Amber (near Jaipur) are perhaps the best examples of this class of work. Mr. L. Kipling very truly says, "The effect of the *shish* or mirror mosaic, though brilliant, narrowly escapes the charge of vulgarity," so that it is not much to be regretted that the art may be said to be hardly practised at the present day. [*Cf.* Plaster of Paris work in *Ind. Art at Delhi*, 1903, 95-6.]

Casting and
Moulding.

While it would thus seem that certain uses of plaster of Paris have been well known to the Natives of India for a considerable period at all events, a knowledge in the art of casting figures, ornaments and toys in that material is of comparatively recent date, and originated with the modern Schools of Art. While that is so, it is surprising to learn from Stein (*Ancient Khotan*, 244, etc.) that the whole of the stucco work discovered by him consisted very largely of plaster of Paris. Moreover, he tells us that the figures, idols, etc., had in many instances been moulded and elaborations accomplished in the form of extra figures, etc., by a process of *appliqué*. Grooves had been made on the plaster background to allow of the attachment of these extra mouldings, which were finally fused into their positions by liquid plaster. Since plaster of Paris moulding is quite modern in India proper, the ancient people of Khotan must have either discovered that art spontaneously or learned of it through their dealings with other than Indian-races (see p. 713). So late as 1885, while engaged supervising the preparation of life-sized statues or models of ethnological subjects that were required for the Colonial and Indian Exhibition, I experienced the greatest possible difficulty in inducing the Krishnagar modellers to substitute plaster of Paris for clay. I procured a supply of gypsum from the Salt Range, had it fired in Calcutta, and found that it yielded a most excellent modelling plaster, and at a cheaper rate than I could purchase the imported article, which alone had been previously procurable in Calcutta. But my clay-modellers struck work, and I had to import others from Lucknow, and thus successfully threaten them with dismissal, before I could induce the Krishnagar men to resume operations. I mention this circumstance as showing the quality of the Indian plaster of Paris and its recent use in castings.

Ancient Khotan.

Krishnagar
Modellers.

Alabaster.

Alabaster, where met with, is largely utilised in the manufacture of ornaments and toys. The dark-green form procured from Garhwal is regularly made into elegant cups and saucers and even large bowls that are much admired by the richer Native gentlemen of Northern India. The same material, drawn from various sources, is to some extent utilised by the stone-carvers in Agra and other centres of that industry. [*Cf.* Blount and Bloxam, *Chem. for Engin. and Manuf.*, 1900, 131-2.]

Trade.

Marble.

TRADE IN LIME, MARBLE, ETC.—With a country that possesses so many rich deposits of lime and marble, it is surprising to read of the large foreign imports that regularly take place. In the Calcutta press may be seen, almost daily, advertisements of dealers prepared to supply the "Best Italian Carrara Marbles" and "Best Belgian Jet Black Marbles" (*Journ. Soc. Arts*, 1901). So again, it is not uncommon to find mention of the coloured marbles of Montarrenti, Montalcino and Caldana, which

are unrivalled in Italy for the beauty of their tints. It is well to remember that many of the columns, altars and floors of the Tuscan cathedrals, which are the admiration of the world, were constructed of these marbles. Mention is also frequently made in the Indian press of the Greek marbles, especially those of the Pentilikon quarries near Athens, and from the famous quarries in Thessaly, from which the genuine "Verde Antico" marbles were obtained. Many of the marbles met with in Indian household ornamentation have been derived from European quarries.

The official returns of foreign trade adopt two headings, under which lime, marble, etc., are included. These are "Stone and Marble," and "Building Materials," such as "Cement" and "Chalk" and "Lime." The IMPORTS of Stone and Marble have ranged from 204,205 to 362,554 cwt. during the five years 1902-7, or a valuation of from 2½ to 4½ lakhs of rupees. The chief item in point of bulk is stone from Arabia and Mauritius, used for road-making in Calcutta; and in point of value, marble from Italy to the extent of an average of 2½ lakhs of rupees for each of the years named. Turning now to the Chalk and Lime. The quantity imported is annually about 30,000 to 50,000 cwt., valued at about Rs. 30,000 to 36,000, and comes almost exclusively from the United Kingdom and is received mainly by Bengal. The EXPORTS from India have never exceeded 53,000 cwt., or a valuation of just under one lakh of rupees. These consignments go mostly from Madras to Ceylon. Of the Cements a very different story has to be told. The totals (during 1902-7) have ranged from 646,356 cwt. in 1902-3 to 1,788,428 in 1905-6, valued at from 13½ to 32 lakhs of rupees. In 1906-7 the imports were 1,714,506 cwt., valued at Rs. 30,87,484. Fully three-quarters of the supply comes from the United Kingdom, and the balance mainly from Belgium, France and Germany. Bengal takes very nearly half the imports: the remainder goes to Bombay, Burma, Madras and Sind in the order named. Of the internal traffic in Stone and Lime very little can be learned. The rail and riverborne returns of minerals show a steady progression from an import of 6,733,264 cwt. in 1902-3 to 12,744,352 cwt. in 1905-6, with 12,149,239 cwt. in 1906-7. Taking the last year the chief receiving centres for Marble and Stone were:—Madras Ports, 3,443,282 cwt. (chiefly from Madras Presidency); Calcutta, 2,040,834 cwt. (from Bengal); and the United Provinces, 569,874 cwt. (from Rajputana and Central India). Chalk and Lime:—Calcutta, 1,606,523 cwt. (from Assam, Eastern Bengal, Rajputana and Central India, Central Provinces and Calcutta); and the United Provinces, 244,421 cwt. (from the Central Provinces and Nizam's Territory). Lastly, Others—a total of 66,986 cwt. Thus Assam and Madras are the chief sources of the lime traded in over India, but Bombay and Burma seem to be entirely self-supporting, as there are practically no records of interchanges from or to these provinces.

The above, out of the library of books that might be cited as dealing more or less fully with the subject of *Linum* (Linseed and Flax), may be consulted by the reader desirous of botanical, historical and industrial details. The names given to these products in Europe and Asia are so extensive and varied that only those of most frequent use can be here mentioned:—linseed, *linum*, *lein*, *lin*, *lino*, *linu*; flax, *vlas*, *flachs*, etc.; *alsi*, *alshi*, *alish*, *tisi*, *chikna*, *pesu*, *bijri*, *keun*, *zighir*, *javasa*, *atasi*, *alashi*, *asina*, *mushina*, *auma*, *ksumá*, *umá ziggar*, *kattan*, *zaghu*, *pischta*, etc., etc.

Perennial
Flax.

pecies and aces.—The Linseed and Flax Plant is cultivated throughout the plains of India, and up to altitudes of 6,000 feet above the sea. According to De Candolle (followed by most other botanical writers), it is indigenous to certain localities situate between the Persian Gulf and the Caspian and Black Seas. A consensus of opinion also favours belief that originally the perennial flax (*Linum angustifolium*) was the plant that in Europe was first cultivated for its fibre—a plant that is wild south of the Alps; and further that its displacement from popular favour took place about the close of the Stone Age of European history.

Plant first
cultivated for
Fibre.

There is no evidence of *L. angustifolium* ever having been met with in India either wild or cultivated. It would seem highly likely (as recently pointed out to me by Mr. J. R. Drummond) that the economic information recorded in the *Dictionary* under *L. strictum* may be incorrect—the plant intended to be denoted as cultivated in Afghanistan having very possibly been one of the numerous races of the ordinary linseed. That being so, the only truly wild *Linum* within the Indian area, at all related to the oil-yielding *L. usitatissimum*, is *L. perenne*, Linn.—a species found in Western Tibet at altitudes of 9,000 to 13,000 feet. This is reputed to have been occasionally seen under a crude cultivation, the seeds being valued on account of the oil they contain.

Indian
Wild Plant.

Thus we are left completely in the dark, not only as to when and where the substitution of *L. usitatissimum* for *L. angustifolium* took place in Europe, but as to the origin of the stock that now affords the linseed of Indian commerce. According to some writers *L. usitatissimum*, the modern flax-yielding plant of Europe, was derived from India.

Origin of
Indian Stock.

istory.—While the classic records of India certainly do make mention of *atási*, *umá*, *ksumá*, etc., etc., no account, either of the oil-seed or of the fibre, is such as to remove all possible doubt that linseed and flax were undoubtedly indicated, but it can be said that greater certainty prevails regarding the oil than the fibre. In the *Institutes of Manu* (bk. ii., 41) we read that the garments of students should consist of skins above and of fabrics of hemp, flax (*ksumá*) or wool below. So again (bk. v., 121), a man who knows the law is likened to purified linen cloth (*ksumá*). Lastly a Brahmin, if he be compelled to make his living as a trader (bk. x., 87), must not sell dyed cloth or garments of hemp, flax (*ksumá*) and wool. Thus there would seem no doubt that the word *ksumá* is of frequent occurrence, and that it denoted a fibre which was purified (bleached, doubtless). Kálidása speaks of the white colour of the cloth. But whether *ksumá* originally denoted linen or silk, or *rhea*, or *Calotropis*, or some such fibre, but not necessarily linen, seems a doubtful question. Most commentators have, however, accepted the name *ksumá* as linen, and often with an atmosphere of such assurance as to convey the impression that there was no doubt, and could be no doubt, as to its determination. But if that view be correct it is, to say the least of it, curious that to-day the only use of the plant, known to the people of India, is as a source of linseed and linseed oil, not of fibre (*ksumá*) or garments of the same. In fact, it is the all but universal belief that the linseed plant will not yield fibre of sufficient merit to repay the expense of its separation and purification. Are we to suppose, then, that since classic times a complete revolution has in India taken place, and that cultivation as a source of oil-seed is comparatively modern—a consequence possibly of the Muhammadan conquests of India, if not of European commerce? Or is the other explanation more acceptable, namely that the passages above indicated refer to an entirely different plant (possibly cotton) or denote experience obtained and opinions held prior to the invasion of India, and, therefore, prior to any knowledge of the plant as a source of oil? Mr. F. W. Thomas (Librarian to the India Office) draws my attention to the fact that in *Susruta* (800 B.C.) *atási* oil is spoken of as having a slight smell of flesh; of its being used like that of hemp and sesamum for poultices; and of its being pungent, light, penetrating and laxative. These are characters that would seem to denote linseed, so that the *atási* of Sanskrit authors stands a better chance of having been linseed than the *umá* or *ksumá* of being flax. Dutt (*Mat. Med. Hind.*, 1900, 292) simply gives, in an appendix to his work, the name *atási* as the Sanskrit of *Linum*; *masina*, its Bengali; and *tisi*, its Hindustani; so that it may be inferred to have been a drug, in the opinion of the Sanskrit authors, that was unworthy of special consideration.

Restrictions
against the
Fibre.

Linseed Oil.

Atási versus
Ksumá.

The oil is occasionally mentioned, however, in the *Ain-i-Akbari* and in a few other such publications, but on the other hand all the early European travellers in India whose evidence is generally regarded as of value historically, are singularly silent regarding both linseed and flax. Rheede, Rumphius and Burmann make no mention of any species of *Linum*. The East India Company's Records, as published by Birdwood and Foster (*First Letter Book*, 1600 to 1619), the subsequent six volumes of *Letters Received by The East India Company*, as also the still more recent work, *The English Factories in India*, 1618-21, prepared by Foster, do not contain any references to linseed or flax. Milburn (*Or. Comm.*, 1813), who deals with all the articles traded in between England and the East Indies, China and Japan of that date, makes not the slightest allusion to linseed or flax, though he deals with sesamum castor and other oils and oil-seeds as exported from India. Next to nothing of a historic character can, therefore, be recorded of the early production and trade in linseed. The only point at all conclusive is that the Muhammadans seem more closely connected with the origin of the traffic than the Hindus.

Linseed
Oil.

Not mentioned
by E.I.C.

Buchanan-Hamilton (*Stat. Acc. Dinaj.* (written subsequent to 1807), 174) enumerates "Flax or Linseed, *mosina*" among his agricultural crops of Bengal, but makes no observations regarding it. Neither in his *Journey through Mysore*, etc., 1807, nor in his *Account of the Kingdom of Nepal* (1819) does he refer to either flax or linseed. Ainslie (1826) says there was then a good deal of flax being cultivated in Upper India, especially in Bengal, for making oil; he then adds,—"of late years it has also become an object in the lower provinces." Carey (*As. Res.*, 1808, x., 15) was apparently one of the first authors who wrote definitely regarding Indian linseed. He says that the oil is mixed with mustard to such an extent that it is "unfit" for painting or the other useful purposes

Buchanan-
Hamilton's

Carey's
Account.

to which it is applied in Europe. Of flax he says the Natives know nothing of its use to make thread. In 1825 Thornton brought out the second edition of Milburn's *Oriental Commerce*, in which work it is stated that "flax is very generally cultivated in Bengal and Bihar for the oil which is obtained from the seeds, the stalks being rejected as useless." [Cf. Rawlinson, *Hist. Ancient Egypt*, 1881, i., 62-3.]

Thus then from the observations already made, it may be inferred that the study of the production and utilisation of *L. usitatissimum* resolves itself into two sections, Flax and Linseed. These cannot of course be exhaustively dealt with, but I shall dispose of Flax (to India infinitely the lesser important product) first of all, and in a very few words.

storic
periments.

FLAX AND LINEN.—The possibility of combining the production of linseed with the supply of flax has been spasmodically raised in India every now and again during the past hundred years or so. An important series of experiments and investigations were in consequence conducted in 1790 to 1810; another in 1840; and still a third in 1872, the object being not so much to ascertain whether a profitable combined seed and fibre industry could be organised, as to ascertain whether flax could become a commercial product of India at all. In the *Proceedings of the Honourable the East India Company*, preserved in the records of the Board of Revenue, Bengal, of date 1805-7, are many interesting details of the early experiments. Six Arab flax-dressers were sent from Bassora to Bengal, but failed to produce good fibre from the plants raised from the seed specially imported from Bassora. Roxburgh, in 1801, and again in 1806, gave accounts of the experiments he had conducted at the Company's Hemp Farm near Calcutta. An army of writers, down to Royle's time, may be said to have recorded their theories or narrated their experiments. On each occasion of special investigation, the results obtained were not deemed encouraging. But more recently still a new phase has arisen that may in the future assume some importance. The demand for cheap cordage, to be used as "binders," has suggested the possibility that the stems of the linseed-yielding plants (while they doubtless do not contain fibre of sufficient merit and abundance to justify being elaborately separated, cleaned, and placed on the market as Indian flax) may still by a simple method of preparation afford a cordage fibre that, as a catch crop, might undersell even jute. At present the stems of the linseed plant are not used in any way, and if they could be turned into a profitable by-product a great boon would doubtless be conferred on the Indian cultivators.

Vesque (*Traité de Bot. Agri. et Indust.*, 1885, 495) very properly observes that climate exercises a considerable influence on the qualities of fibre or seed produced. In warm countries the fibre is least abundant, but the seed crop profuse. He then adds that the seeds obtained from a fibre crop may be useful for oil, but they are imperfectly formed and can never be used for reproduction. Conversely, if the seeds be fully developed, the fibre is all but ruined. If the combination crop of flax and linseed be in India seriously contemplated in the future, the plants would have to be sickled close to the ground or pulled up by the root, the seeds being thrashed out and the stems subsequently treated for their fibre. But the question of all others that naturally arises is this—can the same plant yield both products profitably? Would it not be preferable to grow separate crops?

Extensive experiments would very possibly have to be conducted by the various Governments of India in order to ascertain the conditions

necessary for a combination crop. It would have to be discovered whether a stock could be evolved a little richer in fibre than that presently grown, but which would still yield a fair crop of seed. The class of soils suited, the seasons of sowing, the methods of cultivation, and the period at which the harvest should be made, etc., etc., are some of the issues of importance that the Indian cultivators could not be trusted to investigate and solve for themselves. Then the methods and appliances required for separation of the fibre would have to be demonstrated, and above all, the final conclusion made abundantly clear, namely that the proposed departures from the time-honoured usages, in linseed cultivation, were in the *raiyats'* best interests, and that the vastly increased cost of seed to acre, the new expenditure in fibre-extracting appliances and the extra labour involved, could all be justified by the much greater returns obtained.

Features to be Tested.

In testing these and many other such aspects of the proposed new departure, the experience gained in the past (very nearly futile) experiments would have to be carefully borne in mind and the shortcomings guarded against. These results will be found in the *Dictionary* (v., 10-35) and it will be seen that the idea of utilising the fibre of the linseed plant is by no means new, but that several persons have unsuccessfully tried to obtain a useful fibre from it. For example, we read that some years ago the late Mr. Savi of Mohesgunge in Eastern Bengal found the stems of linseed too thin and woody to afford fibre. In Assam the Director of Agriculture, we are told, made some experiments in 1901 to ascertain if flax could be produced in that province. The plants grew well enough but were laid by heavy rain, and when taken up the fibre was found to be rotten. The following year better results were obtained, but the want of proper machinery, to separate the fibre, resulted in a report that denoted imperfect work rather than defective crop. In the report for 1904 it is stated that as the sowings had been made in spring, the crop had to ripen in July during the middle of the rains. It was accordingly contemplated to try an autumn sowing, notwithstanding the risk of frost. The report adds, "By sowing the crop in autumn it may grow and ripen in dry weather and escape the baneful influence of the monsoon rains."

Unsuccessful Experiments.

Baneful Influence.

Bihar.

Recent Experiments.—It may now be stated that the Bihar Planters' Association have recently taken interest in the possibility of flax-growing being usefully resorted to by the indigo planters as a supplementary crop. At a meeting of the Dundee Chamber of Commerce (Sept. 20, 1904) this subject was alluded to with much interest, and a reference made to a committee having obtained an audience of His Majesty's Secretary of State, with the express object of urging this matter as specially worthy of the attention of the Government of India. The samples procured from Bihar were pronounced such as to suit a large portion of the trade. It would thus seem that within the past few years the question of flax-production alone, as well as of flax and linseed combined, have been once more engaging the attention of many persons, and it may be said that it will be a fortunate circumstance if a solution of the problem be at last found and a new and prosperous industry given to India, in continuation of the already long list of those that owe their existence or development to British commercial enterprise. It must never be forgotten, however, that linseed is at best a risky crop, and one that is resorted to by the

Dundee Chamber of Commerce.

More Hopeful.

Risky Crop.

raiyat for rent-paying purposes, but only when necessity occurs and favourable conditions are likely to prevail.

Recent Results.

Since the above was penned there has come to hand a report of the experiments recently conducted in Bihar, written by Bernard Coventry (*Agri. Journ. Ind.*, i., pt. iii., 192-200). It would appear that a few indigo concerns have experimented with flax during the past four years, and Coventry's remarks are apparently the result of experience gained. The following extract may be accepted as conveying the chief facts:—

Average Yield.

"There is as much fibre in the plant grown in India as at home, namely, about 20 per cent. of dried straw. The average yield of retted and dried straw at Dooriah from sowing at the rate of 2 maunds of seed, was 40 maunds per acre, and the percentage of fibre obtained from the straw was 15 per cent., or 6 maunds of fibre per acre. This should have given $4\frac{1}{2}$ maunds of good fibre and $1\frac{1}{2}$ maunds of tow, that is to say, the proportion of good fibre to tow should have been as three to one, but in point of fact it was only half good fibre and half tow."

Good Fibre.

"The flax from the first year's experiments fetched £30 a ton, the second year £35, and this year it is expected to fetch £40 a ton, owing to its better quality. The price of tow was about £10 a ton. The cost of production, including cultivation, seed, manufacture, shipping, insurance, and other outlay expenditure, amounts to Rs. 62 per acre. Taking the 6 maunds of fibre to have sold at £25 a ton including tow, equal to say Rs. 13 per maund, we have a gross return of Rs. 78 per acre and a profit of Rs. 16."

Prices
Realised.

Profit.

Coventry contends accordingly that the cultivation of the plant has been accomplished successfully, but concludes his report almost in the words used by Dr. Jameson in 1859, viz., "All that is required to market a useful crop in India are some good instructors to show how the fibre is to be prepared and fitted for the market, and good seed and machinery." Lastly, Coventry, like most other writers on this subject, adds, "There are two separate but closely connected problems for investigation: *first*, the possibility of establishing a new industry for the growth of flax as a fibre crop for the production of high-grade fibre alone; *second*, the possibility of introducing a system whereby fibre, probably of a lower quality, could be produced in combination with the existing large cultivation of linseed for oil-seeds." Students of this subject will find the information furnished by Hanausek (*Micro. Tech. Prod.* (Winton and Barber, transl.), 1907, 73-7) highly instructive. They should also consult the recent results by Finlow (*Dept. E. Beng. and Assam*, 1906-7, app. ii.).

Two
Proble

Paper
aterial.

Exhausting
Crop.

It has been often urged that, even if the separation of a fibre should prove unremunerative, the stems might become of great value to the paper-maker. But the crop is well known to be an exhausting one, and on that account is often barred by many leases, hence an effort should be made to overcome these objections by improvements in manuring. Fowls are known to fatten very rapidly if allowed to stray over linseed fields, and a certain percentage of linseed-cake is the world over recognised as one of the very best food materials for prolonging and improving the milk of cows, especially when butter manufacture is an important consideration. It has, in fact, been remarked that along the foot of the lower North-West Himalaya, linseed is at times sown mainly as a cattle food for milch buffaloes—the oil being only a secondary consideration. In this connection, however, attention may be drawn to a brief note by Leather

Food Value.

Fodder.

(*Cyanogenesis in Plants*, in *Agri. Journ. Ind.*, i., pt. iii., 225) on a poisonous property at times possessed by the linseed plant. He mentions a case where cattle ate some immature linseed as fodder with the result that fifty-two died in a few hours. A specimen of the plant sent for examination contained a cyanogenetic glucoside, and yielded prussic acid when crushed in water.

Poisonous
Property.

LINSEED AND LINSEED OIL.—The seed obtained from the cultivated *L. usitatissimum* is known as LINSEED, the oil expressed therefrom is LINSEED-OIL, and the cake LINSEED-CAKE.

The object being to promote flowering, not to produce long, straight, fibre-yielding stems, the seed is sown much thinner than is generally the case with European flax. The result of this special cultivation has been to develop several well-marked RACES, all of which possess one characteristic—a much-branched stem. There are two readily recognised kinds, namely a white-seeded and a red-seeded, and of each of these at least two grades with either “bold” or “small” forms of the seed. The latter may be only a condition of defective cultivation or immaturity of crop, but commercially the bold seed is the form of greatest value. The subject of the cultivated races of linseed is, however, too imperfectly understood to allow of more being at present said regarding them than that many distinct forms exist. It would, therefore, be the most obvious course to pursue, in any attempt at new developments of the linseed traffic, to improve the stock by careful selection in the direction desired, rather than to attempt the acclimatisation of exotic stocks. It is well known that the quality and yield of oil varies greatly in the seed of one country as compared with that of another. The white-seeded form has usually white coloured flowers, the brown-seeded blue flowers. Moreover, the white seed has a thinner shell, and contains nearly 2 per cent. more oil than is the case with the red. These facts have led to many inquiries as to the white-seeded plant being grown separately and the seed sent into the market pure. The demand for such pure seed has never, however, been so large and constant, nor the hopes of increased price sufficiently encouraging, to tempt producers to give the attention to the subject that would be necessary. Moreover, it is said that the quality indicated is not constant. In other words, under altered conditions, the white-seeded plant may produce red seed and thus frustrate the production of a pure crop. [Cf. Leather, *Effect of Change of Climate on Amount of Oil in Linseed*, in *Agri. Journ. Ind.*, 1906, i., pt. iv., 413–4.]

Area under Linseed.—Very often linseed is grown as a mixed crop, being sown along with other oil-seeds and the two reaped together and used in the production of well-known blends of oils. At other times linseed constitutes lines through or borders to other crops, so that the greatest difficulty often prevails in determining the actual area under the crop. This is more especially the case in the United Provinces. But when grown mixed, the crop is all but universally intended for home markets, the crop grown for export being usually pure.

Area.

Mixed
Cultivation.

To the Natives of India a drying oil is of no consequence since they do not require an oil with that property, hence the frequent admixture with mustard-oil seed, which greatly reduces the value of the produce from the standpoint of a drying oil. But such admixture is more often than not accidental, through produce being purchased that was not intended for the foreign market. Voelcker (*Improv. Ind. Agri.*, 1893, 285) discusses

the adulteration or admixture of linseed and says that it is usually purchased in Bombay on a basis of 94 per cent. purity, and elsewhere on a basis of 96. It is, therefore, hardly to the interest of the shipper to get absolutely pure seed, since nothing more is paid for it in Europe than that adulterated to the extent named. Voelcker adds that an attempt was made some years ago to buy upon the basis of "absolute purity," but this proved a dead letter, since there was no demand in the home market for pure linseed.

During the past fifteen years the crop has fluctuated very greatly. Thus in 1891-2 it was 3,211,000 acres pure and 545,000 acres mixed; in 1895-6 it was 2,954,093 pure and 560,000 mixed; in 1899-1900, 1,648,903 pure and 409,000 mixed; in 1903-4, 3,609,079 pure and 592,000 mixed; in 1904-5, 3,747,400 pure and 647,000 mixed; in 1905-6, 2,700,400 pure and 567,000 mixed, while the *Final Memorandum* issued by the Commercial Intelligence Department estimates the area for 1906-7 as 3,028,200 pure and 633,000 mixed. Analysing the returns for the year 1905-6, by way of illustration of the distribution of production, we learn that Assam had 55,709; Eastern Bengal 103,000; Bengal 726,500; Agra 185,034; Oudh 60,880; Bombay 139,623; Central Provinces 812,068; Berar 96,703 acres, the balance on the total area being in Madras, Panjáb, Rajputana and Central India, and lastly Burma. The highest of all the unimportant areas is usually Madras, which in 1905-6 had 21,099 acres; and Sind the lowest, with 3 acres under the crop.

PRODUCTION.—It may now be useful to devote a few pages to a series of notes on the linseed of the chief areas of Indian production:—

1. **BENGAL (including Eastern Bengal).**—As already indicated, Bengal, of all the provinces of India, has usually the largest extent of land under this crop, though in the year specially dealt with it had less than the Central Provinces. The districts of Bengal that had in 1905-6 the greatest acreage of linseed were Darbhanga, 138,500; Gaya, 80,000; Nadia, 49,000; Saran, 72,000; Champarun, 66,300; Muzaffarpur, 41,200; Jessore, 29,900; Murshidabad, 29,100; Bardwan, 22,500; Noakhali, 22,000; and Backerganj, 20,000 acres. It is thus a crop that may be spoken of as produced most abundantly within the indigo districts. At all events it is mainly grown, so far as Bengal is concerned, in Tirhut and Bihar. Mukerji (*Handbook Ind Agri.*, 272-4) says it is believed to love well-drained heavy, loamy soils, especially if rich in lime, such as those often under mustard or *til* crops. It requires more or less the same soil, in fact, as wheat and gram. The land should be prepared in September, and thorough deep ploughing is desirable. Before the close of the monsoons the sowings are usually completed. The seed rate has been given as 8 to 12 lb. to the acre. If sown late, irrigation may be necessary, but when the plant is in flower rainfall is injurious. The crop is harvested by the end of February or the beginning of March and the seed extracted by fanning. Six to eight maunds of seed (say 500 to 700 lb.) is the average produce per acre. The straw is useless as fodder, and indeed it is even said that green plants eaten by cattle have been known to prove fatal. The seed is held to yield one-fourth of its weight of oil. The cake is regarded more valuable as food for milch cows than either *rai* or *tori* cakes, though the butter is said to be softer than that obtained where mustard- or cotton-seed cake has been given to the cows. Basu speaks of the straw of linseed being reduced to *bhusa* and given to cattle in mixtures with the *bhusa* of wheat, barley, gram, lentils, etc. It is considered as heating, and therefore seldom given to animals by itself. The crop is sometimes barren and thus becomes a dead loss to the cultivators.

Trade in Bengal (see p. 728).—In the *Annual Report on the Maritime Trade of Bengal* (1904-5, 24) it is stated that "the quantity shipped rose by 26·7 per cent. and was the highest on record, the year 1898-9 coming next, but the value advanced by 6·6 per cent. only. In May, 1903, the price of linseed in Calcutta was Rs. 5-0-6 per maund; while in May, 1904, it was Rs. 3-10. The world's production in the year 1904 was enormous and in April the home price fell to 29s. per quarter, a figure not approached since July, 1896, when the price was 28s. 6d.

The average price for 1904 was 33s. as compared with 39s. in 1903. There was an extremely large crop in Argentina, and the United Kingdom imported even more from that country than from British India. The United Kingdom took 55·5 per cent. of the quantity shipped from Calcutta, and Germany 33·7 per cent. Exports to the United States, which did not exist in the previous year, totalled 60,047 cwt." "In the United Provinces the outturn of pure linseed during the year was 26·3 per cent. better than the season before, and in Bengal the improvement was 5·7 per cent., or 41·4 per cent. above the ten years' average." [Cf. Basu, *Agri. Lohardaga*, 1890, pt. ii., 35; Banerjee, *Agri. Cuttack*, 1893, 89.]

Shares of
Exports.

2. **CENTRAL PROVINCES AND BERAR.**—Judged of by the area devoted to the crop, these provinces are undoubtedly the second most important centres of production, and are usually just under the Bengal area. In 1905–6 the Central Provinces had 812,068 acres devoted to linseed and Berar had 96,703, or close on a million acres between them. A slight increase of these areas would have to be made to cover the mixed cultivations of linseed and wheat or linseed and gram, etc., which expressed as pure linseed usually represents a cultivation of say 30,000 acres. The districts enumerated in sequence of linseed acreage were in the *Central Provinces*:—Raipur, 181,699; Bilaspur, 109,993; Nagpur, 66,980; Wardha, 61,212; Bhandara, 68,950; Chanda, 82,533; Jabbalpur, 43,913; Balaghat, 28,358; Saugor, 23,970; and Damoh, 22,082. In *Berar*:—Wun, 46,129; Buldana, 19,563; Akola, 15,097; and Amraoti, 11,317. The balance in both instances on the total areas given is made up by districts with smaller acreages than those shown.

and Berar.

Chief
Districts.

Sir J. B. Fuller, in a *Report on the Outturn of Crops* (1894, 20–2), furnishes many useful particulars regarding linseed. "Thirty years ago," he says, "the production of linseed was relatively very small. It is now one of the principal of agricultural resources of the Provinces, and crop statistics indicate that the area is still extending. But there is reason to believe that the land rapidly becomes linseed-sick, when it requires a long period of rotation." "By far the most important producing tracts are the Nagpur and Chattisgarh plains. In the former it is almost entirely a single crop. In the latter it is of most importance as an after crop, though its growth as a single crop is by no means insignificant." "The crop would be exceedingly profitable were it not very precarious. In a good year it gives a larger return than wheat with a far smaller outlay on seed and cultivation. But the plants are very sensitive to damp when in flower, and a few days' cloudy weather at this time will prevent the seed from setting and bring a promising crop to a disappointing harvest. Rust also causes great damage." The late Dr. Barclay (*Agri. Ledg.*, 1895, No. 20, 267–70, 351–2) devoted much attention to the study of that fungal parasite. While by no means confined to the Central Provinces and Berar, it has been specially studied in connection with these provinces, and a reference to the available information may therefore be given in this place.

Outturn.

Precarious.

Rust.

The methods of cultivation and all other details are precisely similar in the Central Provinces to those already described under Bengal and Bombay, and need not therefore be here repeated. Subsequent years to those discussed by Sir James Fuller have manifested an even greater expansion, though severe fluctuations and heavy losses through failure of crops were also recorded. About 5 per cent. of the total cropped area in the Central Provinces is ordinarily under linseed. It cannot be grown more frequently than once in five or six years but it has this advantage, that when wheat and gram give bad returns, linseed, in such seasons, is usually successful, and thus may save the cultivator's position. When cotton or *juar* fail, the land may be suddenly thrown under linseed and a good crop obtained. When grown as a sole crop, linseed is ordinarily sown earlier than wheat, and this is sometimes in its favour. But a large part of the linseed produced is sown as a second crop following rice, and is thus much later. An early cessation of the monsoon would thus injuriously affect the late crop.

Relative Area.

Wheat
versus
Linseed.

Trade in Central Provinces.—The bulk of the production in these provinces is conveyed by train to Bombay, but a fair amount is imported from Rajputana and Central India.

To Bombay.

3. **UNITED PROVINCES.**—The two provinces of Agra and Oudh viewed together undoubtedly take the third position in the Indian production of linseed. During 1905–6 the area in the former came to 185,034 acres and in the latter to 60,880 acres, or a total of 245,914 acres. And to indicate the distribution the following figures of the district areas may be recorded, In *Agra Province*:—

Agra and
Oudh.

crop is in good seasons ripe by February, and is reaped with a sickle near the ground or uprooted. It is then carried to the threshing-floor and dried, when the seeds readily separate, and are winnowed in the usual way. A full crop may be 500 lb. to the acre, but it is precarious, and often may yield much less. Linseed may therefore, be considered a delicate crop, which in favourable seasons only is grown with particular success.

Trade in Bombay.—The port town of Bombay drains its supplies from the Nizam's Territory, Bombay, the Central Provinces and Berar, Rajputana and Central India, the United Provinces of Agra and Oudh, the Panjáb, and Madras. In the returns of traffic carried by rail and river, it is shown that the town of Bombay received in 1904-5, 4,561,058 cwt.; in 1905-6, 2,586,494 cwt.; and in 1906-7, 1,936,053 cwt. The most important contributing single centre is the Nizam's Territory. From these supplies are, of course, drawn the Bombay exports to foreign countries, and it is thus instructive to note that one-half comes from the Nizam's Territory—a region very different from that from which Calcutta drains its supplies.

5. **PANJÁB.**—Since the time that Baden-Powell wrote his *Panjáb Products* (i., 497-500, 522-5) and Stewart published his *Panjáb Plants*, a considerable expansion of the area of linseed seems to have taken place. Still, the total area in 1905-6 was only 31,293 acres, the bulk being in Kangra, 12,580 acres; Gurdaspur, 4,039; Sialkot, 3,624; Ambala, 1,575; Hoshiarpur, 1,927; Gujrat, 1,579; and Jhelum, 1,309. In Kashmir there is also a fair area, the plant being cultivated up to about 6,000 feet above the sea (Lawrence, *Assess. Rept.*, 1890, 18). The imports into the Panjáb of linseed obtained from Kashmir is an important item in the Trans-frontier trade, and one of increasing value. In 1898-9, these imports were 20,423 cwt., valued at Rs. 88,952; in 1901-2, they had become 223,642 cwt., valued at Rs. 15,52,993; and in 1903-4 stood at 50,502 cwt., valued at Rs. 3,35,136; but in 1906-7 fell to 6,083 cwt., Rs. 41,189. In 1860-3 a company carried out fairly extensive experiments at Sialkot in order to ascertain if flax could be there produced; they were apparently unsuccessful, for the plant presently grown in that district is entirely for linseed. In Kangra the seed is thrown among the stubble after cutting the rice and springs up without any special cultivation; it is thus a second or supplementary crop.

6. **HYDERABAD, CENTRAL INDIA AND RAJPUTANA.**—It is unfortunate that particulars cannot be ascertained regarding the production in the Native States, since one or two of these, more especially Hyderabad, are important centres of production. The only sort of conception that can be obtained regarding this, is by a study of the railborne traffic. During the year 1904-5 the Nizam's Territory exported 1,226,202 cwt., and in 1906-7, 850,037 cwt.; Rajputana and Central India, 951,460 and 182,170 cwt. in the same years; these amounts, going to Bombay, constituted fully one-half of the Bombay supply.

7. **MADRAS, ASSAM AND BURMA.**—These provinces take so small a share in the Indian linseed traffic that they can be neglected without serious consequences. The reports from the province of Eastern Bengal and Assam were in 1904-5, 85,746 cwt., and in 1906-7 only 45,893 cwt.; of Madras still less, namely 50,171 and 31,269 cwt.

INDIAN TRADE IN LINSEED AND LINSEED OIL.—In the provincial paragraphs above, mention will be found to have been made of the extent of cultivation and the supply of linseed obtained from the chief producing provinces. It is not necessary to repeat these statements, but a good starting-point in a study of the total linseed trade of India is naturally to be had in the figures of FOREIGN TRADE.

British Gift to Indian Cultivators.—**FOREIGN EXPORTS.**—Royle informs us that the first mention of the EXPORTS of linseed from India occurs in 1832, when 3 cwt. were recorded. The very next year the exports were 1,583 cwt.; in 1839, 120,922 cwt.; and in 1850, 560,452 cwt. In 1860-1 the exports from India were 550,700 cwt., valued at Rs. 1,25,57,790; in 1880-1, 5,997,172 cwt., valued at Rs. 3,69,81,265; in 1900-1, 5,060,189 cwt., valued at Rs. 4,45,60,096; in 1903-4, 8,616,356 cwt., valued at Rs. 5,74,41,762; and in 1904-5 they

attained their highest record, namely 11,182,009 cwt., valued at Rs. 6,32,87,256, but sank in 1905-6 to 5,788,860 cwt., valued at Rs. 4,11,55,398, and in 1906-7 still further to 4,378,826 cwt., valued at Rs. 3,25,98,578. The linseed consumed in India represents only about 5 per cent. of the production, hence it is not far from correct when it is affirmed that the traffic as known to us to-day is entirely a consequence of the British administration—a gift to the agriculture of India which covers an area of land, profitably utilised, of approximately four million acres, and gives a production of half a million tons of oil-seeds, which represents a contribution to the earnings of the farmers of three and a half million pounds sterling. Moreover, it is a crop that may be used as a safety-valve, and be increased or decreased according to the owner's advantage. In other words, land is thereby profitably cultivated, in excess of ordinary food necessities, which may be thrown under food crops as occasion arises. But for these very reasons, the traffic is subject to the greatest possible variations. Production depends greatly on local necessities of food, the prices ruling in Europe for linseed, and the relative values of linseed and cotton for the time being. The Argentine Republic has within recent years become India's most formidable rival.

Out of the total exports in 1904-5, India's record year (total 11,182,009 cwt.), 3,885,776 cwt. were consigned to Great Britain; 2,746,965 cwt. to Germany; 1,889,846 cwt. to France; 1,173,647 cwt. to Holland; and 673,874 cwt. to Italy.

Linseed, like wheat, is very readily influenced by the vicissitudes of bad seasons, caused either by drought or blight. But so important a position has the Indian supply secured in the markets of the world, that when the quantity decreases the price, as a rule, rises, thus compensating the producer. But perhaps the most instructive lesson to be learned from the study of the areas of production of linseed, in relation to the returns of foreign exports, is the circumstance that while linseed holds the third position in area, the value and quantity of the seed exported from India are usually very nearly the values and quantities of all the other oil-seeds taken together. And from this standpoint alone, therefore, is derived a fairly tangible conception of the consumption of oils and oil-seeds within India itself, and full confirmation obtained of the statement already made that linseed is grown primarily for the purpose of export: it is a rent-paying crop.

Internal Trade.—The returns published officially regarding the movements of linseed by road, rail and river afford the only really definite conception of production and sale that can be learned. The traffic registered as carried by these routes during the five years ending 1906-7 were, 1902-3, 5,922,967 cwt.; 1903-4, 8,884,004 cwt.; 1904-5, 12,051,507 cwt.; 1905-6, 5,278,659 cwt.; and 1906-7, 4,859,773 cwt. Analysing the record year (1904-5), the total shown under foreign exports (disregarding for the moment the traffic in the oil) came to 11,182,009 cwt., or say half a million cwt. less than the deliveries registered by the railways at the port towns—and that surplus may, therefore, be taken as the amount used up by the local mills or carried forward into next year's stock. A certain discrepancy has, however, to be accepted, due to imperfections in the returns and unavoidable duplications. Still, it can fairly be said that the figures compiled by one department (Railways) provide the exact quantity shown by another (Foreign Exports), and a third line of reasoning might

be used to confirm both, namely the area of cultivation expressed to the accepted average yield. Viewed from any and every standpoint, we learn that the linseed of India is grown purely and simply in obedience to a foreign demand. As already mentioned, the exports from Calcutta are drawn from the province of Bengal (two-thirds) and from the United Provinces (the remainder); Assam and the Central Provinces contributing between them only about 120,000 cwt., out of a total Calcutta supply of close on 7,000,000 cwt. The exports from Bombay, on the other hand, are drawn from the Nizam's Territory, Rajputana and Central India, the Central Provinces and Berar, and lastly the Bombay Presidency itself, and in the order named. Of the producing provinces (judged of from the railway returns), Bengal heads the list, and is followed by the United Provinces (a good second); by the Nizam's Territory (an indifferent third); by the Central Provinces and Berar (a very poor fourth); then Rajputana and Central India; Bombay; next Assam; and, last of all, Madras. Karachi exports a small amount of Panjáb linseed. Seeing that the Central Provinces have so large an area under the crop, their position as fourth in exports is a little difficult to understand. The explanation is perhaps that the area is shown larger than it should be owing to mixed cultivation being estimated as pure.

Exports.

Linseed Oil and Oil Mills.—It cannot be ascertained how many of the 99 oil mills, reported to be at work in India, are concerned in the linseed traffic proper. Only one appears to deal exclusively in linseed, namely the Gourepore Company, Ltd., near Calcutta. Their oils and oilcakes are noted all over India. The mill, moreover, produces both boiled and unboiled oils. The exports of linseed oil from India are not very important, nor do they appear to be increasing; in fact, judged of by the returns from 1899-1900 to 1906-7, they have, if anything, been decreasing. In 1899-1900 they were 248,479 gallons, valued at Rs. 4,20,167; in 1903-4, 137,952 gallons, valued at Rs. 3,61,654; in 1905-6, 186,682 gallons, valued at Rs. 4,57,983; and in 1906-7, 114,205 gallons, valued at Rs. 2,18,926. Nearly the whole of these exports go from Bengal, and thus to a large extent doubtless embrace the Gourepore Company's transactions. It is also noteworthy that the major portion goes to Australia and New Zealand. As already mentioned (p. 726) the cake is valued as an article of cattle food when not adulterated with mustard (see pp. 184, 770, 817).

LIV TOCK F INDIA.—This very large and important subject may be discussed under the following sections: Oxen and Buffaloes; Sheep and Goats; Horses, Donkeys, Mules, Camels; and Pigs.

Live tock.

An analysis of the returns of Live Stock in India during 1905-6 manifests the existence of approximately 198 million head of cattle (cows, bulls, bullocks, buffaloes, sheep, goats, horses, mules, donkeys, camels, etc.). The actual figures are 30 million bulls and bullocks, 22 million cows; 13 million buffaloes; 26 million young stock; 18 million sheep; 25 million goats; 2½ million horses, donkeys, mules; and 393,308 camels. live stock of Bengal is not recorded, but, since its population is twice that of Madras, it may be assumed to possess double the returned live stock of all sorts met with in the Southern Presidency, viz. 61 million. This gives the 198 millions (above mentioned) as the total live stock, in place of the official figure of 137 millions (exclusive of Bengal). But to that total has also to be added the 15 millions shown as owned by the Native States. In fact 30 millions would not over-state the live stock of these States, making a grand total for India of over 228 million cattle of all kinds.

Some such estimate seems essential to allow of comparison with the trade returns, which include Bengal and the Native States. Thus, for example, the term "hides" may be taken to mean undressed skins of full-grown bovine animals, and "skins" those of calves, sheep and goats. For the five years ending 1903-4 the average number of hides (raw and dressed) exported from India came to 12½ millions, and of skins 37 millions; these collectively would, therefore, show 23 per cent. on the estimated total live stock of all India for the period in question. But the exports by themselves take no cognisance of the numbers of hides and skins used up by the indigenous leather industries of India itself, nor of the numbers of animals that die or are killed and the skins, for various reasons, entirely lost. Were a figure to be given for the annual death-rate (from all causes) of the cattle, sheep and goats of India, it is probable that it would be something nearer 70 to 80 rather than the 50 millions indicated by the returns of foreign trade specially dealt with above. For further particulars see the article *Hides and kins* (pp. 632-9).

I. THE OXEN, BUFFALOES, ETC., OF INDIA.

The following is a list of the chief Bovine animals of India that fall into this group:—

as *Indicus*, *Linn.*; *Blanford, Fa. Br. Ind. (Mammalia)*, 483-4; *Mollison, Textbook Ind. Agri.*, 1901, ii., 63-139; *Meagher and Vaughan, Dairy Farming in India*, 1904, 41-7. The Zebu or Humped Ox, *bail, gair, gau, dhür* (cattle), *dhür danger* (horned cattle), *dudhar* (milk cow), etc.

The Indian animal differs from the tame ox of Europe and North Asia in structure, general coloration, voice and habit. Its origin is unknown, but according to Blyth it was probably African. No ancestral form has as yet been discovered among the Indian fossil bovines. Humped cattle have, however, often been reported to have run wild in India. All the breeds of the Indian ox are held sacred by the Hindus and are, therefore, neither killed nor their flesh eaten by a large portion of the people. On the other hand, the tending on cattle is regarded as a highly honourable position, and hence also milk, butter, cheese, etc., are largely consumed by all classes of the community. Below will be found a brief sketch of some of the leading breeds of oxen.

. *ubalus*, *Linn.*; *Blanford, l.c.* 491-3; *Mollison, l.c.* ii., 140-55; *Meagher and Vaughan, l.c.* 47-51, 56; *Note on Export of Buffalos to Australia, Rev. and Agri. Dept. Ind.*, 1885. The Buffalo, *arna, mang, mains, bhains, bir biar, gera erumi, moh, siloi, misip, iroi, kywai, pana, karbo*, etc.

Tame buffaloes are found all over the plains and lower hills of India. They are repeatedly mentioned in the *Institutes of Manu* (xi., 69), so that they have been known from the earliest historic times. They are semi-aquatic animals, and accordingly most abundant in humid localities. Are large, massive, and clumsy creatures, with exceptionally short thick legs and conspicuous hoofs. The horns are thick, flat, curved or straight, and marked with rings indicative of age. The muzzle is large, remarkably square, and the head carried very low. A truly wild buffalo is fairly abundant in India (except in the Southern and Western Provinces), especially in low-lying swampy land covered with tall grass. Few domestic animals have, in fact, changed less than the buffalo. While it will not breed with the ox, the tame buffalo-cow will pair readily with the wild buffalo-bull, the stock being thereby improved,

WILD SPECIES

They are powerful draught animals, and the milk is exceptionally rich in butter-fat.

. *grunniens*, *Linm.*; Blanford, *L.c.* 490; Turner, *Acc. Emb. to Tibet*, 1800, Yak. 186, t. x. (from a picture belonging to Warren Hastings); Vigne, *Travels, etc.*, 1842, ii., 277; Hoffmeister, *Travels in Cont. Ind.*, 1848, 362, 374. The Yak or Grunting Ox, *dong*, *brong-dong*, *ban-chowr* (the wild): *yak*, *pegu*, *chour-gau*, *kotass* (the domestic animal).

In its wild state it inhabits the coldest and most desolate tracts of the Himalaya—being found at a greater elevation than any other mammal. It is dark brown, almost black, with the exception of the muzzle, head and neck, which are often grey. In domestication it becomes smaller and variable in colour, being often pure white or piebald. Mention is made of the *gatas* or “Tibetan yak” in the *Ain-i-Akbari* (1590, Jarrett, transl., iii., 121). It is kept by the Tibetans and various other tribes that inhabit the higher regions, on account of its being a sure-footed pack animal. The flesh is said to be rich, juicy and delicately flavoured. The milk is exceptionally rich (considerably richer than that of the cow), and much of the food of the people consists of curd either fresh or dried and powdered into a kind of meal. The white tails constitute the *chowris* (fly-flaps) sold all over India. The hair is woven into cloth and ropes. In fact the wealth of the people of Eastern Tibet consists in their flocks of yaks. The horns are made into cups and other objects of domestic use and ornament. But the yak breeds freely with domestic cattle. One was sent to England by Warren Hastings, which lived for some years and became the sire of many cross-bred calves, only one of which lived and was successfully crossed by an Indian bull. A cross is common on the North-West Himalaya and is known as the *dhzo*, *zobo*, etc.; it is fertile and in some localities preferred to the pure yak.

Wild Alpine Species.

Domestication.

Milk.

Chowris.

Hybrids.

Other species.—Three other animals belonging to this genus may be here mentioned, but, as scarcely of economic value, need only be exhibited very briefly:—

(a) . *frontalis*, *Lamb.*; Blanford, *L.c.* 487-9; the *Mithan* or Gayal of Assam, Manipur, Naga hills, Chittagong and Burma. Said to be partly domesticated by the Kukis.

Mithan.

(b) . *gaurus*, *Ham.*; Blanford, *L.c.* 484-7; the *Gaur* or Indian Bison of the hilly forests of the Indian Peninsula, Assam, Burma and the Malay Peninsula, ascending to altitudes of about 6,000 feet. It has occasionally been tamed by the people on the hill tracts between Assam and Burma, but has never, strictly speaking, been domesticated. The horns are in great demand for ornamental work. (See Horn, p. 646.)

Bison.

(c) . *sondaticus*, *Müller & Schley.*; Blanford, *L.c.* 489-90. The Banting, found in Burma and the Malay Peninsula, Borneo, Java and Bali. It has been more or less domesticated in Java and perhaps elsewhere.

Banting.

CATTLE AND CATTLE-BREEDING.—In Europe cattle may be said to be reared for milk and meat, but in India their chief value is as beasts of burden. Horses are all but unknown in Indian agriculture, the bullock being very nearly exclusively used for tillage and transport. Occasionally camels are so employed and buffaloes are highly valued for their milk, though they are too slow to be much in demand for agricultural operations.

Cattle-breeding.

There are many breeds of indigenous cattle. Nearly all the pure stocks are of one colour—white or grey. In areas where little attention is paid to the subject, mixed colours or piebald cattle are not infrequent. Except in the north-east of Madras, all Indian cattle are horned. The hump is prominent, and more highly developed in some breeds. Bullocks which are suited for slow and heavy work have usually massive heads, long pendulous ears, thick short necks, coarse leg-bones, big feet, much loose skin on the neck, dewlap and sheath, and no particular droop in the hind quarters. Those best suited for quick work have clean heads, fiery tempers, short erect ears, thin necks, compact rounded bodies, small hard feet, a very decided droop in the hind quarters, and little or no loose skin on the neck, dewlap and sheath. Indian oxen, it may thus be observed, are distinguished collectively from the breeds of

Pure Breeds.

Heavy Workers.

Quick Workers.

Hump.

Europe by the hump on the shoulders, by the deep undulating dewlap, and by the short grunt in place of the ringing bellow of the European ox (*Imp. Gaz.*, iii., 77-89). Many European travellers in India allude to the "hump" as a special feature of the provisions (beef) procurable in India. Thus Terry (*Voy. E. Ind.*, 1622 (ed. 1777), 89-90) says the "beeves" differ from ours in being smaller and in having "each of them a great bunch of grisly flesh which grows upon the meeting of their shoulders." He then adds that the flesh is very sweet and tender.

Most Sacred of Animals.

There are few subjects in which India is so very backward as those of Cattle-breeding and Dairy Farming, hence the available literature is comparatively insignificant and defective when judged of in the light of their importance. This is the more surprising since, with a large proportion of the people of India, the cow is the most sacred of all animals. In the *Ain-i-Akbari* (1590) special mention is made of the veneration in which it is held. Linschoten (*Voy. E. Ind.*, 1598, i., 257, 300), Bernier (*Travels*, 1656-68, in Constable, *Or. Misc.*, i., 326-7), Tavernier (*Travels Ind.*, 1676 (ed. Ball), ii., 217), and many other European travellers in India, dwell on the sacred character of the Indian cow. It might naturally, therefore, have been expected that the cow, and some at least of the products it affords, would have existed in even a higher or more fully developed condition than is the case in most other countries.

Climatic Influences.

While there are certain Indian breeds of cattle that compare favourably with those of other parts of the world, most are inferior in size and strength as well as in quantity of meat and milk which they provide. The breeds vary directly with the soil, climate and food of the countries in which they live. For example, in deltaic tracts the oxen are inferior but the buffaloes superior. Meagher and Vaughan very rightly observe:—"The great variations in the Indian climate largely affect the milk yield of cattle imported from foreign districts. Hansi-Hissar cows will not prove as satisfactory say in Jabbalpur, as they will in Delhi or Meerut, and this should be borne in mind before condemning the Hansi-Hissar breed. It appears to be a fact that the further they travel east or south (*i.e.* the damper the climate becomes), the more certain is the decrease in the yield." Climate, soil and available food in fact influence so rapidly the breeds of cattle that it becomes undesirable to extend schemes of improvement very much beyond selection from existing stock within each area.

Local Selection.
Foreign Strains Undesirable.

Indeed for the plains of Lower India, crosses of foreign strains, more especially from Europe, have proved highly unsatisfactory. The chief difficulty is to overcome the opposition that exists in transferring, without loss of special merit, the stocks even of one part of India to another. If the intention be to improve, as heavy draught animals, the breeds of the Panjáb, Gujarat and Mysore afford ample material: if the desire be for swiftness, the trotting bullocks of the Central Provinces and of South India (*gainis*) are unsurpassed anywhere: and, if milch-cows be sought, there are several famed breeds, such as the Nellore or Ongole and the Gir of Kathiawar and the Hansi-Hissar of the Panjáb. In the *Ain-i-Akbari* (Blochmann, transl., 149) special mention is made of the Gujarat breed of cattle and of the small swift-footed *gainis*. This is curiously confirmed by Ralph Fitch (in *Purchas' Pilgrimes*, 1625, ii., 1733), who, while telling of his visit to the Emperor Akbar in 1585, specially mentions the carved and gilded carts of Agra and Fatehpur drawn by "two little bulls

Draught Animals.

Trotting Bullocks.
Milch-cows.

Fitch.

about the bignesse of our great Dogs in England." [Cf. Tavernier, *l.c.* 44; Terry, *l.c.* 144-5, 187.]

But, excepting at the homesteads of the wealthy or at the experimental farms owned by Government, special selection of stock or the rearing of healthy, well-formed bulls for service purposes is practically unknown from one end of India to the other. The story told by Abul Fazl of the "Cow Stalls" kept by the Emperor Akbar reads more like a proclamation of the pageant of the all-wise and good Emperor than a statement of his efforts towards the improvement of the cattle of India. The Amrit Mahal breed is said to have been introduced into Mysore and specially developed by Haider Ali for military purposes. But history tells of no Hindu Prince who devoted anything like the attention Akbar bestowed on this most important subject.

Indian agriculture has for centuries been and is to-day essentially a peasant industry. It is in the hands of persons who have the traditional knowledge of their ancestors to guide them, but absolutely no capital beyond that absorbed in daily necessities. Each person, as a rule, keeps but two or three cows, and cannot afford to keep a bull. And moreover, since the male offspring are not generally emasculated until they are three years old, the cows are served by immature and as often as not diseased, degenerated or otherwise undesirable males. Improvement of the breed under these conditions is naturally very difficult. For some years past, however, the Government of India have recognised the obligation of initiating a reform, and with this in view have had superior bulls reared at special farms (such as those of Hissar, Charodi, Pusa, etc.) and presented to districts where it was desired to improve the local breed of cattle. Voelcker alludes approvingly to this action, and urges that the satisfactory results attained should be pushed forward until the remotest corners of the Empire have been reached. So also the Government have aided very greatly by encouraging local fairs and cattle shows, by awarding special prizes on the verdict of high expert officials who have been deputed to visit the shows for that purpose. But it is well known that half-bred cattle contract rinderpest and other common diseases in a most virulent form and rarely recover under treatment, while many indigenous breeds are comparatively immune. This has accordingly led to belief that the best results are likely to be obtained by breeding strictly within carefully selected and special local stocks, not promiscuous inter-breeding of all races.

(4) **Chief Breeds of Indian Buffaloes.**—The breeds of buffaloes have not as yet been critically studied. Until this has been done, little more can be accomplished here than to indicate those most frequently spoken of. Terry gives a curious reference (*Voy. E. Ind.*, 1622 (abrid. ed. Havers), 1665, 359) to "a very large beast having a smooth thick skin without hair called a buffalo which gives good milk; the flesh of them is like beef but neither so toothsome nor wholesome."

In rice-growing tracts buffaloes are extensively used for tillage and cartage work. But although they thrive well in wet climates, the best breeds are met with in localities of moderate rainfall and under the conditions best suited for cattle-breeding. But buffaloes must have access to water, and require to be bathed once or twice a day if they are to be kept in health. It is also customary to clip off their sparse coat of hair once or twice a year. Buffaloes vary in colour, but the majority have black, shining

skins. Some have white markings and a few are grey, light dun or white. Their lowing differs from that of kine and they have no hump. Most writers allude to the fact that it is difficult to get a good buffalo-bull, owing to its being less valuable than the buffalo-cow. The bulls are not often reared, but are either purposely starved or killed. They attain maturity at 3½ years and are used for stud purposes for not more than 7 or 8 years. "It is just as essential when starting a dairy, to get a good bull as to get good cows, for many authorities now hold that it is from the sire, and not so much from the dam, that a heifer inherits her milking powers." Middleton, who has kindly perused this review of Indian information, observes that the milking properties may be transmitted by either sex equally, but in England bulls are usually more carefully bred than cows and may so transmit properties with greater certainty.

Considerable commercial interest is taken in the shape of the buffalo-horn, the straight forms being of greater value than the curved. From the standpoint of the dairy farm, the breeds with curved horns are apparently the most highly appreciated. The following are mentioned by authors as the characteristics by which the chief breeds of buffaloes may be classified:—those with horns approaching a circle (the *spirocerus* of Hodgson), and those with the horns long, straight, the tips only arching forward (the *macrocerus* of Hodgson).

1. Delhi.—The breeds of the United Provinces, the Panjáb and Sind are often collectively designated "Delhi Buffaloes." The horns are short, thick at the base, sharply angled, and rise from the head in a backward and upward course, then become completely curled up like the horns of a ram. According to Meagher and Vaughan (l.c. 47-8) the best buffaloes of this kind are the *murrah*, procured in Hansi-Hissar, Rohtak, Jhind and Nabha. The name given to them is derived from *murna* (= to turn), and is an allusion to the form of the horns. They are sometimes also called *kundi*, and cross-breeds with this and the inferior village buffalo (with straight horns) are called *dogla*. [Pease, *Agri. Ledg.*, 1895, No. 22, 408; Hadi, *Agri. Ledg.*, 1895, No. 12, 206-8.]

2. Surat and Deccan.—The buffaloes of Surat and the Deccan are very different. They both have what are called straight horns. That is to say, in the Surat animal they extend along the side of the neck, then turn up near the shoulder with an inward graceful curve; and in the Deccan breed are even straighter, and extend backwards to the shoulders before becoming arched.

3. Jafferabad.—In the Jafferabad (Kathiawar) buffalo the horn is very massive and coarse. It is flat and broad below, developed at first downwards and backwards, then curved forwards, thus forming three-quarters of a circle, placed on either side of the head. But there is still another peculiarity. The frontal bone becomes greatly developed until it causes the horns to appear united across the forehead. This is a very large, clumsy animal with unusually long legs and large spreading feet.

4. D -coloured Buffaloes.—Here and there all over India, more especially in hilly districts, remote from swampy country, a dun-coloured buffalo is met with that seems very distinct from the other breeds. This has by zoologists been regarded as possibly a distinct variety, and has received the name of *B. bubalus*, var. *fulvus*. Meagher and Vaughan say these dun or brown buffaloes generally start well but end badly. They are not as a rule heavy milkers for any length of time.

5. Burma and Assam.—Varthéma (*Travels*, 1510 (ed. Hakl. Soc.), 200-1) speaks of the breeds of Tenasserim as very "misshapen." Many subsequent writers have incidentally mentioned the buffaloes of Burma, but no one apparently has studied them comparatively with the breeds of India. Evans (*Agri. Ledg.*, 1895, No. 10, 165-72; 1896, No. 10) gives, however, many particulars of the Burmese breeds. They would seem to have long, so-called straight horns, like those of Surat. They give very little milk. The buffaloes of Assam have been discussed in some detail by Darrah (*Agri. Ledg.*, 1894, No. 14). He tells us that though the stock is regularly imported from Bengal, the animals soon prove on the rich pastures of the Brahmaputra valley.

(B) *Chief Breeds of Indian Cattle*.—Very little strictly speaking of a scientific nature has as yet been published on this subject. Wallace and Voelcker have each given the results of their rapid tours of inspection through India, and numerous local writers have extolled the merits of certain breeds with which they were familiar. No one has as yet critically and comparatively examined all the breeds of India. Little more, therefore, can be here attempted than to amplify the particulars of the chief breeds (given in the *Dictionary*) in the light of the additional information brought out by the various writers in *The Agricultural Ledger*, and by Mollison in his *Handbook* and by Majors Meagher and Vaughan in their *Dairy Farming in India*, etc.

1. **Gujarat**.—These are the indigenous cattle of the plains, Ahmedabad, Kaira and Baroda, also the hilly countries of Palanpur and Deesa, where a large breed of very superior animals exists. They are, in fact, the finest cattle of India for general agricultural purposes. In the more southern portions of the province, however, a mixed and inferior breed occurs which in many respects resembles the Deccani cattle. The larger and superior race is in colour from white to bluish-grey, the head, neck and limbs often being of a darker tint than the body. The horns are somewhat bowed and curve outwards as they leave the skull, then upwards, and lastly inwards. The animals are tall and somewhat leggy, but very powerful, and for draught purposes, especially when crossed with Mysore, are very valuable. [*Cf. Ovington, Voy. to Suratt, 1689, 253-5, 273-85.*]

Draught Cattle.

2. **Gir or Kathiawar**.—This breed is specially noted for its milk-giving powers. It is extensively reared in herds in the Gir forests and hills of South Kathiawar. They are coloured animals, often speckled or "roan," in various shades of red and brown. The long, pendent lop-ears and short crumpled horns are striking peculiarities. In Bombay they are generally called "*Surtis*," because brought *viâ* Surat.

Gir.
Milch Cows.

3. **Sind and Aden**.—This small-sized animal is powerful though lazy, but the cows are remarkably good milkers. The horns are short, thick, blunt-pointed, and project outwards and upwards. The best are bred within a radius of 30 or 40 miles from Karachi, and chiefly on the lower hills, where good grazing is to be had. The breed may, however, be met with through Rajputana and the Southern Panjâb. [*Mollison, The Montgomery and Sind Breeds of Cattle, in Agri. Journ. Ind., 1907, ii., pt. iii., 252-6.*]

ind.

4. **Deccan, Kh. desh and Southern Maratha Country**.—It cannot be said that the regions indicated have developed any very special breeds of their own. Large portions of the country are subject to periodical scarcity and occasional famine, and the animals have become hardened and thus acquired their chief characteristic. The dewlap is inconspicuous, the forehead narrow and the muzzle large, while the horns spring in an upward direction, then bow abruptly outwards and ultimately inwards. The cows are poor milkers, and the bullocks, though small, are extremely active and have great powers of endurance, if not given too heavy a task. They are accordingly much used in light carts or as trotting bullocks. So long ago as 1503, Vertomannus (in *Hakl. Voy.*, 1811, iv., 577), speaking of the Deccan, said, "It hath innumerable kyne of shynynge yelow."

Deccan.

Trotting
Bullocks.

5. **Mysore and Coorg**.—The cattle of this region are celebrated both for their swiftness and for their spirit and powers of endurance. If cattle-breeding could anywhere in India be viewed as having attained the position of a recognised principle of agriculture, to Mysore would have to be assigned that honour. Two descriptions exist side by side, each serving its own particular purpose. The first and by far the most numerous is the *naludana* of the villages. This is the agricultural stock and main source of the dairy produce of the State. The second is the *doddadana* or big cattle. This embraces the following special breeds:—*Amrit Mahal*, *Hallikar*, *Chittaldurg*, *Mahadeswara*, *Betta*, etc. The first mentioned—the *Royal Amrit Mahal*—is the most highly prized, but is neither the largest nor the most powerful. These splendid animals are capable of performing quick journeys of long distances with a light and moderate load. They are large and powerful animals, chiefly kept by the well-to-do. The finer breeds are pure coloured, the inferior often mottled. There is no extra development of the dewlap to interfere with their trotting action. Their eyes are deep-set, the forehead bulges above the eyes and slopes backward. The ears are short and pointed,

Mysore.

Agricultural.

Active and
Powerful.

and the horns, which spring close together, take a backward sweep, gradually diverge, and near the extremity curve gracefully upwards and forwards. They are all, even the *nadudana* breeds, powerful draught cattle but poor milkers. [Cf. Buchanan-Hamilton, *Journ. Mysore, etc.*, 1807, i. (many passages); Kristnamangar and Pease, *Cattle of Mysore, in Agri. Ledg.*, 1895, No. 24; Kristnasamiangar, *Diseases of Mysore Cattle, Agri. Ledg.*, 1896, No. 28.]

adras.
Milch Cows.
6. **adras, Nellore, Kistna (Ongole), etc., Cattle.**—The Ongole breed of cattle is reared chiefly in the districts of Nellore and Kistna. From early times it has enjoyed a well-earned reputation of being one of the best milking breeds of India. Most writers agree, however, in saying that they degenerate rapidly when removed to other localities. The valleys of the Kistna and its tributaries have a rich, soft, deep black soil, and naturally therefore the cattle of such a country are not well suited for hard roads, unless carefully and regularly shod. They are collectively heavily built animals, docile and of a mild and gentle disposition—essential qualities for milch-cattle—but sluggish in action. The head is erect on a short, stout neck. The horns are short and stumpy, somewhat resembling those of Sind cattle, and longer in the cows than in the bulls. They give to the head a curious and characteristic appearance, the bulging forehead forming a very obtuse angle. The prevailing and true colour is white with grey or black points, and frequently the bulls are black about the neck and shoulders—broken colours indicate impurity. In point of size they are inferior to the Gujarat and Nagar cattle. Other Madras breeds are the Alambadi of Salem and Coimbatore; the Baragur of the hills of Coimbatore; the Kangayam of Madura; the Palikolam (Jellicott) cattle of Madura; the small Trichengodi cattle of Salem; the artificially spotted cattle of Tanjore; and the Punganur cattle of North Arcot. [Cf. Pease, in *Agri. Ledg.*, 1895, No. 7; Sabba Rao, in *Agri. Ledg.*, 1896, No. 12; Holmes, *Hair-markings on Horses and Cattle, Dept. Land Rec. and Agri. Mad. Bull.*, 1900, No. 42; also *Notes on Cattle of Madras Pres.*, *Bull.* No. 44; Gunn, *The Nellore Breed of Cattle, in Agri. Journ. Ind.*, 1906, i., pt. iii., 237–42.]

urma.
Well-cared for.
7. **Burma.**—Very little has been written regarding the cattle of Burma, so that it is not possible to assort them with the Indian breeds. Red is the dominant colour. The horns, when not interfered with, take an upward and forward direction and grow to a length of 10 to 18 inches. The neck is short and powerful and the dewlap not much developed. The Burmans are most considerate of their cattle, never overworking them, and grooming them carefully on the close of the day's task. The animals are also well-fed, so that they are naturally much superior to the imported cattle from India. But as milk-producers the Burman cows occupy a very low place, owing to the prejudice entertained by the Burmans against the use of milk. [Cf. Frost, *Note on Cattle of Burma*, 1889; also *Quart. Journ. Vet. Sc. Ind.*, 1890; Evans, in *Agri. Ledg.*, 1895, No. 10; *Rept. Rev. Admin.*, 1889–90, 47–8; *Settl. Repts* (many); also *Dept. Agri. Ann. Repts.*, etc.]

engal.
Sacred Bulls.
8. **Bengal and Assam.**—The ordinary village cattle of these provinces might practically be spoken of as the most inferior in India. They are small overworked and half-starved animals of which little more can be said than that they are suited to the climatic conditions and soils of the countries in which they live. In certain localities, such as Bihar and Tirhut, considerably better breeds exist, most probably a consequence of the continual importation and crossing of fresh stock. In Gaya, for example, it is not uncommon to find an animal supposed to have been derived originally by crossing the Indian cow with an English “short-horn” bull imported in 1857. “Bihar is overrun with *pols* (bulls dedicated to the gods). These are very fat, and comparatively useless for stock purposes, but do much harm in eating and trampling the growing crops.” [Cf. Buchanan-Hamilton, *Stat. Acc. Dinaj.*, 221–8; also in Montgomery Martin, *Hist.*, etc. (many passages); Banerjee, *Bankipore Cross-bred Cattle, in Agri. Ledg.*, 1895, No. 25; Darrah, *Cattle of Assam, Agri. Ledg.*, 1894, No. 14; Mukerji, *Bengal Cattle, Handbook Ind. Agri.*, 1901, 578–93; *Imp. Gaz.*, iii., 77–89.]

C. Prov.
Nimar.
Arvi.
9. **Central Provinces.**—The stock is often very mixed. In Nimar, red and brown coloured animals prevail, and in other districts white predominate. The Nimar is, however, generally held to be the best breed. It is a medium-sized animal. Mollison says that it may be recognised by two peculiarities in the colour of the skin and shape of the horns. They are red or brown mottled, but the red is always light, sometimes almost yellowish, and the white markings are never pure white. The horns are thick at the base, blunt, flattened and curled over the head like those of the Delhi buffalo. They are chiefly valued for agricultural work and as draught bullocks. The Arvi cattle of these provinces closely

resemble those of Nellore. The bullocks are strong, but not active. [*Cf. Repts. Land Rev. Settl.* (many districts); Trydell, in *Agri. Ledg.*, 1898, No. 18; *Ann. Repts. Dept. Agri.*; *Exper. Farm Repts.*, etc.]

10. United Provinces of Agra and Oudh.—Throughout Oudh, the *nānpārā* breed ranks high. But there is a sub-breed known as the *risia*, which is smaller in size, more leggy and quicker tempered than the *nānpārā*. The horns in both are elegant, thick below, and tapering to a fine point. One important feature is a slight but distinct depression on the forehead which makes it easy to distinguish the Bahraich from the Doab and Mathura (the *kosi*) cattle. The cows of Kosi and Chhata are celebrated for their milking qualities, and the bullocks have the reputation of being good draught animals (see No. 13 below). The breeds of Kheri are, however, far superior to those of Bahraich, and much resemble the Malvi of Central India and Rajputana. In fact Kheri occupies the most prominent position amongst all the districts of Oudh, being famed for its so-called *parchar* cattle, sometimes spoken of as *bangar*. White is considered the best colour and black the worst. The bullocks are fast walkers, have a highly irritable temper, but possess great powers of endurance. Other breeds may be named:—*Bhur*, *Khairigarh*, *Majhra-Singahi* and *Dhaurahra*. [*Cf. Sayyid Mohammed Hadi, Bahraich and Kheri Cattle*, in *Agri. Ledg.*, 1895, No. 12; also *Mathura*, No. 19; *Leather, Barabanki Cattle*, *Agri. Ledg.*, 1895, No. 17; *Ann. Repts. Civil Vet. Dept.*, 1902, 2, et seq.; *Prov. Gaz.*, 1903-4 (many district accounts).]

11. Panjáb.—“It may safely be said that the best milch-cows of Upper India are obtained from the Hansi-Hissar district, and they are commonly termed Hansi cows.” With these words Meagher and Vaughan open their chapters on the “Best Milking Breeds.” Speaking of the Harriana cattle, Pease describes the region in which they are produced as “the green country which comprises about 292 villages of the Hissar district chiefly in the Hissar and Hansi Tahsils and the greater part of the Rohtak district.” The region in question has a good soil, passing into clay-loam in one direction and into sand in the other. The average rainfall is 16 inches, and the climate, therefore, is dry and well suited to cattle. But the increase of cultivation within recent years has curtailed the pasture lands and lessened the interest in cattle-rearing. Still the country indicated produces a large surplus of cattle regularly exported, as also a very important supply of *ghi* traded in all over India. The Hansi-Hissar cattle are uniform in colour: broken colours are seldom, if ever, met with. The skin is usually dark coloured and the hair white or grey, but darker at the shoulders and neck, and on the flanks sometimes almost black or blue. Red-coloured examples are rare and usually inferior. The horns are short, set wide apart and arch outwards, upwards and then inwards, but only slightly forwards. Meagher and Vaughan, while apparently accepting the Hansi as the best breed for Upper India, give several illustrations of the Sanhiwal sub-breed, which would appear to be frequently broken coloured—red or mixed colours—white being rare. According to many writers, the Montgomery cattle are powerful rivals of the Hansi for the claim of first position as a milk-yielding stock. They are small, shapely and short-legged animals with exceptionally long tails. The Director of Agriculture, in July 1903, drew up a statement of the breeds of cattle in the Panjáb, in which he adds to the above the Kuchi or Chenab breed; the cattle of the Jhang district; the Dera Ghazi Khan breeds; the Dhanni cattle of the Salt Range; and the Maja cattle of the uplands between the Sutlej and the Ravi. [*Cf. Pease, Cattle of Harriana and Sirsa, Agri. Ledg.*, 1895, No. 22; Meagher and Vaughan, *Dairy Farming in India*, 41-59; *Repts. Civil Vet. Dept.*, 1895-1900.]

12. Rajputana, Central India, Berar and yderabad.—The animals of a large portion of the tracts of country indicated naturally approximate very closely to the Hansi breed already briefly indicated. The characteristic cattle of Rajputana and Central India are invariably pure white, though grey or silver-grey specimens are occasionally seen, but broken and mixed colours are unknown. As in other large areas, there may be said to be two sub-races—a large animal specially selected and used by the well-to-do as trotting or fast walking animals, and the ordinary village or agricultural breed. Mollison calls these collectively *Malvi* (or *Malwi*) cattle, and Major Kemp speaks of the high-class animal as the *Nagore* (or *Nagar*) and the agricultural the *Rinda* (small) breed. It would seem that throughout the country indicated local names are often given which, like “Nagore,” originated from the name of a village or locality specially noted for the superiority of its cattle. Mollison observes that “the head is short, the eyes

are dark, prominent and have a docile appearance. The ears are short with little or no tendency to droop. The horns are very characteristic. They are moderately thick at the base, of fair length and are sharply pointed and invariably spring in a forward and upward direction from the head with a graceful outward bend." Prof. Wallace describes the horns as resembling two arcs of a circle set on the crest of the head with the concavity inwards. They are much prized as heavy draught animals, and are accordingly frequently seen all over Central and Western India. They are very strong, but not swift; being reared on stony ground, have hard feet and do not require shoeing even when worked on metallised roads (Col. Gerard). They are very largely bred in the territories of H.H. the Maharaja Holkar and H.H. the Maharaja Sindia and the cows are often not milked at all, and in consequence when used as milch-cows are a very inferior stock.

Nizam's
Dominions.

The Khillari cattle of the Satpura hills (in Holkar's territory extending to North Khandesh), according to Mollison, were derived originally from Mysore and should be spoken of as the Amrit Mahal breed. Mollison adds, "The fact that Khillari are now bred true to a particular type in a district where Malvi cattle are also extensively reared is a clear indication that the breeders know the advantage of keeping a good strain as pure as possible." Mr. Ali Abdoola describes four breeds, met with in H.H. the Nizam's Dominions, that take their names after the towns in which reared. Commenting on these, Vet. Major W. R. Hagger observes that from the description of the prevailing colours "some seem to have a strong strain of Mysore in them, some show a Deccani cross, while others seem to resemble the Malvi breed." [Cf. Kemp, Powlett, Reynolds, Hendley and Hagger, in *Agri. Ledg.*, 1900, No. 21; Gerard and Abdoola, in *Agri. Ledg.*, 1900, No. 22; *Gaz. Rajputana (Ajmir)*, 1904, i., A., 49-50.]

Hill Cattle.

13. iii. Cattle.—The cattle seen on the higher cultivated Himalaya are small sturdy animals with short, thick legs. They are admirably suited to the regions in which found, and are very active and wild. They are mostly black in colour, though occasionally dun or mottled examples are met with. They are well protected from the severity of the winter by a thick, shaggy coat. The hump and dewlap are hardly if at all present, and, as pointed out by Walker, they much resemble the Kerry-Dexter cattle of Great Britain and Ireland. The cattle of the lower tracts, being annually taken to the grazing lands of the Bhabar country, have been crossed with the breeds of the adjacent plains. In the higher tracts the pure hill breeds are met with, and these are spoken of by names denoting regions or special sub-breeds. The males are used for ploughing, but their working qualities are poor and many refuse to work at all, while the cows are poor milkers. In a further paragraph will be found particulars of the traffic from Nepal to the plains of India in live stock. [Cf. Walker, *Kumaon Cattle*, in *Agri. Ledg.*, 1899, No. 7; Lawrence, *Valley of Kashmir*, 358-60.]

[The following enumeration of publications, in sequence of date, may be found useful:—Thevenot, *Travels in Levant, Indostan, etc.*, 1687, pt. iii., 51-2; Buchanan-Hamilton, *Journ. to Mysore*, 1807, i., 164-6; ii., 14, 277, 382; also *Hist. iii., 407-37.
Cattle
Food and
Fodder.
Conditions of
Rearing.

CATTLE FOOD AND FODDER.—There may be said to be two conditions of cattle-rearing in India—(a) village or agricultural, and (b) prairie or nomadic. The latter consists of large herds fed on fertile non-cultivated lands, the former small herds or solitary animals reared at the homesteads, thus mostly on cultivated lands. It is generally said, moreover, that the advances of cultivation are rapidly curtailing the areas of nomadic production and thereby cutting off the sources of supply of

superior breeds. Hay-making is not practised by the Indian cultivators, and the surplus of naturally produced grass is thus left to waste. Moreover, the cost and difficulty of transport preclude the equalisation of supplies, hence in seasons of drought the greatest hardships have to be endured, and the first indication of famine is the increasing death-rate of the cattle. For example, during the famine years of 1899-1900 something like 70 to 80 per cent. of the cattle perished in certain districts of Bombay, notwithstanding the large imports of fodder made by Government, for the railways were unable to cope with the burden thrown on their resources in conveying food and fodder to the famine-stricken districts.

Famine.

It has sometimes been upheld that cattle represent the *raiyats'* capital. They certainly provide the labour for ploughing and carting, as well as very largely supply the manure and fuel used by their owners. In return the animals get what they can pick up (after the crops are off the fields) and what they can discover on the waysides and waste lands. Nevertheless they often become the cultivator's greatest source of poverty and danger. They increase beyond the needs of the neighbourhood, and thus rapidly change the character of the vegetation: noxious weeds survive and nutritious plants are gradually exterminated. Thus are the village cattle themselves not only depraved and starved, but the natural fertility and humidity of the soil lowered to such an extent that any untoward climatic disturbance only too frequently means famine. Of few localities can it be said that special food or fodder is grown for the cattle, but where this is done, as, for example, the cultivation of the cluster-bean, *Cyamopsis psoralioides* (p. 449), and of fodder crops of *Sorghum vulgare* (of which the races known as *sundhia*, *dudhia*, *nilva*, etc., may be mentioned, p. 1039) in Gujarat and Jhang, etc., etc., the superiority of the cattle in these regions has been frequently attributed to that circumstance. It is of course customary to give rich foods (including several kinds of oil-cake) to milch-cows and to bullocks in daily work. Mollison reviews the opinions that prevail in India regarding linseed, *til*, *niger*, safflower, ground-nut, cocoanut, and cotton-seed cake. [Cf. Leather, *Agri. Ledg.*, 1897, No. 8.] It is somewhat remarkable, but true, that a very large percentage of the draught bullocks of India are fed exclusively on dry food. It is of course very generally believed that green food is not suited to working cattle. This is, however, a very different question from that of the conditions of life and the food-stuffs essential to systematic breeding, where the improvement of stock is a distinct feature. The contrast between the bullocks belonging to the European planters in Tirhut and those of the Bihar peasants, or between the bullocks owned by the Burmans and those possessed by the Hindustani residents in Burma, abundantly exemplify the difference between carefully reared and properly tended cattle and those brought up under a system of indifference and neglect.

Dry Food.

In the *Dictionary* will be found a complete enumeration of the trees, shrubs, herbs and grasses known to be of value as cattle food and fodder. Excellent pasturage exists in most provinces, especially on the lower hills and great Himalayan range. Open stretches of grass-land (*maidans*) often extend from the upper limits of the forests towards the snow-line. On these uplands vast herds of sheep and goats are to be found, the latter affording the much prized *pashm* wool (hair). But on the lower Himalaya the cattle are largely fed on the leaves of four species of oak and a few other trees. The grass that exists abundantly in these tracts is as a rule

Upland Gr .

Classification of
Fodd .

cut and dried as hay in order to be exported to the plains. The extent to which leaves are utilised as cattle fodder is a speciality of India.

Rice Straw.

In the deltaic tracts and rice lands generally, the cattle are miserably poor. Grazing lands are limited, or totally wanting, and the only fodder available in any quantity is rice straw, which provides scant nourishment. Moreover, it may be said that little or no concentrated food is given even to the work cattle in busy seasons. In peninsular India, good grass is not found where the average annual rainfall much exceeds 40 inches. In some parts of that vast area, therefore, the cattle are extensively fed by hand on the produce of arable tracts (*Imp. Gaz.*, iii., 86). The grazing lands of India and the grazing rights of the people are highly controversial questions. Voelcker (*Improv. Ind. Agri.*, 169-97) discusses these very freely, and his views have on the whole been upheld by subsequent experience. But the almost complete absence of special fields of cattle food is perhaps the aspect of Indian farming that strikes the visitor as most significant. The possession of immense herds, reared on waste lands, accounts very largely for the *ghi*, which is so much traded in all over India; but one of the surest signs of the devastation caused through failure of the rains is the sudden rise in the exports from India of cheap hides—a melancholy consequence of the starvation of these unprovided-for herds.

Absence of
Cattle Food.

[*Cf. Benson, Ind. Fodder Grasses*, in *Agri. Ledg.*, 1892, No. 1; Watt, *Ground-nut as Cattle Food and Fodder*, 1893, No. 15, 87 et seq.; Leather, *Silage-making in India*, l.c., 1894, No. 2; *Feeding Exper.*, New York *Agri. Exper. Station Bull.*, 1897, No. 141; Wood, in *Journ. Board Agri.*, 1899, vi., 311-32; Walker, *Measurement of Cattle*, *Agri Ledg.*, 1899, No. 8; Leather, *Food-Grains and Fodders of India*, l.c., 1901, No. 10; Mollison, *Textbook Ind. Repts.*, especially those of Burma, deal fully with the fodder supplies and grazing rights.]

Diseases
of Cattle.

DISEASES OF CATTLE.—The *Agricultural Ledgers* enumerated below contain many valuable papers on the diseases of cattle. The more serious and special diseases are briefly:—

Rinderpest.

Anthrax.

Foot and Mouth.

Pleuro-
pneumonia.

1. **Rinderpest**—the *bossonto*, *guté*, *kalawah*, *pitchinow*, *peya*, *kyauk-pauk*, etc. 2. **Anthrax**—the *golafula*, *gutherevan*, *goli*, *suth*, *odro*, *thalorinova*, *daungthan*, etc. 3. **Foot and Mouth Disease**—the *khurat*, *aosha*, *khurpakka*, *mohona*, *mupaung*, *sha-na-kwalna*, etc. And 4. **Pleuro-pneu onia**—the *phipri*, *asok-yaw-ga*, etc. In a special Veterinary Series of *The Agricultural Ledger* have been published numerous papers on the above and other diseases which the reader, desirous of such information, should consult. Two papers may, however, be specially indicated, namely, Dr. K. Mcleod's *Measures, Legal and Sanitary, adopted by European Countries* to oppose the introduction and spread of cattle plague (1896, No. 20), and Prof. Koch's *Method of Immunising Cattle against Rinderpest* and the Resolution of Government of India on the same, together with the Opinions of Indian Veterinary Authorities (1898, No. 5). But for practical dairying operations, particulars of all the ordinary ailments of cattle will be found in the chapter on diseases of horned cattle and their treatment given by Meagher and Vaughan, in their work on *Dairy Farming in India* (1904, 113-143, 147). These authors conclude with the following recommendations, strict attention to which they consider calculated to avert serious loss and inconvenience:—

Prevention of
Disease.

“(a) Proximity of grazing grounds to the cattle-yard, enabling the

cattle to go out and back without possible contact with outside cattle or their tracks ; (b) Complete separation between the dry stock and cattle in milk ; (c) Frequent inspection of all home cattle, and immediate isolation of animals from any disorder, however simple ; and the prompt disinfection of all ropes, standings, troughs, etc. ; (d) Perfect sanitation in and about the cattle-yard, standings, stalls, etc. ; (e) Tramway lines for the conveyance of grain, fodder, etc., to the cattle-yard and the rigid exclusion of all outside draught-cattle bringing in these supplies ; (f) The allotment to sick cattle of special attendants, who must not be permitted to approach the healthy animals, or associate with the staff working in the cattle-yard ; (g) The best and most wholesome fodder, grain, cake, etc., only fed to the cattle ; and (h) Complete segregation at as great a distance as possible from the infected enclosure ; and, as calves are the principal medium, not more than sixteen calves should be housed together."

Poisoning.—Among the important causes of cattle-death has unfortunately to be given criminal poisoning. The *chumars* are the chief criminals, and their method of accomplishing their nefarious purpose is by the use of the *sui* (see *Abrus*, p. 1).

Or 'nal
Poisoning.

[Cf. Voelcker, *Improv. Ind. Agri.*, 1893, 213-5 ; Pease, *Cattle Plague*, in *Agri. Ledg.*, 1896, No. 8 ; also Kristnasamiengar, *Cattle Disease of Mysore*, 1896, No. 28.]

II. THE GOATS AND SHEEP OF INDIA.

In addition to the oxen (discussed above) the family of the BOVIDÆ includes the goats and the sheep :—

D.E.P.,
vi., pt. ii.,
54 - 3.

THE WILD GOATS.—The following are the species recognised by zoologists :—

Goats and
heep.
Wild Goat.

Capra gaurus, *Gmelin* ; *Blanford, Fa. Br. Ind.* (Mammalia), 502-3 ; *Masson, Journ. to Kalat*, 1843, 445-6 ; the *pasang* (male), *boz* (female), *borz*, *kayik*, *thar*, *sair*, *sarah*, *chank*, etc. A wild goat found throughout Asia Minor Persia, Afghanistan, Baluchistan and Sind.

This remarkably interesting goat inhabits barren rocky hills in herds of varying numbers, but always keeps much to the cliffs and crags. Capt. Hutton, who, while Resident at Kandahar, devoted much careful study to *C. agagrus* in domestication, and cross-bred it with the common goat, arrived at an emphatic opinion, opposed to that advanced by Hodgson and others, namely, that the Persian and Afghan goats at all events were not derived from *C. agagrus*. The late Dr. Blanford, the most recent author, however, says "there can be no doubt that *C. agagrus* is one of the species, and probably the principal from which tame goats are derived." The flesh of this wild goat is highly prized. The skins are valued as water and flour bags. The horns are carried by mendicants, and trumpeting horns are made of them. The bezoar-stones are found in the stomach (see *Bezoar*, p. 131).

Origin of
Domesticated
Goat.

C. falconeri, *Hugel* ; *Blanford, l.c.* 505-8 ; *Vigne, Travels, etc.*, 1842, ii., 279 ; the *markhor* (snake-eater), *ráche* (the great horn), *tush-ra* (water goat), *rezkuh*, *rush*, *pachim*, etc.

Markhor.

A magnificent animal which inhabits the Himalayan tracts west of the Beas to Kashmir, Ladakh, Baltistan, Afghanistan, Baluchistan, etc. It frequents high ranges, especially where concealment is afforded by shrubs or broken rocks, and is then met with in large herds. There are several well-marked local varieties that differ from each other mainly in the length, shape and degree of twisting and curving of the horns. It is much sought after by sportsmen, and is said to be in appearance by far the grandest of all the wild goats. Has repeatedly been bred in confinement and crossed with the domestic goat. It is generally believed, in fact, that some of the races of domestic goats with spiral horns have descended from this species. There are two important points that should be borne in mind : the direction of the spiral of the horns is outwards, not inwards (as in most domestic goats), and the *markhor* does not possess the under-fur or *pashm* (*pam*) of the alpine domestic breeds.

Or ed with
Domestic Goat.

C. sibirica, *Meyer* ; *Blanford, l.c.* 503-5 ; the Himalayan Ibex, the *skin* or *sakin*, *dabmo* or *danmo*, *kail*, *tangrol*, *buz*, *skiu*, etc.

Himalayan
Ibex.

Ibex. This ibex may be said, so far as India is concerned, to extend from the eastern limits of the last-mentioned species east to Nepal. On the north of the Himalaya, however, it is very plentiful and passes considerably to west of its more strictly speaking Indian area, so that in Central Asia it can be spoken of as distributed from the Altai to the Himalaya. It frequents the most precipitous cliffs at elevations close to the limits of perpetual snow. Is able to withstand the extreme cold through its possessing a thick under-fur (*pashm* or *pam*). This interesting animal is, in fact, much sought after on account of its under-fur, which in Kashmir is called *asali tús*. Shawls, stockings and gloves are lined with it and the wool is also woven into the remarkably fine cloth called *túsi* or into the famous ibex shawls. Cooper speaks of two specially fine qualities of *pashm*, a white and a grey, both obtained in Tibet from a small species of wild goat called *thosh*. It is said that no wool is so rich or so soft. The hair or upper-coating, on the other hand, is made into ropes or woven into coarse cloth—*pattu*—and used for coats, tents, etc. In Ladakh large numbers of this goat are annually killed in winter, when forced to descend into the valleys. In consequence a fairly extensive supply of wild *pashm* is regularly obtainable. No one has, however, recorded the existence of the ibex in domestication, nor of its having been crossed with the tame goats. Still it is sometimes upheld that the *pashm*-yielding domestic goats of the alpine tracts must have been derived from this or some closely allied extinct species.

Domestic Goat. **REEDS OF DOMESTIC GOATS.**—Very little is known of the origin of the Indian domestic goats. As just stated, *C. ægagrus* is believed to have given an important strain to a large percentage of the breeds. *C. falconeri* is viewed as having similarly contributed in building up the peculiarities of some of the breeds with spiral horns. Fossil remains of a closely allied goat have been found in the rocks of the Siwaliks and of possibly another species in Tibet. Crosses between the wild goat of Western Sind and Quetta with the *markhor* have not only been produced but found naturally and shot by sportsmen. The powers of endurance possessed by these animals may be inferred from the circumstance that *C. ægagrus* is found near the sea-level in Sind and Baluchistan and at 13,000 feet in Persia. According to Henderson, *C. sibirica* bears so strong a resemblance to certain breeds of tame goats, met with on the alpine Himalaya and Tibet, that it may be safely assumed to have given to these their undercoat of *pashm*.

Asiatic Goats of Mixed Origin. Thus, then, the authors whose opinions are of most value admit the possibility of the Asiatic goats having been derived from more than one species, and the advisability of such a conclusion (apart from the diversified form, stature, colour, habits, etc., of the tame races) receives countenance from the admitted existence of fertile hybrids between the wild species themselves, as also between these and the domestic animals. The progression in characteristics from the typical village goat of the plains and the *dúgu* goat of the lower Himalaya to the Alpine *pashm*-yielding animal may, therefore, mark the stages of adaptation and crossing of different species, with the nearer approach in the extremes to the specific types. If there be any plausibility in this suggestion, the difficulty which the early writers foresaw in any attempt to breed the true *pashm* goat on the southern slopes of the Himalaya would at once assume a distinct position. Lawrence (*Valley of Kashmir*, 364), speaking on this subject, says, "An attempt was made to introduce the shawi-goat into Kashmir, but it failed, as the climate is not sufficiently severe to induce the undergrowth of wool which nature provides in Tarfán for the protection of goats and other animals from the keen winds of that country." It would thus seem certain that the closer the effort at improvement is kept within special areas and with existing stocks the better. To cross the *pashm* goats with the non-*pashm* breeds

of Angora blood, as has been suggested, would obviously be to court failure. It might, however, be possible to cross the alpine breeds of Sind, Baluchistan and Hazara with the Angora goat, if foreign blood be considered essential.

Angora Goat.

Many years ago the proposal was made to establish sheep and goat runs on the southern slopes of the Himalaya with a view to improve and extend the Indian supplies of wool and hair. This has never been definitely tried, though much has been written on the growing necessity for better and more certain supplies of these staples. Falconer seemed to think that the *pashm* goat might be acclimatised on the southern slopes of the Himalaya, but it must not be forgotten that the down of the ibex and of the *pashm* domesticated goat seems to be directly the result of the drier and ever so much colder nature of the northern as compared with the southern slopes. Indeed the *pashm* goat may be said to actually exist at Spiti, and according to Hodgson the *chápú* is the acclimatised form of the Tibetan *chánggrá*. If this be so, the goat, even if successfully reared on a more extended scale than at present on the southern slopes, would probably yield a far inferior *pashm* than the northern stock, if indeed it did not degenerate into a form of the *pat*-yielding (not *pashm*) goat. It may, however, be safely said that for present European commerce a *pashm* goat is not an indispensable necessity of success.

Extend
Production
of Wool.

Southern
Slopes.

Speaking of the plains, sheep and goats are most successfully reared in areas that receive a moderate rainfall. Upland well-drained soils with sparse jungle growth and a considerable variety of herbage are necessary. In peninsular India the shepherds possess large flocks, with which they wander from place to place when arable land is usually clear of crops. The sheep and goats graze during the day and are folded at night on land where it is desired to obtain the manure of their droppings. This is paid for by the cultivators whose lands are thus benefited. Goats are valued for their meat and milk, and on the Himalaya for their hair.

Plains Goats.

[*Cf. Royle, Prod. Res. Ind.*, 1840, 161-72; Wallace, *India* in 1887, 147; Voelcker, *Improv. Ind. Agri.*, 212-3; Mollison, *Textbook Ind. Agri.*, ii., 59-62; Mukerji, *Handbook Ind. Agri.*, 593-4; Watt, *Provisional List Animal Prod.*, 1902, 77; Aitken, *Sheep-Feeding, Journ. Board Agri.*, Sept. 1901, viii., 155-64.]

CHIEF BREEDS.—With the exception of Mr. B. H. Hodgson's valuable paper on the sheep and goats of the Himalaya and Tibet, and of Capt. T. Hutton's paper on the sheep and goats of Afghanistan, the subject has never been systematically treated, and little can be added to the particulars given already in the *Dictionary*. I am, therefore, unable to do more than mention by name some of the better known breeds of Indian goats:—

reeds.

1. South Indi Goat.—These are gaunt in appearance and badly proportioned, but hardy and active and can exist on almost any kind of vegetation.

South India.

2. North Indi Goat.—A much finer animal than that found in the south. The ears are large and perfectly pendent. This is possibly the *jamnapari* of Hodgson. [*Cf. Hoey, Monog. Trade and Manuf. N. Ind.*, 1880, 90, 105-6; Pim, *Monog. Woollen Fabrics U. Prov.*, 1898, 2-3; *Note on Indig. Sheep and Goats of the Pb. in Land Rec. and Agri.*, 1903.]

North India.

3. Surat and Gujarat Goats.—These are small short-legged animals that are much valued as milkers.

Gujarat.

4. Nepal G t.—The best-known breed; has long flapping ears and rounded nose.

Nepal.

5. engal Goat.—This is smaller even than the Madras animal, and is usually quite black and destitute of hor . Hodgson identifies it with the *dúgú* of the Himalaya. [*Cf. Basu, Agri. Lohardaga*, 1880, i., 92; ii., 44-5; Banerjei, *Monog. Woollen Fab. Beng.*, 1899, 1-3, 35-6.]

Bengal.

6. The ill Goats of the Deccan, Sind, Rajputana and Baluchistan.—The hair of these animals is more abundant and woolly than the plains goat, and the horns

Hill.

are often large but only exceptionally spiral. These are the hair-yielding species of India.

Syrian.

7. **Syrian Goat**.—Hybrids of this breed, commonly designated "Aden goats," are well known in India, whither they are imported by the Arab traders and passed off under the names Angora or Kashmir. They have long, flapping, pendent ears and slender limbs. Their horns are usually erect and spiral.

Himalayan Goats.

8. **Himalayan Goats**.—Hodgson's paper (*Journ. As. Soc. Beng.*, 1847, xvi., pt. 2, 1003-12), as already stated, practically gives all information regarding those known to exist. He refers them to the following special breeds:—

(a) *Chánggrá*—the common domestic goat of Tibet, which hardly deviates from the wild goat (*C. ægagrus*) except in the large and pendent ears. Hutton, on the other hand, holds that so far as the Persian and Afghan goats are concerned, they could not be regarded as derived from the wild goat just named.

(b) *Chápú* or *Chyápú*—the goat of the Sub-Himalaya (especially the Cis-Himalaya). It is much smaller than the *chánggrá* and has long hair and fine sub-fleece.

(c) *Sínal* or *Singál*—an inhabitant of the more northern parts of the Sub-Himalaya from Kumaon to Nepal, where it is probably indigenous. The surcoat and fine sub-fleece, though inferior to those of the *chánggrá* and *chyápú*, are yet capable of being applied to the manufacture of ropes, blankets, serges, etc. It is less patient of change than the *chánggrá* or *chyápú*, but the mutton is good, especially that of the kids.

(d) *Dágú*—a goat of the Central Sub-Himalaya and lower warmer tracts. It is characterised by the absence of the long hair and the nearly as frequent absence of the interdigital pits of the other breeds. The male is much larger than the female, and often almost shaggy. There is no sub-fleece, the hair is coarse and next to useless. [*Cf.* Barnes and Lyall, *Settl. Rept. Kangra*, 1889, 38-43; Diak, *Settl. Rept. Kangra*, 1898, 36-68; Drew, *Jummoo and Kashmir*, 1875, 288; Lawrence, *Valley of Kashmir*, 1895, 360-4.]

heep.

THE WILD SHEEP.—It has, however, been known from the most ancient times that wild sheep and goats exist in India. Ælian (compiling from Megasthenes, 300 B.C.) speaks of the wild sheep and goats on the mountains of India. If considerable uncertainty exists as to the origin of the Indian goats, a far greater obscurity enshrouds the sheep. The structural difference between the members of the genus *CAPRA*—the goats—and that of *Ovis*—the sheep—is very small indeed, and one species—*Ovis nahura*—is practically intermediate. The origin of the Indian tame sheep is unknown. Continuing the example above, the following are the wild species:—

Origin of Domestic Sheep.

vis hodgsoni, *Blyth* (. A on, *Hors.*); *Blanford, Fa. Br. Ind.* (Mammalia), 494-5; the Great Sheep of Tibet, the *nyan*, *nyand*, *hyan*, *niar*, etc. This magnificent sheep, probably the largest of the genus, does not usually occur on the Indian side of the Himalaya. It is the shyest and wildest of all animals, and is very hard to kill. It has never been domesticated, but wild hybrids between it and *O. vignei* have been shot.

Great Sheep of Tibet.

Bharal.

. nahura, *Gray*; *Blanford, l.c.* 499-501; the Bharal or Blue Wild Sheep, the *bharal*, *bharut*, *na*, *wa*, *nervati*, *nao*, etc. This sheep is met with in the alpine tracts (between the limits of forest and snow) from Bhutan to Ladakh and Western Tibet.

Great Sheep of Pamirs.

. poli, *Blyth*; *Blanford, l.c.* 496-7; the Great Sheep of the Pamirs: *M. co* Polo's sheep: is the *kuchkár*, *ras*, *rush*, *kulja*, *arkar*, etc. This remarkable sheep only comes within the Indian area at Hunza, north of Gilgit. [*Cf.* Marco Polo, *Travels* (Yule, transl.), i., 163-9.]

Ural.

. vi ei, *Blyth*; *Blanford, l.c.* 497-9; the Ural or Sha—the Bearded Sheep, known to the Natives as the *kuch*, *koch*, *guch*, *gad*, *mish*, *sha*, *ural*, *uriar*, etc. It is the wild sheep of the Salt Range in the Panjáb and of the Suliman Range of Hazara and Afghanistan, etc. The varieties most generally recognised are the *ural*, which occurs between 800 and 5,000 feet, and that called the *sha* at much higher altitudes—10,000 to 14,000 feet.

Hybrids.

It has been bred freely with tame sheep, and wild hybrids (as already noted) between it and *O. hodgsoni* have been shot. If, therefore, any of the preceding

animals have contributed to the breeds of Indian sheep, *O. vignei* seems to have done so. It apparently affords a small proportion of the *pashm* known as *thosh*, and from the lachrymal sinus a thick gummy substance is obtained that is much valued in greasing metal locks. Mr. Drummond informs me that pure or half-breed *dumbas* have been crossed with this wild sheep and that the progeny exhibit, while young, an under-fleece similar to *pashm*. But according to local belief this cross is only attained if *dumba* stock be employed.

Breeds of Domestic Sheep.—Sheep are met with throughout the plains and lower hills of India and up the Himalaya to the sub-arctic zones. The breeds of Indian sheep are quite as extensive and diversified as those of Europe. Some are tropical, thriving in swampy regions or on dry, arid tracts, others warm temperate, still others temperate or even arctic. There has, however, been even less of an authoritative character written of the Indian sheep than of the goats. Most writers have discussed the Patna, Dumba, Meywar, Madras, Mysore, etc., breeds without having considered it necessary to detail their characteristic features. Shortt (*Manual of Indian Cattle and Sheep*), if his illustrations can be viewed seriously, would seem to establish for South India certain well-marked breeds, and doubtless extensive diversities exist among the sheep of other provinces. But, speaking generally, it may be said of perhaps more than half the breeds found on the plains of India, that they afford a kind of hair rather than a wool. They are reared chiefly on account of mutton, their fleece, like the hair of the village goat, being, comparatively speaking, valueless.

But although many of the sheep of India yield a fleece of hair rather than of wool, certain breeds give fairly good wool. Of this class may be mentioned the black-headed sheep of Coimbatore, the woolly sheep of Mysore, the sheep of large portions of the Deccan, of Rajputana, of the Panjáb, and, in Bengal and the United Provinces, the so-called Patna sheep. Although there are possibly several very distinct breeds of large fat-tailed sheep (all designated *dumba*), these should be classed as wool-yielding breeds. They have been crossed with the Patna, the Merino and other imported sheep, and apparently with satisfactory results, though the improvement effected cannot be said to have been lasting. Some of the fine wools imported from Afghanistan and Persia are obtained from breeds of *dumba* sheep, and this fact having been ascertained many years ago, effort was put forth to secure stock for breeding purposes. So far the result, however, has been unsatisfactory, for when conveyed to the moister tracts of India, the fat tail has proved a source of danger. It is liable to disease, so that unless a breed could be produced, in the natural habitat of this animal, that would preserve its merit as a wool-producer during successive crosses in which it was gradually developed into a condition suitable to the plains of India generally, it is not likely to be of much value to future breeders. It may, in fact, be said in conclusion that, so far as past experience goes, the breeds of most value, as Indian stock for improvement, are the Coimbatore, Mysore, Rajputana and Patna. But it may be added that perhaps the majority of persons who have given this subject anything like careful consideration seem to incline to the view that except in certain tracts, there is very little hope of India as a whole becoming of much greater moment than at present as a country of wool-supply. Interest is far more keenly directed towards facilitating importation from the mountainous countries bordering on India, than in any material improvement of the wools of the

Domestic Sheep.

Fat Tail.

Chief Wool-
bearing Sheep.

plains. [*Cf. Orrah, Wool of Baluch. and the Introd. of Merino Sheep and Angora Goats, March 1890.*]

The following may be mentioned as the better known breeds of sheep in India:—

Chief
breeds.

Rajputana.
Tuttyghar.

1. Rajputana (eywar) Sheep.—These are the finest and largest sheep in India. They are sometimes called Delhi-Hansi or Tuttyghar sheep. They have poor wool, but the mutton is large though somewhat coarse. [*Cf. Ann. Rept. Civil Vet. Dept., 1893-4, 14-6.*]

Patna.

2. Bengal and Patna Sheep.—The former is very inferior but the latter one of the best breeds in India. They yield good wool and fatten readily. In 1836 an effort was made to improve the Patna sheep by crossing them with Southdown rams. So also a similar effort was made with Bhagalpur sheep.

Madras.

3. Madras Sheep.—The best are those of Chingleput, Kistna, Godavari, Ganjam, Arcot, Salem, Trichinopoly, Tanjore, Madura and Tinnevely. They are coated with a coarse brown wool or hair of little value. An experiment was for some years prosecuted at Heraganhalli to improve these sheep by crossing them with Merino rams imported from Australia. This was abandoned in 1863.

Nellore.

4. Nellore Sheep.—A large breed, examples of which have been known to scale 80 to 100 lb. They are tall, leggy, and white or light brown in colour.

Coimbatore.

5. Coimbatore Sheep.—This is known as the *kurumba* breed. It is a wool-producing animal, small in size, the prevailing colours being black with white heads. They fatten well, and the mutton of gram-fed animals is rich and well-tasted.

Mysore.

6. Mysore.—This is a woolly breed. The prevailing colour is light to a very dark grey or black. It furnishes the best fighting rams of the plains. [*Cf. Buchanan-Hamilton, Journ. Mysore, etc., 1807, i., 119-21; ii., 276-8; iii., 354-5.*]

Bombay.

Breeding
Experiments.

7. Bombay Sheep.—Dr. Hove, in 1787, speaks of the sheep in the Deccan as being the finest he had seen in India and as having superior wool. So long ago as 1835 Col. Jervis conducted extensive experiments with a view to improving the Bombay sheep. Subsequently Col. Pottinger, Sir A. Burnes and others brought sheep from Kabul, the districts of the Upper Indus, Persia, the Cape of Good Hope and England. A farm was established at Ahmednagar, and for some years vigorous experiments at stock improvement were prosecuted. This was reported on by Sir George Arthur in 1843, who recommended that fresh Merino rams should be continuously imported for some years to come. The subject seems, however, to have been suddenly forgotten and the farm abandoned, for nothing of any importance was subsequently published regarding it. Mollison (*Textbook Ind. Agri., ii., 59*) says nothing of these experiments nor of the fate of the farm. He offers, however, many useful and practical suggestions based chiefly on experience gained in Bombay. Sheep and goats, he says, are most successfully bred in districts with moderate or light rainfall and light, naturally well-drained soils. Neither sheep nor goats thrive during the monsoon in heavy-soil districts. In the breeding districts large flocks do not thrive unless they are continuously grazed on clean ground. Large flocks of sheep and goats are brought in the fair season by professional shepherds from Kathiawar into the plains of Northern Gujarat, and also from the upland comparatively dry waste grazing lands east and north of Khandesh, to the black-soil tracts and arable plains of the Deccan. A few goats among the sheep are decidedly advantageous. They lead the flock and keep the sheep moving and thus grazing. [*Cf. Morgan, Sheep-Breeding in the Deccan, in Agri. Ledg., 1895, No. 18.*]

Light Rainfall
and Light Soils
Essential.

Nepal.

8. Nepal Sheep.—Of these there are two kinds—the village *ghorpalla* and the forest *ran baria*. The last is a small and almost semi-wild animal that lives in large flocks on the wooded hill slopes.

Kashmir.

9. Kashmir Sheep.—Lawrence (*Valley of Kashmir, 360-4*) gives many interesting particulars regarding the sheep and wool of Kashmir, but says nothing of the breeds met with except that some are as good as the Southdowns. Mr. Drummond informs me that in Kashmir it is the custom to wash the sheep in the river before being shorn, a circumstance that would point to the wool being valued more highly than is commonly believed. Baldrey (*Agri. Journ. Ind., 1906, i., pt. iii., 201-4*) urges the "Benefits of Sheep-dipping" in India.

Himalayan and
Tibetan.

10. Himalayan and Tibetan Sheep.—Hodgson mentions some five breeds with, under some of these, several sub-breeds. Space cannot be afforded to do much more than enumerate the principal examples of these by name:—

Hünia.

(a) *Hünia* of Western and *Háluk* of Eastern Tibet. A tall, graceful animal,

the universal beast of burden on the higher snowy ranges—is docile and sure-footed. Hodgson compares this with the great wild sheep (*O. hodgsoni*). It cannot endure the rank pasture or high temperature of the Sub-Himalaya. Mutton and fleece are both excellent.

(b) *Silingia* or *Siling* sheep or *Peluk* of the Eastern Himalaya. According to Hodgson, the Siling country corresponds to the *Serica* regio of the classics. The animal is smaller than the *huniá*. In colour it is white tinged with fawn.

(c) *Báruál* or *Baruál* is a Cis-Himalayan breed and the ordinary sheep of the Cachar or northern regions of the Sub-Himalaya between the Júmá and the Kirant. Hodgson, in fact, says this breed practically extends from Kumaon to Sikkim. It is the great fighting ram of the hill tribes. It is remarkable for its massive horns entirely covering the top of the head. The flesh and the fleece are both abundant but coarse. By far the largest number of the *ráhris* or coarse blankets and serges manufactured in these hills, and which are extensively exported therefrom, are made of *báruál* wool. Coarse as this wool is, it is, however, superior to the wool of the plains.

(d) *Cágéa*—This is the characteristic breed of the central region of the Sub-Himalaya. It is reared rather by householders than shepherds, and for its flesh rather than its wool. It is a handsome animal, but its head is too large, though the legs are short.

(e) The *Teraí* Sheep. This is practically identical with the sheep of the plains.

It may in conclusion be pointed out that Hodgson's Trans-Himalayan sheep (the *huniá* and the *silingia*) are, like his Trans-Himalayan goats (*chángá* and *chápú*), far superior to his Cis-Himalayan breeds. If, therefore, India cannot acclimatise and develop new breeds on the southern slopes of the Himalaya, attention should be given to increased facilities of transport and more friendly intercour with the Trans-frontier tribes for increased supplies of superior wool.

11. *ira* and *D ba* Sheep.—Some at least of the breed are natives of Afghanistan and Persia, and others of Africa. They are frequently imported into India, and are large sheep characterised by the immense development of masses of fat placed on either side of the tail, forming stores of nourishment which are drawn upon during the winter months, when fodder is scanty. Hutton tells us that in some parts of the country the tail grows, in fact, to such a size that a small wheeled carriage has often to be constructed to carry its weight. Hodgson calls them *púchia* (tailed) sheep. The wool is of good quality, and on that account they have often been crossed with Indian plains sheep. Mollison says *dumba* sheep have proved exceptionally suitable for crossing with the Deccani stock. The wool of these half-breeds, like that of the pure *dumba*, is of fine quality and long. The mutton is said to be coarse, though the tail is sometimes spoken of as of great value.

Ælian (*De Nat. Hist. Anim.*, 250 A.D., iv., 32) speaks of the tails of the Indian sheep reaching to their feet and as being cut open by the shepherds, the tallow removed, and the tails sewn up again. Marco Polo, in the 13th century, and Varthéma, in the 16th, describe the *dumba* or Ethiopian sheep as seen by them on the east coast of Africa. Marco Polo says the tail often weighs 30 lb., but Varthéma puts it at a lower figure, 15 to 16 lb. Terry (*Voy. E. Ind.*, 1622 (ed. 1777), 90) observes that "their sheep differ from ours by their great fleshy bob-tails which severed from their bodies are very ponderous. Their wool is generally coarse but their flesh is not so." There would thus seem no doubt that this particular sheep has existed in India from fairly remote times. The head and neck are quite black and the body otherwise white. In the Cairo Museum, among the ornaments found in the mummy-pits, there is a little figure of one of these sheep, so that it may safely be said they have been known from ancient times and beyond the limits of India. [Cf. Cordemoy, *Le Prod. Colon. d'Origine Animale*, Paris, 1903, 126–38.]

III. HORSES, ASSES, AND MULES OF INDIA.

The horse has been a domesticated animal since prehistoric times. Ælian, compiling doubtless from Megasthenes, 300 B.C. (*De Nat. Hist. Anim.*, xvi., 2–22), says, "In India there are herds of wild horses and also of wild asses." No aboriginal or truly wild horse is known to exist to-day, though wild representatives of the ass are well known. [Cf. Blanford, *Fa. Br. Ind.* (Mammalia), 470–1.] There seems, however, little doubt that

Horses,
Asses, etc.

all the existing races and breeds of horses have descended from one common stock, which Darwin believed was dun-coloured and more or less striped. In Neolithic times a wild horse would appear to have existed in Europe, but the animals of the present time have probably not been developed from these, but from animals which it is well known were imported from Asia into Greece and Italy. But even these Asiatic ancestors were doubtless only a consequence of a still earlier long-continued selection from a stock or stocks that to some extent may be indicated by the fossil remains discovered. The artificial selection conducted by man has been toward specific purposes. The English thoroughbred may be mentioned as the final manifestation in speed; the English draught-horse in working capacity; and the Shetland pony in sure-footedness and suitability for mountainous regions. What may be true of England can be shown as equally applicable to all countries wherever the horse has been appreciated in agricultural, industrial and political life. The most ancient histories and traditions of India point to a specialisation in warfare. *Ælian* describes the King's stables; the use of the bit and bridle in making the horses move at a measured pace; the breaking in of the animals by forcing them to gallop round and round in a ring; and when on the march, we are told the war chariots were drawn by oxen and the horses led on a halter so that their legs might not be galled nor their spirits damped by drawing the chariot to the battle-field. None of the early writers would seem to make even the most distant allusion to the Indian horse being used for agricultural purposes or for transport; adaptation, therefore, to riding and swiftness were the directions of early Hindu influence on the horse. The establishment of the rule of peace under British supremacy of necessity meant the overthrow of martial power and the loss of the races of fiery chargers that doubtless previously existed in India.

Special Selection.

Bit and Bridle.

Early Hindu Influence.

Indian Breeds.

Direct Adaptation.

Improvement Assured.

Kathiawar.

Principal Indian Breeds.—There seems at all events little doubt that the Native breeds of horses have diminished and deteriorated since the establishment of British rule in India. The suppression of the predatory system lessened the demand, and the superior Lakhi and Cutch breeds which for centuries had been famous became almost, if not altogether, extinct. It is probable also that the requirements of modern warfare for larger and more powerful animals than India naturally produced, led to a system of artificial breeding, in which size was the object mainly aimed at, an object that might easily have resulted in the deterioration of the original small, hardy and swift breeds and the production of badly formed and weedy animals. Within recent years the Government of India have adopted, in the Civil Veterinary Department, a policy of supplying specially selected stallions to each important centre. These have been chosen in consideration of the most hopeful directions of improvement of existing stock, and their services are placed at the disposal of horse-breeders free of charge, provided the mares have been examined, approved and branded, by a representative of the Department. According to universal repute this has had a most beneficial effect. The following are some of the better known indigenous breeds:—

1. **athiauw and Rajputana.**—The Chiefs in these States still continue to give attention to horse-breeding and many of them keep up very large stables, in which the most careful selection is observed. The original breed—known as the Kathi—was noted for its great powers of endurance. The peculiarities of the animal are that it is generally under-sized and small-boned and has a distinctive mark, a black cross down the back and black bars on the legs, the colour of the

coat varying in every shade of dun. It is supposed to possess a strong strain of Arab blood, an opinion supported by the known frequent intercourse between the two countries. The mares are most esteemed, as the horses are noted screamers. The Bhavnagar and Palitana Princes take the greatest possible interest in the preservation and improvement of this peculiar and special breed.

2. **Bombay.**—The horses of Kach and Sind do not materially differ from those of Kathiawar. They are usually a little over fourteen hands, are well made, spirited, showy in action, with clean limbs, good bone, thin long neck, large head, outstanding ram-like brow, and small ears. Their great defect is their bad temper. But there may be said to be three other types in the Presidency in the hardy Maratha pony, the little Gujarati, and the Bimthadi of the Deccan. The last mentioned is one of the best breeds in India.

3. **Waziri and Baluchi.**—A fine breed of hardy and active animals. They have good shoulders, very deep and moderately broad chests and angular drooping quarters, very broad across the hips. They make excellent troopers on account of their speed and endurance, and, crossed with Arabs and thoroughbred English horses, become good cavalry remounts.

4. **Panjab.**—There are many special races, such as those reared about Rawalpindi, Jhelam, Gujrat, Gugaira and Lahore. In the Sikh times the greatest care was bestowed on them, and stallions from Kathiawar, Kach, Baluchistan and Afghanistan were regularly imported and used to improve the stock. The average Panjabi country-bred to-day is small, but possesses great powers of endurance. It used to be a by no means uncommon occurrence to hear of an *ekka* pony dragging a cart and three passengers from Simla to Kalka, thus covering 58 miles in one day, without, as the saying goes, "turning a hair." This is representative of the hardy little animals found on the plains adjoining the North-West Himalaya. In former times the Sikh cavalry were horsed from Dhanni, north of the Salt Range, and even now large numbers of remounts are drawn from that country.

5. **Burma and anipur.**—The ponies of Burma, which are small, hardy and exceedingly tractable, are said to be all importations from the Shan States and Manipur. Their characteristic pace is an unbroken run, in which the shoulders seem to roll from side to side. The pure Manipur is generally considered the best of all Indian ponies. It is well under thirteen hands, is mostly dun-coloured, and is possessed of wonderful powers of endurance and weight-carrying capabilities.

6. **alayan Ponies.**—The *Ghunt* or *Khund* breed is met with in Lahoul and Spiti, and is employed almost entirely for saddle purposes. It is never over twelve hands, is strongly built, exceptionally surefooted and hardy, but is often very hard-mouthed and stubborn. A similar animal is the Bhutia pony, which often attains a height of fourteen hands. A larger and more valuable breed is that known as the Yarkand pony. It much resembles the *Yabu* of Afghanistan; has a short round body, deep chest, full quarters, and thick limbs—a miniature English cart-horse. It is an admirable pack-horse, and inured to heavy loads. It moves at about five miles an hour, and if allowed to preserve that pace has great powers of endurance. Closely allied is the pack and riding pony of Balistan and Kashmir.

7. **Asses and mules.**—The ass exists in all parts of India and is largely used as a beast of burden, especially by the *dhobis* or washermen, potters, tinkers, etc. As a rule it is badly cared for, its only redeeming feature being its cheapness. In Kathiawar there is a specially good breed of donkeys, of which the Halar or Jhalavad white variety is specially deserving of notice. The people of the interior Himalaya have also a peculiar breed—a very small black animal with long shaggy hair. This they bring with them when they come down in the winter months to seek work at Simla and other outer hill stations. Mules seem to have been known from the most ancient times in India. Elian says that the mares are often covered by the wild asses, red-coloured mules being the result. These are very fleet and impatient of the yoke. They are caught with foot-traps, and when only two years old may be tamed and domesticated. They are then taken to the King of Persia. Blanford gives full particulars of the Asiatic Wild Ass. It is found throughout Central and Western Asia, a few being occasionally seen in Baluchistan, the Panjab frontier, and even east of the Indus in Bikanir and the Rann of Kach.

For many years past the Government of India have made strenuous efforts to improve the breed of the plains donkeys, and to secure the rearing of a good quality of mules. They have accordingly supplied donkey stallions and offered

rewards and prizes for good mules. The Natives of India have, in many localities, a semi-religious objection to breeding mules. [Cf. *Ain-i-Akbari*, 1590 (Blochmann, transl.), 132, 152; Linschoten, *Voy. E. Ind.*, 1598, i., 54; Terry, *Voy. E. Ind.*, 1622 (ed. 1777), 132-4; Barbosa, *Coasts E. Africa and Malabar* (ed. Hakl. IV. THE DOMESTICATED PIGS AND WILD BOARS OF INDIA.

Pig or Hog is the name applied to different animals of the family SUIDÆ, the only representative in India of the sub-division of the Ungulates known as *Suina*. Blanford enumerates the following species :—

D. P.,
iv., 53-4.
Pigs.

Indian
Pigs.

S. cristatus, Wagner; Blanford, *Fa. Br. Ind.* (Mammalia), 560-2; INDIAN WILD BOAR, *sur, bad jamwar, varaha, paddi, dukkar, pandi handi, tan-wet*, etc. This is the only species of any interest or importance economically. It is found throughout India, from the sea-level to an altitude of about 12,000 feet, wherever there is sufficient shelter, either of long grass, low jungle or forest. When abundant it does great damage to crops. The tame pig of India is probably derived from the wild animal, and in some places is said to breed with the latter. Several races of domesticated pigs are met with in India, where religious and caste beliefs allow of their being kept. In the article on Lard (pp. 701-2) it will be seen that two chief classes of pigs are spoken of, namely the "China pig" and "the Country pig."

"China Pig."
"Country Pig."

S. anda anensis, Blyth; Blanford, *l.c.* 562-3. The Andaman Pig. A small animal, some 20 inches high, occurring in the forests of the Andaman Islands.

S. salvani, Hodgs.; Blanford, *l.c.* 563. The Pigmy Hog. In the forests at the base of the Himalaya in Nepal, Sikkim and Bhutan. Its habits are very similar to those of *S. cristatus*. It is found chiefly in high jungle grass, in herds of five to twenty. They are rarely seen, as they leave the forests at night only, but may be traced to their lairs by the mud coatings of the lower vegetation left behind them. In Manipur I found this species to form coverings over their lairs by breaking and throwing down the spiny bamboo.

Pig-skin.

The pig affords various economic products, the chief of which are Bristles, Lard, Meat (Pork, Ham, etc.) and Skin. LARD is separately dealt with under that heading (pp. 701-3). PIG-SKIN forms, when tanned, a leather which is principally valued for saddlery. That of the wild boar is much thicker than that of the domesticated animal, and consequently offers more difficulty in the process of tanning and preparation. It is also used in the manufacture of many small articles of leather-ware, such as purses, coverings of pocket-books, etc.

Bristles.

Bristles are employed chiefly in the manufacture of brushes, and the export trade in bristles and other brush fibres in recent years is very considerable. For the period 1900-7, the following were the EXPORTS of bristles and fibres for broom and brush manufacture :—1900-1, 49,682 cwt., valued at Rs. 14,93,685; 1901-2, 48,488 cwt., Rs. 13,65,600; 1902-3, 70,917 cwt., Rs. 15,79,002; 1903-4, 83,258 cwt., Rs. 20,76,331; 1904-5, 81,290 cwt., Rs. 18,39,854; 1905-6, 93,873 cwt., Rs. 21,51,028; 1906-7, 88,158 cwt., Rs. 17,68,930. Of the total for 1905-6, Madras exported 89,978 cwt. and Bengal 3,604 cwt., and the countries to which the largest quantities went were—the United Kingdom, 30,485 cwt.; Germany, 27,874 cwt.; Belgium, 24,463 cwt.; Ceylon, 5,536 cwt. The IMPORTS are compara-

Exports.

Imports.

tively insignificant, averaging for 1900-7 about 450 cwt. In 1904-5 they reached 1,099 cwt., valued at Rs. 29,856; in 1905-6, 697 cwt., Rs. 17,462; and in 1906-7, 599 cwt., Rs. 25,219. Mostly from the United Kingdom and Germany.

Of *Bacon* and *Ham* India annually imports large quantities, and the exports are small. The IMPORTS for 1900-7 were as follows:—1900-1, 1,144,716 lb., valued at Rs. 7,61,782; 1901-2, 1,136,959 lb., Rs. 7,47,093; 1902-3, 1,231,934 lb., Rs. 8,16,613; 1903-4, 1,267,724 lb., Rs. 8,16,223; 1904-5, 1,373,474 lb., Rs. 8,09,678; 1905-6, 1,600,898 lb., Rs. 9,40,140; 1906-7, 1,487,729 lb., Rs. 9,52,715. Almost the whole comes from the United Kingdom, viz. 1,575,838 lb. in 1905-6, while small quantities are drawn from Hongkong, Australia, the Straits Settlements, Germany, and Sweden. The EXPORTS of Indian hams amounted in 1904-5 to 672 lb., valued at Rs. 150, and in 1906-7 to 259 lb., valued at Rs. 150. The re-exports in 1904-5 were 7,323 lb., valued at Rs. 4,358, but in 1906-7 only 537 lb. Thus, adding together all the available returns of the products derived from the pig, the exports in 1905-6 were Rs. 21,69,778 and the imports Rs. 10,17,138; and in 1906-7, exports Rs. 17,84,827 and imports Rs. 10,70,304. The decline in the exports of lard and increase in the imports point to a serious defect, and the large demand for foreign ham and bacon is significant. There are thus great possibilities in the future.

Bacon
and Ham.

Total Trade.

TRADE IN INDIAN LIVE STOCK.

Trade.

Of the estimated number of animals of all sorts (220 million in 1904-5), about 23 per cent. are annually exported in the form of hides and skins.

But India imports and exports live stock, and by sea as well as across her land frontiers. Hence the returns under these headings have to be taken into account. It may be desirable to set forth the Trans-frontier trade before exhibiting the foreign. In the official statistics the imports are referred to the following groups—(a) Horses, Ponies, Mules: (b) Cattle: (c) Sheep and Goats: and (d) Other Kinds. The totals for the year 1904-5 were 665,024 animals, valued at Rs. 74,74,928; for 1905-6, 685,732 animals, Rs. 65,30,041; for 1906-7, 714,368 animals, Rs. 70,12,607. The most important are the cattle, 105,726, valued at Rs. 44,04,266 in 1906-7: the sheep and goats, 166,653, valued at Rs. 6,12,062: and other kinds of animals 434,704, valued at Rs. 13,14,543. The chief countries of supply of cattle are Nepal, North Siam, and the Southern Shan States. For sheep and goats, Northern and Eastern Afghanistan, Nepal and Kashmir. Of the other kinds, Nepal, South Siam and North Siam. The Trans-frontier exports from British India are less important and need hardly be reviewed. The totals in 1906-7 were 92,644 animals, valued at Rs. 11,78,866. Perhaps the most remarkable feature of the trade recorded as carried by rail and river is the fact that Bengal is the chief exporting province and the United Provinces the principal importing area. The next most important receiving centres are Calcutta and Bombay.

Trans-
frontier
Traffic.

Imports, Cattle.

Sheep and Goats.

Exports.

Turning now to the transactions by sea, the IMPORTS are most valuable under the heading of horses. The total imports in 1903-4 were valued at Rs. 53,62,833, of which Rs. 52,48,590 represented the horses brought mostly from Australia into Bombay and Calcutta; in 1904-5, Rs. 59,27,625 (horses, Rs. 55,47,939); in 1905-6, Rs. 49,41,452 (horses, Rs. 46,76,055); in 1906-7, Rs. 46,55,792 (horses, Rs. 44,88,933). Of the EXPORTS it may be said the position is reversed, the traffic in horses being the least important. The total for 1903-4 was returned at

Imports of
Horses.

Rs. 22,27,523, of which Rs. 21,23,214 represented cattle, sheep and goats, etc.; 1904-5, Rs. 19,40,129 (Rs. 18,98,380 cattle, sheep, etc.); 1905-6, Rs. 19,33,828 (Rs. 19,07,228 cattle, sheep, etc.); and 1906-7, Rs. 22,63,176 (Rs. 22,21,416 cattle, sheep, etc. The horses go mainly from Bengal and Bombay to Ceylon and Mauritius, and of the others Madras practically conducts the entire trade, sending the animals to Ceylon and the Straits Settlements.

Fodder.

CATTLE FOOD AND FODDER.—Exports.—It is somewhat surprising to discover in the published returns of the foreign trade of India, a heading “Fodder, Bran, and Cattle Food, including Hay and Straw.” This is referred to three groups, as follows—Oil-cake: Rice bran: Other sorts. The total exports under these three headings were in 1900-1 valued at Rs. 70,13,826; in 1902-3, Rs. 85,73,627; in 1904-5, Rs. 97,21,116; in 1905-6, Rs. 1,18,15,434; and in 1906-7 at Rs. 93,99,644 (£626,642). Of the large amount for 1905-6, Rs. 51,99,194 represented the value of oil-cake, and Rs. 55,41,825 that of rice bran. Practically the whole of the RICE BRAN goes from Burma and the OIL-CAKE very largely from Madras, with a fair amount from Calcutta and the balance, very nearly, from Bombay. Fully a third of these articles of cattle food is consigned to the United Kingdom; another third to Ceylon, the Straits Settlements and Germany in approximately equal quantities. The balance goes to Java, the Philippines and East Africa, followed by France, Aden, Hongkong, Belgium, etc.

Exports.

Rice Bran.

Beef and
Mutton.

Prices of Beef and Mutton.—Particulars are given in *Prices and Wages in India* (1904) of beef and mutton in certain localities of Western India since 1855. During that time they have practically remained stationary: if anything, cheapened. Taking the average of the quinquennial period 1871-5 as a standard, the price in the Presidency for BEEF was 25 rupee a seer (= 2 lb.); in Sind 17; in Rajputana and Central India 16. For MUTTON, Bombay 31; Sind 18; Central India and Rajputana 21. Taking these as 100, BEEF in Bombay was (in 1903) 80; in Sind 118, and in Central India and Rajputana 50; MUTTON similarly was 100 (during 1871-5) in Bombay, and in 1903 it was 97; in Sind 144, and in Central India and Rajputana 95. These results are doubtless fairly expressive of India as a whole; but no other returns are available, so that particulars of the other provinces cannot be furnished.

For trade in Lard and Tallow, see the separate article (pp. 701-3); Hides and Skins (pp. 632-40); and Oils (pp. 813-4, 819).

THE KAMELA PLANT

MALLOTU
PHILIPPI N I

pikunkai, etc. A little branched climber, met with in North-West India, Sikkim, Assam and Eastern Bengal.

Is cultivated in most parts of India for its fruit. Rich soil should be selected, and the seed sown from March to June in lines 5 feet apart. When the young plants are about 4 inches high, supports are required. Until the rains begin, the first sowings have to be regularly watered. The fruit is highly esteemed by Natives and eaten either in curries or dressed with clarified butter. When fully developed it is about a foot long, but if allowed to grow longer than 4 inches it rapidly deteriorates. The seeds possess emetic and purgative properties and also yield an oil. The fibrous texture of the fruit forms, like that of *L. egyptiaca*, a cheap and efficient flesh-brush. [Cf. Gollan, *Ind. Veg. Gard.*, 1892, 117-8; Banerjee, *Agri. Cuttack*, 1893, 117-8; Woodrow, *Gard. in Ind.*, 1899, 333-4; Firminger, *Man. Gard. Ind.* (ed. Cameron), 1904, 168.]

Bath-sponge.

Var. a ara; *L. amara*, Roxb.; Prain, l.c.; *Rec. Bot. Surv. Ind.*, iii., 216; *karui-taroi*, *ghosha-latá*, *úta-jhinga*, *ránturai*, *kadú-sirola*, *adavi-bira*, etc. Met with all over India, especially on the western side. The fruit is largely used in Native medicine. The juice of the roasted fruit is applied to the temples to cure headache, and the ripe seeds are generally said to be a sure and safe emetic. [Cf. *Pharmacog. Ind.*, 1891, ii. 80-1.]

L. gyptiaca, Mill.; Duthie and Fuller, l.c. 61, t. lxiii; *Rec. Bot. Surv. Ind.*, iii., 60, 216. The *ghia-taroi*, *dhundul*, *bhol*, *hasada*, *dilpasand*, *ghosálé*, *gutti bira*, etc. A large climber common everywhere and often cultivated, especially in the plains. The fruit is edible, and when dried forms a structure of interlacing fibres, used as a flesh-brush in the Turkish bath or as a substitute for the bath sponge, and has more recently been made into boot-socks. The seeds are emetic and cathartic and yield an oil. [Cf. Dodge, *Useful Fibre Plants of the World*, 1897, 229; Woodrow, l.c. 333-4.]

Boot-socks.

L. echinata, Roxb.; *bindaal*, *janthori*, *kukad-vel*, etc. A small climber, native of Gujarat, Sind and Bengal (Purneah and Dacca). The fruits ripen in the cold weather and are medicinal, as is also the stem. It is a bitter tonic and powerful diuretic. [Cf. *Pharmacog. Ind.*, 1891, ii., 81-6; Sen, *Orig. Res. in Treatment of Trop. Diseases*, 1902, 95-8.]

ALAC A CAPITATA, Linn.: *Fl. Br. Ind.*, i., 329; Cooke, *Fl. Pres. Bomb.*, 1903, i., 99; Duthie, *Fl. Upper Gang. Plain*, 1903, 84; **D. P., v., 109-13.**
MALVACEÆ. *The kan (ban)-bhendi.*

An erect annual, native of West Tropical Africa and of Tropical America; introduced into India and now plentiful throughout the hotter damp tracts from the United Provinces to the Karnatak. It yields an excellent fibre, 8 to 9 feet long, which experts have decided is little if at all inferior to jute. It was at one time hoped that Bombay through the cultivation of this plant might secure a good and profitable substitute for Bengal Jute. These expectations have never been realised, but the plant in some parts of the Presidency has become so abundant as to be often viewed as indigenous. [Cf. *Offic. Correspond. on Exper. Cult. in Bomb.*, 1878-82; *Agri. Ledg.*, 1896, No. 6, 30; Dodge, *Useful Fibre Plants of the World*, 233; Woodrow, *Gard. in Ind.*, 1899, 184; *Imp. Inst. Tech. Repts.*, 1903, 69.]

Trees*, 1906, 590; **EUPHORBIACEÆ.** *The kamela*, *kamala*, *kambila*, *ruin*, *rori*, *sinduri*, *shendri*, *punag*, *tung*, *gangai*, *rolli*, *puroa*, *kapli*, *kumkuma*, *kurku*, *tawthidin*, etc. A small tree, usually with a buttressed trunk, occurring along the foot of the Himalaya from Kashmir eastwards (rising to 4,500 feet in altitude); also in Bengal, Central, Western and Southern India; Burma; the Andaman Islands and Ceylon.

D. P., v., 114- 4.
amela.

Dye.

Dye.—The most important product of this tree is the *kamela* powder—a DYE formed of the red glands found on the surface of the capsule. It is used chiefly for imparting to silk a bright orange or flame colour. A full account of the history of this dye is given in the *Dictionary*. In collecting the powder, the ripe fruits are placed in a cloth or sack, and beaten until the glandular pubescence is removed. In some districts the fruits are simply rubbed between the palms of the hands, or are kneaded with the feet on the ground. The powder thus obtained is then sifted to free it from the fruits and broken pieces, and in this condition it is ready for market. Through careless collection or fraudulent admixture, the commercial article, however, is often met with in a very impure state, and this may partly account for its neglect by the Native dyers and the decrease in its consumption.

Collection.

Adulteration.

The following abstract of the available information regarding the chief localities and collecting areas may be given here :—

Bengal.

Bengal.—The tree is fairly abundant in the forests of Puri and Singhbhum, but is scarce in other localities. In the Puri Division it is said to occur in abundance in the southern tracts. It grows wild in the forests, but attains greatest perfection in open situations. Flowers and fruits heavily on lands leased to the Khonds, who clear away all other tree growth, and carefully prune the trees every year. In the thick forests it bears few flowers and fruits. The flowering season is in December, and the fruits mature in January to February. The fruit of the Bengal plant is larger than that of the United Provinces, and doubtless yields a more abundant and better colouring matter. The dye was formerly procurable in large quantities from Raman Lall Das of Elam bazar, Birbhum, at Rs. 13 to 14 per maund.

Season.

Supply.

U. Prov.

Abundance.

United Provinces.—Occurs in great quantity throughout the Kumaon, Garhwal, and Ganges Sub-Himalayan Forest Divisions. It grows wild, for the most part associated with *sál* (*Shorea robusta*). Is common in the Dun; in a few places might be said to form almost the principal tree met with. In spite of its prevalence, there is now, however, no trade in the dye, which could be landed at a railway station for Rs. 10 to Rs. 12 per 100 lb.

Panjáb

Prices.

Panjáb.—Very abundant in the Nurpur forests, Kangra. About 30 maunds are annually exported from Nurpur, where it is sold at the rate of 4 seers per rupee. The cost of 100 lb. would thus be Rs. 12-8, or, delivered at the nearest station, Patankot, would come to Rs. 16. At Amritsar it is said to fetch Rs. 20 a maund. *Kamela* is imported into Rawalpindi from the Hoshiarpur district at the latter price. The tree grows in abundance in the Simla forests, but the dye is not gathered.

ombay.

Bombay.—The Belgaum district is the principal collecting ground for Western India. About 4,000 lb. are sold locally every year at 4 to 6 annas per lb. The price of 100 lb. delivered at Belgaum railway station is Rs. 12-8.

adras.

Production.

Madras.—Widely distributed in the Gamsur taluk of the Ganjam district, the annual output varying from 30,000 to 35,000 lb. The cost price at Madras, including transport and delivery, is Rs. 20 to Rs. 40 per 100 lb. In Madras City there is no local demand for *kamela*, and the dye from Ganjam is all shipped to England and the Continent.

urma.

Burma.—More common in Upper than in Lower Burma. The dye collected is estimated to cost at least double what it does in North India. There do not appear to be any regular market rates, but the prepared powder can be obtained in the jungles at Rs. 5 per viss.

Indian
Methods.

Indian Methods of Dyeing.—Hooper gives the following account of the method of dyeing pursued in Belgaum :—"Two lb. of silk and 1 lb. of carbonate of soda are placed in a vessel of water and boiled for a short time. As soon as the silk softens, it is removed. In the same water are then placed 20 tolas of *kamela* powder, 2½ tolas of *jínjili* (Sesamum) oil, ½ lb. of alum, 1 lb. of carbonate of soda (in addition to the 1 lb. previously used). This mixture is boiled for a quarter of an hour, and then the silk is replaced in the vessel and taken out after another quarter of an hour's boiling. The colour is deep yellow." In the Central Provinces, in dyeing *tasar* silk, the powder is first mixed with the ash of the myrobalan (*Terminalia Arjuna*) and then put in water and allowed to stand till the sediment subsides. The water is then decanted into another vessel in which is placed finely powdered *lodh* (*Symplocos racemosa*) bark. The *tasar* silk is next soaked for six hours in the preparation; then taken out and dried, put back in the fluid, dried and again submerged till the fabric obtains the desired shade.

Mulberry Silk.

Tasar Silk.

Medicine.—*Kamela* is used as an anthelmintic for the expulsion of tapeworm, but its utilisation is said to be almost obsolete, and in 1898 it was omitted from the British Pharmacopoeia. The seeds yield 5·83 per cent. of a bland oil. According to Gamble, the wood is of little use as timber, but is valued as a FUEL. The bark has been reported to be used for TANNING leather, but Prof. Hummel of Leeds found only 6·5 per cent. of tannin in a sample submitted to him for examination. [Cf. *The Bower Manuscript* (Hoernle, transl.), 1893-7, 103, 186; *Pharmacog. Ind.*, iii., 296-300; Lawrence, *Valley of Kashmir*, 1895, 68; *Monographs, Dyes and Dyeing*:—Fawcett, *Bomb.*, 1896, 31; Halder, *Madras*, 1896, 8; Russell, *C. Prov.*, 1896, 19-20; Hadi, *U. Oil.
Timber.

ALT LIQUOR and **Indi n rew i g**.—The manufacture of BEER embraces two distinct operations—**MALTING** and **BREWING**. In the time of Herodotus (450 B.C., bk. ii., ch. 77) there was no separate name for beer; he accordingly speaks of the Egyptians as making wine from barley. Dioscorides, Galen and others condemn beer as prejudicial to the head and nerves.

istory.—The Hindus, as well as most of the aboriginal tribes of India, have been acquainted with both distilled and fermented beverages from very ancient times. But it is curious that while full particulars exist regarding the more advanced art, viz. that of distillation, the rationale of malting as a distinct stage in the production of fermented beverages does not appear to have been understood. Indeed it has been contended that, even in England, malting as a separate operation was not known until the time of Henry VIII., when the use of hops was also discovered. A fermented but non-distilled liquor may be said to have been prepared all over India, the materials varying according to the region or people, but in no instance has malting as a distinct and necessary stage been recorded. And what is perhaps even more striking, a fermented beverage made from grain would seem, so far as India is concerned, to have been more closely associated with the Mongolian than with the Aryan races. With the latter branch of the human family sweet liquids, such as honey and water, cane-juice and water, or the sap of various palms, were fermented into beverages that would more closely correspond with the ancient mead of England or the ales subsequently in favour, than with the beer of modern trade. It would be thus easy to understand why the art of malting was not known, since unnecessary, indeed almost impossible, under these circumstances. The most general Indian name for fermented sweet liquors is possibly *tári*, though *sendhi* is sometimes used almost synonymously, while *pachwai* (or *handia* and *marua*) denote malted and fermented beverages made from grain, mostly rice, though barley and millet are also utilised (see p. 840).

The English word "beer" came through the Anglo-Saxon *beor* and the German *bier*—words which indicate the grain used in the fabrication of the beverage. The Asiatic word which in meaning most closely approaches "beer" seems to be *buzah* or *buza*, a Turkish word adopted into Persian and ultimately into many languages in India and Africa. It is, however, the name more used by the well-informed, *pachwai* being the every-day word for beer or malted liquor made from grain. Shaw (*Travels, etc.*, 1757, 407) speaks of the Egyptians making a fermented and intoxicating liquor, known as *bouzah*, from barley. Moorcroft (*Travels*, 1819-25, i., 162), while describing Ladakh, says that the inhabitants make "a sort of beer called *buza* from barley, the grain of which is parched and ground, and the flour mixed with rice which has been softened by steeping in water. The powder of the root of some bitter and aromatic plant that grows higher up in the mountains is added to the mixture, and the whole is put into a press to squeeze out the water, d dried. When required for use a piece of the dry cake is thrown into a vessel of water, d in

Buzah.

the course of three or four days fermentation takes place and the liquor is ready for drinking." In another passage, Moorcroft remarks, "The Tibetans never drink plain water if they can avoid it. The wealthier drink grape-juice and water, or sherbets; the poorer, a beverage called *buzza* by the Kashmiris, and *chang* by the Tibetans, which is made from barley. The grain is boiled until it is soft, and then dried; to about 10 lb. of this softened grain, three ounces of the dough used for wheaten cakes, but dried and pounded, are added, and the mixture is put into a bag and kept in a warm place until it ferments, which it does usually in two or three days. Equal measures of the prepared barley and cold water are put together in an earthen vessel. After standing for two days the fluid is strained off; a similar quantity of water is again added, and treated in the same manner, and the beverage is the liquor called *chang*." "The grains remaining after infusion are dried, and ground into flour." The above passages bring to mind the account of *buzeh* as given by the Emperor Baber in his *Memoirs* (1525, 283, 294), speaking of Sewad and Bajour (practically the same country), and thus three hundred years before Moorcroft's time. The passage has already been quoted under Eleusine (p. 520), and there would seem little doubt that the substance called *kim*, which was "round like a loaf," was the softened grain (whether barley or *marua*), with its ferment and bitter flavouring ingredient, taken from the cloth in which squeezed to deprive it of its moisture, and thus compressed into what might easily be described as a sort of loaf. Aitchison (*Fl. Lahul, Journ. Linn. Soc.*, 1869, x., 76) says that "from barley, as well as from rice ('*drai*,' '*dai*') a kind of beer is made, called *chung*." In making *chang*, a ferment is used, called *pab*, imported from Ladakh in the form of dry yeast. "The Lahulees admit their ignorance as to its nature and their non-ability to make *chung* without it." In the Hemp Drugs Commission's Report (1894, i., 157) mention is made of a liquid preparation used in Sholapur, Bombay, under the name *boja*, which consists of a gruel made of *juar* (Sorghum, p. 1040) flavoured with hemp and a little *Nux vomica*.

Tibetan *Chang*.

Kim.

Buzza.

The practice of making *buzza* or beer from barley is thus quite as ancient in India, very possibly, as in Europe. In passing it may be added that the great conquering Emperor Baber tells us he did not like "*buzeh*" because of its bitter flavour—the Indian objection to-day to European beer. (See *C. abis sativa*, p. 257.)

Naga *Dzu*.

Under Coix (p. 396) particulars will be found of the Naga hills beer, known as *dzu*. This is, undoubtedly, a fermented beverage made either from coix or rice or both mixed, the one fermented and the other not. Grain is placed in a large wooden trough and hot water poured over it. It is then left to malt, and, when this stage is complete, a further quantity of boiling water is added. In three days' time the liquor is in prime condition, and by the fourth or fifth day it becomes intoxicating. It has already been pointed out that the dispersion of coix grain over India and Burma accompanied the Mongolian invaders, and further that the name *kasi* or *kasai* or some obvious derivative from that word was conveyed to remote countries and into diverse tongues.

Ferments.

Fer. ents.—Bergtheil (*The Study of Fermentation as Applied to Agriculture*, in *Agri. Journ. Ind.*, i., pt. i., 68-75; pt. iii., 230-6) reviews some of the more interesting modern opinions regarding FERMENTATION. Among all races and in every age, he says, we find a knowledge of some means for the production of alcohol, all fundamentally depending on the fermentation of sugar. In many instances the initial action is the conversion of starch into sugar by an enzyme action,—the "malting" of barley. The grains are placed under conditions favourable for germination, and when the production of a soluble, easily assimilable food for the infant plant has been accomplished, the grains are killed. The further stage, namely, the fermentation of the sugary fluid into alcohol, is ordinarily accomplished by a fungus, known as yeast. "In Western countries," writes Bergtheil, "yeasts and their actions have been carefully studied, and pure cultures of special yeasts, which have been found most suitable for the production of the particular type of fermentation desired, are deliberately introduced and their growth most carefully regulated and guarded; in other cases, such as those we are familiar with

in India, wild yeasts are allowed to gain access from the air and grow in the liquid to be fermented, but under all circumstances a yeast or closely allied organism is necessary to the process."

From the facts already briefly reviewed, it may be inferred that this art of fermentation is fairly understood in India. In most *Excise Reports of Bengal* mention is made of a ferment known as *bakhar*—a compound prepared from the roots and leaves of several plants (names unknown, but innocuous) (see *pirits*, p. 1047). In most cases the yeast used is conveyed from one brew to another. The bakers of the lower provinces of India, for example, regularly purchase their supply from the palm-wine (*tari*) manufacturers. In Upper India numerous ferments are known. For example, while travelling in Kullu and Ladakh my attention was drawn to the ferments employed by the people in these countries. I found that in Kullu the brewers of *sur* (grain beer) sent, just as Moorcroft tells us, up country for the root of a herb which they employed in brewing. In Kullu this is known as *mathosan*, and seems to be a species of *Ligusticum*. The root is reduced to powder and mixed with damp barley flour. Fermentation is soon set up, and the mixture is then baked into cakes and dried. These are sold under the name *dhehi*, and are said to preserve the fermentative germ for an almost indefinite period, and may be used either by the baker or the brewer as desired. In Ladakh I was unable to discover the plant employed, but the cakes are there known by the name *paps* (see above, *pab*). [*Cf. Ann. Rept. Ind. Mus.*, 1894-5, 35.]

Bakhar.

Mathosan

Paps.

In Manipur I discovered that the powdered stems of a leguminous plant (possibly a species of *Millettia*) were employed as the fermenting material, and Mr. C. B. Clarke says that in the Khasia hills the people procure fermentation from the flowering spikes of a *Rhyncospora*. [*Cf. D.E.P.*, v., 131-6; Lawrence, *Valley of Kashmir*, 1895, 82.]

Hops and Substitutes.—On more than one occasion the effort has been made to cultivate hops (*Humulus Lupulus*) in India, but with indifferent results. The amount required by the brewers in India is annually imported. Hooper (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1906-7, 12) gives the results of his chemical examination of a sample of hops grown in Kashmir. By way of comparison, he exhibits the amounts of resin (ascertained by Coez's benzol method) in certain trade samples:—Californian, 21.0; East Kent, 18.7; Kent, 17.8; Bohemian, 15.6; North French, 14.8; Kashmir, 13.2; and other Indian samples, 12.9. Thus Kashmir is not far behind French hops.

D.E.P.,
iv., 302-7;
v., 130.
Hops.

Indian Grown.

By the Indian makers of liquors, various substances are used as substitutes for hops, the most general being the distiller's bark (see *Acacia leucophl a*, p. 15), but in this connection it may be of interest to invite attention to the suggestion that the *soma* of the ancient classical writers may have been the astringent stems of *Ephedra* (*D.E.P.*, iii., 247-51) employed in place of hops, and not as itself the source of the liquor of which so much has been written.

Soma.

Barley.—All forms of barley (p. 643) are not equally suitable for brewing any more than all forms of coix are suited (see p. 396). The best Indian barley comes from Northern India (United Provinces and South Panjáb). Plumpness of grain and uniformity in weight are desirable. The finest Indian samples weigh 56 lb. per bushel. The grain must also be bright in colour and not "steely"—the condition of most of the samples from the plains. But above all, it must be living and capable

arley.

Special
Qualities.

of active germination during malting, and must not have germinated before reaching the brewery. Damaged grain will rot during malting, and thus lower very greatly the value of the material. [Cf. *D.E.P.*, v., 128.]

The grain must be thoroughly screened and winnowed before it is placed in the steeping-vats. It is now conveyed to the malting-floor, where it softens and germinates. Simultaneous and uniform malting is essential. When malting is completed, the grain is again screened to remove the rootlets, then crushed, infused with water and hops added. The infusion is next fermented, and shortly after the liquor is ready for bottling and casking.

Indian Indigenous Brewing.—No one has hitherto attempted to produce a definite statement of the art of brewing and of the beverages produced for the whole of India. In the *Excise Reports* issued annually by the various Provincial Governments, brief paragraphs now and again deal with what appear to be beverages akin to beer and ale. As already explained, *pachwai* is made from fermented grain, mostly rice; it is thus a form of beer, but when distilled it becomes a kind of spirit or whisky, and in that case is called *phatika* or *madira*. On the other hand, toddy or *tari* (palm juice) fermented, but not distilled, corresponds very closely with the theoretic definition of ale, and when distilled becomes the spirit generally called *arak*. But palm juice is often drunk without being fermented, and is then spoken of as "sweet tari." For this purpose the law requires that a private person tapping his own trees must wash the interior of the collecting vessels with lime-water so as to prevent fermentation taking place. Similarly a sweet drink or fermented ale is often prepared from *mahua* flowers.

In the *Excise Reports* for both Bengal and Assam, *pachwai* and *tari* are mentioned. (See *Oryza* (Revenue), p. 840.) The licenses granted for home-brewing of *pachwai* are explained: these are issued (mostly to hill tribes) without limit as to quantity, but at a fixed annual fee. The beverage cannot, however, be sold. In the Central Provinces the revenue from *tari* consists of license fees paid for the right to manufacture and to vend. But *pachwai* and *sagda* are in these provinces spoken of as "Native Beer." [Cf. Hooper, *Rept Labor. Ind. Mus.* (Indust. Sec.), 1903-4, 35.] In the reports of the United Provinces reference is given to *tari* (the juice of *Borassus*), to *sendhi* (the juice of *Phoenix*), to *boza*, a fermented liquor made from rice, and to *darbahra*, a fermented beverage from various herbs (not known). Of Madras, mention is made of both sweet and fermented "toddy" collected from the cocoanut, sago, palmyra and date palms, also from a palm not previously recorded as affording the juice, namely the *dadasal* or *dadsel* (*Arenca Wightii*). Of Bombay toddy, it is said the revenue in 1903-4 came to Rs. 15,52,000. This was raised both by a tree tax and a vendor's license. The chief trees tapped are the date palm, the *brab* (*Palmyra*) and the cocoanut. The total number of trees tapped in 1903-4 was 231,245. Unlike Madras, tree-tapping for sweet toddy is not permitted, as fermentation is said to be set up immediately the juice is drawn from the stem. In a special experiment separately reported, thirty-two *brab* trees yielded in Salsette during the month—February 16 to March 15, 1904—a total of 176 gallons of toddy. The Burmese reports speak of "fermented" liquors under two headings—(a) other than *tari*, and (b) *tari*. The consumption of fresh *tari* is allowed without being subject to a tax, and the owners of trees may sell the juice obtained from their trees to professional *tari* makers without paying any fees. Of the non-*tari* beverages, mention is made of *kaung*, *seinye*, *hlawza* and *seye*. These are said to be manufactured from rice, fermentation being procured by yeast. It would seem that a mistake may have been made regarding both the grain and the ferment. Coix is certainly largely employed by the hill tribes, but the ferment need not be yeast as understood in Europe. (See *Bassia*, pp. 118-9; *Borassus*, pp. 170-1; *Caryota*, p. 286; *Cocos*, pp. 361-2; *Phoenix*, p. 886; *Setaria*, p. 988; *Spirits*, p. 1047.)

European Beer.—Turning now to Indian beer brewed after the European method. In the writings of the early European visitors to that country, frequent mention is made of "beer" or of "country ale," but whether these were malted beers or merely the various sweet-liquor beverages already indicated, under the name toddy or *tari*, it would be difficult to say. The English word "toddy" comes, of course, from the Indian *tari*, and was originally, and in India is to-day,

the fermented sap of the *tar* palm. Friar Jordanus (1328 A.D.) speaks of the tree that gives all the year round a white liquor, pleasant to drink, which tree is called *tari*. Sidi Ali Reis refers to the wine obtained in Gujarat from the *tari* tree. On the other hand, Mandelslo (*Travels*, in Olearius, *Hist. Muscovy*, etc. (Davies, transl.), 14; also *Hobson-Jobson* (ed. Crooke), 738 mentions that the captain of the ship in which he journeyed to Surat had excellent good sack, English beer, French wines, *arak*, and that they prepared from the latter good punch (*palepunzen*). Ovington (*Voy. to Suratt*, 1689, 238, 395) says "no Malt drink is made in India"; and again, "Europe Wines and English Beer," though expensive, were "yet purchased and drank with pleasure." Tavernier (*Travels*, 1676 (ed. Ball), ii., 368) tells us that the President gave him a large cask of "English beer" to take with him to Batavia, where none could be had. Birdwood and Foster (*E.I.C. First Letter Book* (Introduction), xxi.) describe the "Cock Ale" in use in the 17th century. It consisted of a bruised cock (the older the better) with 3 lb. of raisins, mace, cloves, etc., two quarts of sack and ten gallons of ale, the whole being left to ripen as with other ales. Punch was another special Indian preparation, and "milk punch" has survived to the present day—the last of a long list of Anglo-Indian preparations—a sort of home-brewed or concocted liquor. [For further particulars see the articles on Opium, pp. 845–61, Tobacco, p. 796, and Spirits, pp. 1043–8.]

Indian Breweries.—Within recent years "Country Beer" has come to mean beer brewed in India after the European system. The first European brewery in India was started in 1825 by a Mr. Henry Bohle at Meerut and Mussourie, but in time the business was taken over by Mr. John Mackinnon. It was not, however, until 1870 that the enterprise became successful. In the meantime, between 1850 and 1860, several breweries were started on hill stations. The official statistics of the larger establishments show that in 1880 there were seventeen breweries in India producing 1,974,578 gallons of beer made after the European system; in 1890, 22 breweries producing 5,192,572 gallons; in 1900, 26 breweries producing 4,947,841 gallons; and in 1904 there were 27 breweries producing 6,219,761 gallons, of which the Commissariat Department purchased 2,839,177 gallons, or a little under half the production. These figures abundantly demonstrate the rapidity with which brewing had developed, and its present position. The breweries and shares of production in 1904–5 are as follows:—Panjáb, 8 breweries and 2,233,955 gallons; United Provinces, 6, and 1,451,796 gallons; Madras, 4, and 416,852 gallons; Mysore, 3, and 700,281 gallons; Bombay, 1, and 558,767 gallons; Baluchistan (Quetta), 1, and 338,580 gallons; Burma (Mandalay), 1, and 306,396 gallons; Central Provinces (Jabalpur), 1, and 130,194 gallons; Bengal (Sonada), 1, and 82,940 gallons.

Consumption of country-brewed (English) beer and ale by the Natives of India is not important, though in some provinces it is more extensive than in others. In Madras these beverages are fairly popular, especially in the hill districts, and in the Panjáb mention is made in the *Eccise Reports* of the demand being on the increase.

External Trade Returns.—The rise and fall in the popularity of imported ale, beer and porter may be said to mark the steady progress of European opinion against the use of strong drinks, and of large quantities of liquors of any kind in tropical countries. The first importation of beer from London recorded in modern commerce may be said to have been consigned from Hodgson's brewery in 1816. This was ultimately known as "Hodgson's Pale Ale." By 1825 the beers made by Bass, Allsopp, Ind and Smith, etc., had found their way to India. It is within the recollection of those still living that a guest was supplied with a basket of four or six bottles of beer and was supposed somehow

Production.

Consumption.

Trade.

Early Imports.

Special Demand.	to get through that supply during the repast. For many years this practice has died out, and the demand been steadily made for a higher grade, lighter beer. This was first met by the Indian brewers. But in time there appeared on the Indian markets not only new firms with light ales and beers, but all the older ones had to respond to the popular desire, and in consequence of this keen competition the Indian breweries lost temporarily some portion of the position they had attained.
Competition.	
Imports.	<i>I ports.</i> —To contrast with the Indian production, already given, the following figures of the import trade may now be recorded. In 1900–1 India received of ale, beer and porter, 3,226,534 gallons, valued at Rs. 46,82,648; in 1902–3, 3,820,938 gallons, valued at Rs. 51,66,378; and in 1904–5, 4,607,530 gallons, valued at Rs. 60,41,973 (£402,798), or say, on an average, two-thirds the quantity brewed in India. In subsequent years the imports were:—1905–6, 5,002,448 gallons, valued at Rs. 62,95,616; and in 1906–7, 4,916,294 gallons, valued at Rs. 60,27,011. Of these foreign imports by far the major portion comes from the United Kingdom. Out of the totals mentioned, for example, the United Kingdom supplied in 1900–1, 3,014,064 gallons; in 1902–3, 3,581,544 gallons; and in 1906–7, 4,506,145 gallons, the only other important country being Germany, with an average of over 200,000 gallons for each of the past five years. The receiving ports are Bombay—the chief emporium for the large military towns of Northern India—followed by Burma, Bengal, Sind and Madras, in the order of importance named. It seems, however, that some of the beers imported from England may be of German origin, though it is perfectly true that Pilsener and Lager are now merely trade names for certain qualities of light beers, and do not necessarily denote German manufacture.

ANGAN ; Ball, *Man. Econ. Geol. Ind.*, iii., 326–32; Bose, *Manganese-iron and Ores of Jabbalpur*, in *Rec. Geol. Surv. Ind.*, 1888, xxi., pt. 3, 71–89; 1889, xxii., pt. 4, 216–26; 1904, xxxi., pt. 1, 47–8; pt. 4, 235–6; Holland, *Rev. Min. Prod.*, in *Rec. Geol. Surv. Ind.*, 1905, xxxii., pt. 1, 13, 55–63; 1906, xxxiii., pt. 2, 94–100; Fermor, *Trans. Min. Geol. Inst. Ind.*, 1906, i., 69–131. In India the commonest ores are *psilomelane*, a complex manganate; *braunite*, a sesquioxide and silicate combined; and *pyrolusite*, or the black peroxide. The peroxide has the following names, *kolsa-ka-pathar*, *ingani*, *nijni*, *iddali kalu*, etc.

Output.	<i>Production.</i> —In 1906 India took the first place among the manganese-producing countries of the world. In 1903 the output was 171,806 tons; in 1904, 150,297 tons; and in 1905, 253,896 tons. The most important deposits occur in the Central Provinces, Madras, Central India and Mysore. In 1905 the production of the Central Provinces was 159,950 tons; in Madras, 63,695; and in Central India, 30,251. Investigations into the manganese-ore deposits of India were started in 1903–4 by the Geological Survey, and a summary of the results is given by Fermor. It has been shown that the deposits can be classified into (a) <i>braunite</i> , <i>psilomelane</i> and <i>pyrolusite</i> , associated with and derived from manganese-bearing silicates in the Archæan schists and gneisses. Examples occur in Nárukot
Classification.	

in Bombay ; Jhábua in Central India ; Bálaghát, Bhandára, Chhindwára and Nagpur in the Central Provinces ; Ganjam and Vizagapatam in Madras. (b) *Psilomelane and pyrolusite*, in part superficially formed on outcrops of rocks of Dharwar age, with which the ores are also embedded. These occur in Singhbhum in Bengal ; Dharwar and Panch Mahals in Bombay ; Jabbalpur in the Central Provinces ; Sandur hills in Madras. (c) *Psilomelane and pyrolusite*, associated with or contained in laterite. These occur in Belgaum and Satara in Bombay ; Jabbalpur in the Central Provinces.

Chief Centres.—Panch Mahals in Bombay ; Jhábua in Central India ; Bálaghát, Bhandára, Chhindwára and Nagpur in the Central Provinces ; Vizagapatam and the Sandur hills in Madras ; and Shimoga district, Mysore, are the localities in which economically important deposits are located and worked.

Uses.—The uses to which the ores of manganese are put are somewhat varied. The peroxide is extensively employed in glass-making, to destroy the green colour. The same oxide is used in porcelain painting and glazing for the fine brown colour it yields, while violet colours are got from the carbonate (*Ind. Art at Delhi*, 1903, 22). The ores are now mainly employed in the manufacture of ferro-manganese for use in the manufacture of mild steel. For use in steel-making, manganese ores should not contain more than 0.25 per cent. phosphorus, nor more than 10 per cent. silica. Under conditions laid down by the Carnegie Steel Company, ores containing less than 40 per cent. manganese and more than 0.27 per cent. phosphorus or 12 per cent. silica may be rejected at the option of the buyer. Holland deplores the exports, since “the whole industry is at present equivalent to a heavy loss to the country.” The ore exported is worth perhaps Rs. 30 a ton, whereas India gets merely the margin left after paying the heavy freight charges, and possibly Rs. 15 a ton can be regarded as the profit divided between the railways, the miners and the owners. He then concludes : “If a flourishing steel-manufacturing industry existed in the country, much of the manganese would be retained in India, and the lower-grade ores would be economically developed. As it is, our manganese-ore is being exported to the three great steel-producing countries—England, United States and Germany.”

Uses.

Ferro-
manganese.India's Share in
Profits

Trade.—As regards foreign trade, the Exports have in recent years shown a considerable increase, especially in 1905-6. In 1900-1, they amounted to 2,613,394 cwt., valued at Rs. 12,51,639 ; in 1904-5, to 3,618,909 cwt., valued at Rs. 24,07,681 ; and in 1906-7, 9,859,855 cwt., valued at Rs. 70,88,280. The largest quantity goes to the United Kingdom, viz. in 1906-7, 4,392,130 cwt. Then follow the United States, 2,786,400 cwt. ; Belgium, 1,971,614 cwt. ; France, 669,710 cwt. ; Holland, 40,000 cwt. In the same year the share of Bombay in the exports was 7,010,863 cwt. ; Madras, 2,130,701 cwt. ; Bengal, 718,291 cwt. Tables showing the variation in the price of manganese ore at the United Kingdom ports since 1890 are given by Holland. In 1903 the price for ore carrying over 50 per cent. of the metal, delivered at United Kingdom ports or at New York, ranged between 9 and 10 pence per unit, or in other words, an ore containing 52 per cent. manganese would be valued at 39 shillings a ton. These prices have considerably risen since, and during 1906 reached 16 pence per unit, the higher rates having greatly stimulated production in India.

The Mango Tree, *am, uli, jegachu, ghariám, tsaratpang, marka, mawashi, mad, mangas, mámadi, mavina, thayet*, etc. A large evergreen tree of the Tropical Himalaya, at 1,000 to 3,000 feet, from Kumaon to Bhutan, the Khasia hills, Burma, Oudh, lower hills of Bihar, and in the Western Peninsula from Khandesh southwards. According to De Candolle it is a native of the south of Asia or of the Malay Archipelago.

The mango has been known and cultivated all over India from a very remote epoch. It is closely connected with Sanskrit mythology, and finds a place in old Hindu tales and folklore. Mention is made of it by Friar Jordanus, who wrote about 1328, and by most of the early Indian travellers. Varthéma in 1510 describes it under the name of *amba*, and Baber, in 1526, speaks of the excellence of the fruit. Again Garcia de Orta, in 1563, writes that those of Hormuz are so good, when in season, that no other fruit can be sold; he then describes the various kinds known.

Cultiva-
tion.

Cultivation.—Mangoes can be grown from seed, but it is the general belief that seedlings rarely produce fruit equal to the parents, and the usual method of propagation is by inarching. According to Maries, the best place to plant the mango is on a raised, well-drained piece of land with a good depth of soil. The nature of the soil does not appear to interfere much with the growth of the tree. In Bengal it succeeds equally well on a rich, deep river deposit, on clayey or on sandy soil; and in Gwalior, Maries wrote that fine trees were grown on *kankar*, i.e. soil with a large proportion of lime nodules.

Soils.

Inarching.

Inarching.—The "stones" are usually sown at the time the fruit is in season, and the plants raised from them are potted to be grafted by inarching with desirable plants. This is accomplished during the setting-in of the rains in the second year of the growth of the seedling. At the close of the rains the union is usually complete. The essential points in this method of grafting are to bring the cambium of the stock and scion together before the graft is completely severed, the parts being bound together so as to exclude air and water and keep the plants healthy during a short growing season. Care should be taken that the scion be of the same thickness as the stock.

Planting Out.

Planting Out.—The best season for planting out the young grafts is the monsoon. The following is a brief account of the method recommended by Woodrow (*The Mango, Cult. and Varieties*, 1904, 11). Having selected the plot of ground, holes should be dug about 3 feet in dimension. The centre of the holes should be about 20 feet distant from each other. About 20 lb. of fresh bone manure should be placed in the bottom of each. The soil on the margin should then be drawn in to a depth of about 9 inches, and the surface soil, mixed with manure, placed on the top. The holes are now ready to receive the grafts. The soil that is left over is put round the margin as a ridge, or *thala*, to form a dam which causes the water given to the young graft to sink

Manuring.

Distance Apart.

near the root. Firm stakes and shade are desirable during the following six months, and the intervening land may be cultivated with moderately irrigated and richly manured crops till the trees have attained flowering size. In five years the plants should be fit to bear a considerable quantity of fruit. When fruiting age is attained, there is no necessity for irrigation from the time the rain ceases in September till the young fruits appear; thereafter, irrigation about once in fifteen days is desirable while the fruits are increasing in size, but may be discontinued when ripening approaches. The surface soil should be kept in a loose, friable state to cause the water to pass downwards. The general flowering season is from January to March, and ripening from May to August, but varieties flower and ripen at all seasons.

Fruiting Age.

Seasons.

Flowering and
Fruiting.

Fruit.—The cultivated kinds of mango are very numerous, but the reader need only be referred to the list given by Maries in the *Dictionary*, and to the accounts by Firminger (*Man. Gard. Ind.* (ed. Cameron), 1904, 256–61) and by Woodrow (*l.c.* 25–32). An interesting paper by Maries in the *Journal of the Royal Horticultural Society* may also be consulted. The two principal localities in India where the finest fruits are said to be produced are Mazagon at Bombay and Malda in Bengal. On the other hand, the fruit ripens so badly and is so much diseased in Assam that it is hardly ever seen to be cultivated, except as a shade-tree. Maxwell-Lefroy gives an account of the Mango Weevil (*Agri. Journ. Ind.*, i., pt. ii., 164–5) which is so very destructive to the fruit.

Fruit.

Best Localities.

Mango Weevil.

Besides being eaten as a ripe fruit, numerous preparations are made of it. When green it is cut into slices, and, after extraction of the stone, is put into curries, or made into pickles with other ingredients or into preserves and jellies. When young and green it is boiled, strained, mixed with milk and sugar, and thus prepared as the custard known as *mango-phul*, or dried and made into the Native *ambokhur*. When very young it may be cut into small pieces and eaten in salad. So again, the ripe fruit is used in curries and salads, and the expressed juice when spread on plates and allowed to dry is formed into the thin cakes known as *ambasath*. Attempts to bring the fresh mango on the London market, at a paying price, have hitherto been unsuccessful, but if it could be conveyed cheaply to England, a trade that would rival the fruit of the West Indies might be immediately anticipated. In times of famine the kernels are eaten. Preserves, chutnies and pickles made from mango fruit are largely exported to England and elsewhere. In MEDICINE, the ripe fruit is considered invigorating, fattening, laxative and diuretic, but the fibrous rind, as well as the unripe fruit, are astringent and acid.

Preserves and
Pickles.

Medicine.

Ti ber.—According to Gamble, the WOOD is used for planking, door and window-frames, in Calcutta for packing-cases, and in Bihar for opium and indigo boxes. Canoes and *masûla* boats are also made of it, and in Dehra Dun and some other tea districts it is in large demand for tea-boxes. Hooper (*Rept. Labor. Ind. Mus* (Indust. Sec.), 1906–7, 8) says that samples of the resinous substance procured from the tree were found to contain 79 per cent. of resin and 15 per cent. gum. Some samples also contained an insoluble gum like tragacanth. The bark and leaves yield a yellow DYE of which little use is made; one of the curiosities of the industrial uses of the tree is the *peori* (or Indian yellow) made from the urine of cattle fed on the leaves. (See *Coal Tar Dyes*, pp. 345, 707.)

Cassava, Tapioca, Manioc, Mandioca, *maravuli*, *marachini*, *simla-alu*, *simul-alu*, *pulu pinan myouk*, etc. According to De Candolle, this is a native of America, but cultivated for so long that the wild parent is no longer recognisable. At the present day there are many widely different races. Some botanists, moreover, regard *M. palmata* as a separate species, others only as a variety of *M. utilisissima*, from which it differs chiefly in the absence of the acrid taste and poisonous principle of the latter. On this account *M. palmata* is known as the sweet, while the other form is the bitter cassava (see p. 444).

Poisonous
Property.

Cassava is cultivated in most of the provinces of India, and in view of the fact that it is a drought-resisting plant, requiring only about 14 to 16 inches of rain per annum, there has been considerable discussion as to whether its cultivation should not be more widely extended, in view of its value in times of famine. The soil should be rich and light. Propagation is carried on by cuttings from the stem, 4 to 8 inches long, which are half buried in the soil at an angle of 45° and placed in rows 4 feet apart. Planting can be done during the whole year, but the best time is at the close of the cold season. Irrigation is employed in some parts, chiefly about Pondicherry and Travancore, but hardly elsewhere. During the first two months the young plants require a moderate supply of water. After the crop is planted, no special cultivation is necessary except to keep the soil free from weeds.

The time the crop takes to mature depends on the particular race grown. Most require about twelve months, though some only six and others as many as eighteen. The yield per acre is very variously stated. In all cases it is large, running from about 2,500 lb. to as much as 30,000 lb. or more (*Agri. Ledg.*, 1904, No. 10, 144-5).

From the roots, various preparations are made. The preliminary operations are the same. The roots are scraped, carefully washed, and then reduced to pulp by being passed through rollers. Subsequent stages vary according to the product required, the most important of which are couac, cassava meal, Brazilian arrowroot and tapioca. Couac is a coarse meal obtained from the pulp by expressing the juice and then pounding and drying the remaining particles. Cassava meal is simply couac of a greater degree of fineness. Brazilian arrowroot is the starch washed out of the root, and tapioca is the same slightly parched. In Cuddalore and Pondicherry the roots are sold after having been part boiled (*Agri. Ledg.*, l.c., 125). The juice of the tubers of the bitter variety can be converted by boiling into a valuable product widely known as *cassareep*. It is a wonderful antiseptic, will preserve fresh meat for considerable periods, and is also the chief ingredient in many sauces.

It was formerly supposed that the root consisted chiefly of starch with a varying quantity of prussic acid, which latter in the case of the "sweet" cassava was confined to the bark, but in the "bitter" occurred throughout the root. To this prussic acid the numerous cases of cassava-poisoning which have at various times occurred were said to be due. Leather, however (*Cyanogenesis in Plants*, *Agri. Journ. Ind.*, 1906, i., pt. iii., 223-4), states that a number of varieties were

PRUSSIC ACID

examined by him at Poona in January 1904, and that none were found to contain any prussic acid as such, but that all manifested a cyanogenetic glucoside "associated with an enzyme which has the property of causing the splitting up of the glucoside, and the consequent formation of prussic acid." In exemplification of this he gives particulars regarding the glucoside *dhuririn* in the leaves of the *juár* (*Sorghum vulgare*, see p. 1040) and of the glucoside in the present plant. "I was able," he adds, "to establish three facts: *firstly*, none of the varieties contained any prussic acid as such; *secondly*, all the varieties, irrespective of the colour of the petiole or other botanical features, contained a cyanogenetic glucoside, which varied much in amount; *thirdly*, this glucoside is associated with an enzyme which has the property of causing the splitting up of the glucoside, and the consequent formation of prussic acid. As in the case of *juár* leaves, it is only necessary to crush tapioca root with water in order to bring about this change. The amount of prussic acid varied very much; from some roots 1·5 grains of prussic acid per pound of root was obtained, from others only one-tenth as much." "Boiling the root is quite sufficient not only to destroy the enzyme, but also to allow the glucoside to pass out into the water, for the root splits up freely." Dunstan and Henry (*Pois. Prop. Beans of Phaseolus lunatus*, in *Journ. Board Agri.*, 1908, xiv., 730) are of opinion that the application of enough heat to destroy the activity of the enzyme present should render such food material harmless. (See *Phaseolus lunatus*, p. 880.) In MEDICINE tapioca has the same properties and uses as starch. Hanausek (*Micro. Tech. Prod.* (Winton and Barber, transl.), 1907, 45) gives interesting details of his microscopical examinations of the grain. [*Cf. Shortt, Man. Ind. Agri.*, 1885, 307-10; Nicholls, *Textbook Trop. Agri.*, 1892, 274-8; *Pharmacog. Ind.*, iii., 203-5, app.; Sawyer, *Tapioca Cult. in Travancore*, in *Proc. and Journ. Agri.-Hort. Soc. Ind.*, April to June, 1897, xi., 666-74; *Agri. ANU AND F RTILI R.—The most general vernacular names in India for manures are:—

khad, *khau*, *páus*, *khadar*, *sar* or *sarra*, *kallar*, etc.; *páusa*, Sansk.; and *zibl*, Arab.

D. P., v., 167-77
Manures.

Speaking of India as a whole, it may be said that systematic manuring is almost entirely neglected by the Natives. From the most ancient times they have been accustomed to observe a casual system of manuring, namely the collection of such substances as are inexpensive and easily obtainable. Moreover, by the very general employment of dried cow-dung as fuel and the utter neglect, through insufficient litter, to conserve cattle urine, they have been deprived of the most important source of all fertilisers and the one readiest to hand, namely farm-yard manure. Caste prejudices, moreover, have to a great extent forbidden the employment of many manures such as bone, animal refuse, night-soil, etc. Still, here and there the value of manure is fully understood (as, for example, in some parts of the Western Presidency); and in the treatment of special crops (such as sugar-cane) manuring is regularly practised. But neither example nor precept have, as yet, succeeded in arousing the average Native cultivator to a sense of the benefits likely to accrue from an extended use of manure beyond that pursued by his ancestors. But in all fairness it must be added that in the majority of cases this apathy proceeds far less from ignorance than from inability to purchase soil-fertilisers. The most urgent necessity of agricultural progression in India is, therefore, a system of fuel and fodder reserves calculated to release the supply of farm-yard manure for its more legitimate purpose, that of a soil-fertiliser.

MANURES AND FERTILISERS

Water and
Manure.

Voelcker (*Improv. Ind. Agri.*, 131) has very properly said: "Whilst a few soils, such as those of silt-renewed tracts, the black cotton-soil, and newly reclaimed or virgin land, may not require manure, it may be said of the greater part of India that the necessity for using manure is enormous, and the supply of it is notoriously inadequate. Water and manure are interdependent, and, just as the former has been, and is still being provided for, so must attention be given to the supply of manure. These two factors, water and manure, constitute the *raiyat's* great needs, and in their supply consists, very largely, the Improvement of Indian Agriculture."

In dealing with Manures and Fertilisers it may be convenient to assort them under three main groups, namely Animal, Vegetable and Mineral Manures:—

Animal
manures.

1. Animal Manures.—These may be referred to the following (a) Farm-yard Manure; (b) Town Refuse and Night-soil (Poudrette); (c) Bones; and (d) Guano.

Farm-yard.

Farm-yard Manure.—It would be impossible to review here the very large amount of interesting new information that has accumulated during the past decade or so regarding Indian farm-yard manure and its uses. The chief contributors in this direction have been Benson, Leather, Lehmann, Mehta and Mollison. Leather, in his *Final Report*, points to the fact that throughout the greater part of Gujarat, farm-yard manure is extensively utilised *as a manure, not as a fuel*, and with much skill and intelligence is stored in specially prepared pits. Benson deals with a somewhat similar state of affairs in Coimbatore and Salem. But what is more to the point, the people who do so find no difficulty in growing for themselves, in the form of hedges and otherwise, the fuel that they require for domestic purposes, and thus disprove the oft-affirmed opinion that, having no other fuel, the people of India are driven to burn their manure. In many parts of India even the surplus cow-dung—the proportion that is not required for fuel—is rarely appreciated to the full extent as manure. It is all too often thrown into waste hollows or on the roadsides or on the bank of the village tank, in most cases becoming a source of danger in place of an advantage. Very rarely indeed is any effort made to preserve and utilise the cattle urine. This is a most unfortunate state of affairs seeing that it has been shown in Europe and America most conclusively that farm-yard manure is, perhaps, the best and certainly the most economical of all manures. It contains all the constituents of plant food; is a most valuable and convenient source of nitric acid; its nitrification is most active at the very period of greatest growth; as a manure it is less liable to be washed out of the soil than most artificial nitrogenous fertilisers; it permanently enriches the soil; and acts under all climates, on all soils and with all crops.

Fuel Supplies.

Cattle Urine.

Nitric Acid.

Results.

Leather says that Indian experiments show that when an application of 6 tons to the acre is given, an increase of 300 to 400 lb. of wheat may be the result. After ascertaining that such an allowance would not be beyond the capabilities of the cultivator, he adds, "consequently these experiments really illustrate what the value of the cattle manure is in terms of food-grains." Moreover he confirms the opinion, advanced originally by Voelcker, that "Indian dung is not poorer than English." [*Cf. Leather, Note on Value of Ind. Cattle-dung, in Nagpur Exp. Farm Rept., Annex. F, 1893-4, 1-10; Econ. Util. of Cow-dung and R&B, in Ind. For., 1886, xii., 541-5; Benson, Care and Manag. Farm Man. in South India, Bull. 1894, No. 31; Watt and Mann, The Pests and Blights of the Tea Plant, 130-4; Clouston, Cattle Manure, in Agri. Journ. Ind., 1907, ii., pt. iii., 261-9.*]

Night-soil.

Town Refuse, Night-soil and Sewage.—The question of the disposal of night-soil and its utilisation for manurial purposes is one which has been, of late years, earnestly considered throughout India by all Governments and Municipalities. In large towns night-soil and street refuse are removed at the expense of the local authorities, but the question arises as to its disposal. The most general practice is to trench it into fields and by its means to reclaim waste land. For this purpose, in some cases deep, in others shallow trenches are employed. Leather remarks, "It is at Allahabad Grass Farm that I have found the most perfect methods employed. The night-soil is

Disposal.

Shallow
Trenching.

here usually trenched, but instead of the trenches being narrow and deep, about 1 foot by 1 foot, they are really shallow beds, about 14 by 5 feet and only 3 inches deep. A cart-load of night-soil is thrown on, and the excavated 3 inches of earth put back upon it. I have several times, when at Allahabad, dug up these "beds" in which the night-soil had been placed only a few days previously, and found no objectionable odour." "In deeper trenches the decomposition takes naturally longer, but at Meerut I found that a fortnight had been ample for the purpose." In the shallow system the manure is distributed over a larger area, and thus more usefully; with deep trenching as much as 200 tons per acre may be given in the year, whereas one-tenth or one-twentieth would have been ample. In many instances a kind of snow-plough is run over the ground and shallow furrows thus excavated, into which liquefied night-soil is run.

Deep and Shallow Trenching.

Of the manufacture of poudrette it may be said there are many advantages, and disadvantages. Of the latter, the chief is the fact that the atmosphere of the locality in which the pits are located becomes almost uninhabitable. Still, the poudrette, when prepared, may be carried to great distances and thus utilised over a wide area. The increasing demand for the poudrette of certain towns is indicated by the continuous increase in the price at which it is disposed of. In fact it may be said that the night-soil of many cities has become a source of revenue, so that much progress has taken place. All that is necessary is to extend the demand from the vicinity of the cities to that of the villages, in order to secure a much-needed sanitary reform and great agricultural advance. [Cf. Buck, *Employ. City Refuse for Agri. Purposes at Farukhabad*, 1872; Moreland, *Use of Town Drainage as Manure*, in *U. Prov. Bull.*, 1901, No. 18; *Ann. Rept. on Working of Sewage Farm, Manjiri*, 1902-3; Leather and Mollison, *Agri. Value of City Sewage in India*, in *Agri. Ledg.*, 1903, No. 2; Joshi, *The Util. of Night Soil as Man.*, *C. Prov. Bull.*, 1901, No. 5.]

Poudrette.

Bones (see p. 169).

Bones.

Guano and Allied Manures.—The excrement of fowls, pigeons, wild birds and bats, etc., may be said to be all forms of the substance known as GUANO. It is one of the most highly prized animal manures in European countries, and owes its value to the readily soluble ammonia, phosphates, potash and soda that it contains. A small amount of this substance is annually imported into India, and it has been ascertained to be of special value in protecting sugar-cane cuttings from being attacked by white-ants. Mollison says it is one of the best manures for wheat, 2 to 3 cwt. an acre being sufficient. It acts rapidly and is expended almost entirely on the crop to which applied.

Guano.

For Wheat.

Indian guano is not unknown. It is procured from the caves in Karnul and of the Andaman and Nicobar Islands. The former is possibly mainly the produce of bats, and the latter of the edible swallows (see *Birds*, p. 138). The imports during the past five years have averaged 2 tons, valued at Rs. 700. [Cf. *Encycl. Brit.*, 1880, xi., 233 *et seq.*; Spons, *Encycl.*, 1882, i., 358; ii., 1258; *Journ. Soc. Chem. Indust.*, 1887, vi., 228; 1888, vii., 84 *et seq.*; 1899, xviii., 213 *et seq.*; Thorpe, *Dict. Appl. Chem.*, 1899, ii., 504 *et seq.*; *U.S. Yearbook, Dept. Agri.*, 1899, 274 *et seq.*; *Board of Trade Journ.*, 1901, xxxiii., 72 *et seq.*; 1902, xxxix., 201-2.]

Indian Supply.

Fish Manures. (see pp. 543-4).

Fish.

Vegetable.

II. Vegetable Manures.—Many vegetable substances, such as boughs and leaves of bushes and trees, indigo refuse, wood-ashes, weeds of every description (green, dry and burnt), oil-cakes, tank deposits consisting largely of aquatic weeds, etc.,—these and such like are, when obtainable, fairly extensively used as manure here and there all over India. They are usually thrown on the surface of the land and ploughed or hoed into the soil in a fresh state, where they only too frequently become a nidus for insect pests and fungal blights. Except by market gardeners and by tea and coffee planters, pits or heaps are rarely resorted to for the storage and maturation of vegetable manures, and as often as not the stuff casually secured is thrown on the field at the wrong season, and thus becomes next to useless. The following are the chief manures of this class :—

Mould.

Green Manuring and the Assimilation of Nitrogen.—As with the clover in D.E.P., E ope so with several leguminous crops in India, their value as alter ting v., 174.

Green
Manuring.

crops or as green manure was appreciated for centuries before their exact action was understood. The chief crops of this nature are *Cajanus* (see pp. 197-8), *Cicer* (see p. 298), *Crotalaria* (p. 433), *Dolichos* (p. 504), *Indigofera* (pp. 672, 679), *Phaseolus* (pp. 225, 879), and *Vigna* (see p. 1107). It is significant that all these, and a good few others that might be mentioned, belong, like clover, to the special sub-order of leguminous plants that have been shown to possess in the strongest degree the power of producing on their roots, warts that harbour bacterial organisms that have the power of fixing the free nitrogen of the air and thus enriching the soil. Unless, therefore, leguminous crops have been grown so extensively as to render some other plant a desirable rotation, it is preferable in green manuring to select a leguminous crop for that purpose. In that way the advantages of green soiling as well as the supply of nitrogen to the soil may be secured. A green manure should, in fact, be a plant that develops rapidly; should give the largest volume of green vegetation; should be as deep-rooting as possible, thus opening up the soil to a fair depth; should be sufficiently hardy as to flourish under what might be called unfavourable conditions; should occupy the soil and the atmosphere at a season when the crop it is designed to assist is either not on the soil or not growing vigorously at the time; should return more to the land than it has removed; should serve to retain manurial constituents that might otherwise be washed out; and lastly, should easily rot when hoed into the ground. [Cf. Gilbert, *Fixation of Free Nitrogen*, Lect. deliv. at Cirencester, July 1890; Lawes and Gilbert, *Sources Nitrogen of Legum. Crops*, 1892; Warrington, *Six Lect. on Rothamsted Exper. Stat.*, etc., U.S. Dept. Agri. Bull., 1892, No. 8; Frankland, *The Chem. and Bacteriology of Ferment. Indust.*, in *Journ. Soc. Arts*, 1893; *Agri. Ldg.*, 1893, No. 20, 141-3; 1894, No. 7, 189-200; 1897, No. 8, 173-5; *Nitrogen and Forest Crops*, in *Ind. For.*, 1897, xxiii., 439-52; *Green Manuring*, in *Journ. Leguminous
Crops.

Advantages and
Requirements.

Jumping.

Burning or Rábing and Jumping.—Burning of weeds in heaps collected all over the fields is less commonly seen in India than in Europe. Aboriginal tribes are fond of cutting down the trees and brushwood and firing these on the surface of the soil—a process of both clearing new land and manuring it with vegetable ash. This is known as *jumping*. A civilised modification of this is pursued in Western (and to some extent also in Southern) India. Seed-beds or even whole fields are manured by what is called *ráb*. This consists in burning the surface soil by means of layers of dried manure, leaves, branches and weeds. After the burning has ceased, the soil and ashes are ploughed in, and thus mixed together. The reader will find much useful information regarding the production of *ráb* soil in Mollison (*Textbook Ind. Agri.*, i., 83-5).

Rábing.

Silt.

Top-dressing of Soil by silt from canals and streams or by the soil from dried-up tanks, *bhils*, etc., is a subject that has attracted much attention recently. To the tea-planter a dressing of "peat *bhil* soil" has been proved in some cases profitable, but it is feared soil of comparatively little value has, in many cases, been used in top-dressings, with the result that the cost has far exceeded the value. Much, therefore, depends on the quality of the *bhil* soil available. What may be called peaty soil is formed by the decay of many generations of rank-growing plants, especially if the decomposition has been accomplished under water. Soil of that nature is most valuable, and has with great advantage been used in many tea estates. [Cf. *Pests and Blights*, l.c. 122-30.] For many other crops silt deposits have been highly commended. For example, of this nature may be mentioned the special cultivation of ground-nuts in South India, manured with tank-soil (see p. 79). [Cf. with Leather, *Agri. Ldg.*, 1897, No. 8, 172-3; *Silt of Rivers as Manure*, in *Journ. Board Agri.*, 1897, iv., 351.]

Peat-soil.

D. P.,
v., 463-79.
Oil-cake.

Oil-seed Cake—The Indian cultivators fully recognise the value of oil-seed cake or the refuse of such, both in feeding cattle and as manures of great value. The edible sorts of oil-cake, such as Linseed (see p. 731), Rape and

ustard (p. 184), Sower (p. 283), Til (p. 986), Cotton (p. 613), Earth-nut (p. 82) and Coconut (p. 360) are much favoured as cattle foods, while the others that may be classed as non-edible are largely used as manure, the most important of this latter class being Castor-oil (see p. 922); but Poppy (p. 860) and ahua (p. 120) may be added. With highly profitable crops, such as sugar-cane, many of the edible cakes are occasionally employed as manures. Mollison points out that the cultivators in this respect often act against their own interests, since the castor cake very often fetches a higher price than some of the edible cakes which they refuse to use as manure. The advantage to India of the oil-seeds being expressed in the country, instead of being exported, has been repeatedly urged (Voelcker, *l.c.* 104). Profitable labour would be secured for many persons and a larger percentage of cake retained and to a greater extent than at present, very possibly, returned to the soil. The *Annual Reports* of the various Agricultural Departments and Experimental Farms of India have for many years past abundantly demonstrated the value of the cakes as special manures. [Cf. Leather, *l.c.* 157-62; Mollison, *l.c.* 122-33; Lehmann, *Comm. Fertil.*, in *Agri. Journ. Ind.*, 1906, i., pt. ii., 123-6; also see article Oils and Oil-seeds, p. 818.]

Advantages of
Oil Mills.Production of
Cake.

Special Plants as Manures.—*Adhatoda* (see p. 25); helpful vegetation (see pp. 54, 113-4). Plants with milky sap, such as *Calotropis* (pp. 53, 206) and *Euphorbia* (p. 530), are specially preferred; the refuse of indigo (see, see p. 679); and many other such substances are valued as manures and often resorted to by the cultivators. The reputation of *Adhatoda*, both as a manure and a poison to destructive organisms that appear in the flooded rice-fields, is specially worthy of attention.

III. Mineral Manures.—Though several very valuable manures of this kind exist plentifully in many parts of India, their value and uses are hardly anywhere appreciated. Some of these have already been so fully dealt with in other positions in this work that all that need be necessary is to furnish cross references:—

Lime.—(See p. 712). As a rule lime is present in such abundance in the agricultural tracts as scarcely to require its addition as a manure.

Lime.

Gypsum.—(See p. 717).

Gypsum.

Ammoniacal Liquors and Ammonium Sulphate as Manures.—(See pp. 48, 346.) Sir John Lawes has pointed out that the objection to sulphate of ammonia and all other "highly nitrogenous" manures, is that "they use up certain natural ingredients in the soil, which when exhausted cause the plant to fail." In a further communication he condemned sulphate of ammonia, because it removes lime from the soils. Where the percentage of lime is naturally low, as for example in the tea lands as a whole, it should not be used, or only in exceptional cases. All artificial manures have the further objection that in countries subject to heavy rains, soluble manures are very readily washed out of the soil, so that their action is often only temporary; a fall of rain of only a very few inches may suffice to remove them entirely. For crops that occupy the soil for brief periods only, such as wheat and barley, if given in combination with potash either present in the soil or added as an ingredient of the special manures, these chemical nitrogenous fertilisers may be of special value. [*Journ. Soc. Chem. Indust.*, 1899, xviii., 486; Mollison, *l.c.* 117-8; Watt and Mann, *l.c.* 154-5.]

Ammonium
Sulphate.

Nitrates.—The nitrates of potash and soda are both largely employed as manures. In a crude sort of fashion the Native cultivators of India here and there show that they are aware of the value of crude saltpetre as a manure by the value they place on surface soil collected near the homestead. Certain localities, as for example Bihar, have been noted from time immemorial for the large stores of saltpetre found naturally in the soil, and such localities have accordingly been famed centres for the production of the salt. Saltpetre is specially valued as a manure with tobacco, sugar-cane, and garden crops generally (see Saltpetre, p. 974). [Cf. Mollison, *l.c.* 119-21; Leather, *Calcium Nitrate d Nitric Acid*, in *Agri. Journ. Ind.*, 1907, ii., pt. ii., 209-10.]

D. P.,
v., 175-6.

Saltpetre.

Potash Manures: *Pearl Ash, Kainit, etc.*—Saltpetre is valued not only as a source of nitrogen, but on account of its pot h. Continuous cultivation and removal of crops must, therefore, gradually lower the stores of this all-important material. With the return to the soil of decomposed vegetable matter or of plant ashes, the potash is to some extent stored. But sooner or later it must

Potash.

	be added as manure if fertility is to be preserved. To the Natives of India potash may be said to be summed up in Pearl Ash (see p. 49). Plant ashes have been for centuries valued for high-class cultivation. The subject is closely akin to <i>rābing</i> and <i>jumming</i> (see above, p. 770). The value of wood-ashes as manure will be found discussed in many Indian publications, such as the <i>Indian Forester</i> (1879, iv., 284-5). Rice husk, almost worthless as a cattle food, is of great value as a manure, because of the high percentage of potash it contains. So also the refuse skimmings, in the process of sugar manufacture, are much valued, and indigo refuse is also rich in potash. Recently, however, certain natural minerals have come into the market as special potash-yielding manures. Of this nature is <i>kainit</i> , which contains 13 to 14 per cent. of potash. When calcined it is greatly improved, and may be given at from 2 to 4 cwt. to the acre. It is useful on light lands rather than on clay soils. Large beds of this substance have been discovered in Germany.
Rice Husk.	
Phosphates.	Phosphates and Phosphatic Manures, Basic Slag, etc. —The phosphoric acid required by plants is one of the soil ingredients liable to be exhausted by continuous cropping, and must be supplied in the form of manure. It is on this account that pastures are liable to get worn out. The principal manures of this class are bones, superphosphates and reduced phosphates. Space cannot be afforded to revert to the subject of bones and the special preparations made from them (see p. 169). But it may be here observed that large fossiliferous deposits have been found in many countries rich in phosphates. Holland (<i>Rev. Min. Prod.</i> , in <i>Rec. Geol. Surv. Ind.</i> , 1905, xxxii., 112-4) says of India, "One regretful feature" . . . "is the absence, in a country where agriculture is such a prominent industry, of any phosphatic deposits of value, and a further circumstance to be regretted is the continued export of phosphates in the form of bones, due primarily to the fact that, being without means for the manufacture of cheap sulphuric acid, superphosphates are not made in the country, and the little that is used is imported from Europe." "Amongst the phosphatic deposits of India, the principal and perhaps the only one worth considering is the deposit of phosphatic nodules of the septarian kind, occurring in the cretaceous beds of the Perambalur taluk, Trichinopoly district, Madras Presidency. Dr. H. Warth, in 1893, estimated that to a depth of 200 feet the beds contained phosphates to the amount of about 8 million tons, but the nodules are distributed irregularly through clay, varying, in the different deep excavations made, between 27 and 47 lb. per 100 cubic feet, and in some shallow diggings 70 lb. per 100 cubic feet. Analyses of these nodules show them to contain from 56 to 59 per cent. of phosphate, and about 16 per cent. of carbonate of lime, with considerable variations in different nodules. The alumina and oxide of iron vary between 4 and 8 per cent." Two attempts made to utilise these deposits have proved futile, and it is believed there is no present prospect of mining for export. [<i>Cf. Hooper, Effects of Phos. Man. in Jalap Cult.</i> , <i>Pharm. Journ.</i> , July 1896; <i>Sly, Min. Fertil. in Ind.</i> , <i>Agri. Journ. Ind.</i> , 1906, i., pt. iii., 243-6; <i>Leather, Mem. Dept. Agri. Ind.</i> , 1907, i. (Che . ser.), 45-57.]
Bones.	
Sulphuric Acid.	
Phosphatic Nodules.	
Basic Slag.	Basic Slag , a by-product in the manufacture of steel, and until recently a waste product, came into use as a phosphate and lime manure. It is ground to a fine powder, and in soil moisture is at once dissolved and rapidly absorbed by the roots. As it contains much iron it is not suited for soils already rich in that substance. [<i>Cf. Hughes, Journ. Soc. Chem. Indust.</i> , 1901, xx., 325 <i>et seq.</i> ; <i>Hooper, Agri. Ledg.</i> , 1898, No. 20.]
Manure Works.	Indian Manure Works. —It would, perhaps, be invidious to attempt an enumeration of the bone-mills of India (further than has already been given, p. 169), since these by no means represent all the manure works, nor the firms that trade in indigenous and imported manures.
Trade.	Trade. —The traffic in manures is not an extensive one, and, when bones are eliminated, is hardly worth mentioning. The total exports in 1904-5 were valued at Rs. 43,77,841, of which Rs. 37,51,480 were bones, and in 1906-7 at Rs. 1,01,54,892, of which Rs. 55,45,241 were bones. But one point is worthy of consideration, viz. while the exports of raw bones have been declining steadily for some years past, the exports under the heading of Others (excluding oil-cakes) have been steadily increasing. In 1900-1 the exports of bones were valued at Rs. 58,41,916,
Bones.	

THE ARROWROOT PLANT

MA A TA
ARUNDINAC A
Arrowroot

and the Others at Rs. 71,503; five years later (1904-5) the Others had expanded to Rs. 6,26,361. It is believed this increased traffic may, to some extent, represent the expansion in the manufacture of special manures, the surplus, not required for India, being exported. Lastly, this increase in the exports of manures from India has been chiefly from Madras and Burma. The imports of foreign manures are so unimportant as scarcely to deserve notice. In 1904-5 they were valued at Rs. 50,980, and in 1906-7 at Rs. 55,105, and came almost exclusively from the United Kingdom.

Exports of
Special
Manures.

Imports.

ARANTA A UNDINAC A, Linn.; *Prair.*, Beng. *Plants*, 1903, ii., 1047-8; SCITAMINEÆ. West Indian Arrowroot, *tikhar*, *tavkil*, *ararut*, *kúaka neshasteh*, *kuwa mavú*, *tavaksha*, *pen-bwa*, etc. A native of Tropical America and of the West Indies, cultivated in India. It yields the genuine or West Indian Arrowroot, so called to distinguish it from East Indian, the produce of *Curcuma angustifolia* (see p. 444), with which it is often confused.

D.E.P.,
v., 1 0-4.
Arrowroot.

Cultivation.—The cultivation of this rhizome is briefly as follows :—Drills are made about 3 or 4 inches deep and 2 feet apart. On these the roots are planted in May, at a distance of a foot and a half apart, and covered over by earth. As the plants grow, they should be earthed up in the same way as potatoes. They require good, rich soil and plenty of water, which should, however, be withheld for a month or two previous to gathering the crop (Firminger, *Man. Gard. Ind.* (ed. Cameron), 143-4). Of Cuttack, Banerjee states that it grows well on rather sandy soil, and of Bombay, Woodrow remarks that as regards soil it is by no means fastidious, "fine sand at Nariad and loam and clay-loam at Poona being equally suitable provided heavily manured and irrigated." Flowering takes place in August, and in January or February the crop may be taken up. The maturity of the rhizomes may be ascertained by the falling down of the leaves. In digging up the crop it is impossible not to leave behind small portions of the rhizomes, and from these fresh plants spring, so that it is often difficult to eradicate the plant from soils on which it has been once grown. The smaller rhizomes and the pointed ends of the larger ones, on which the "eyes" are situated, should be kept for fresh planting. According to Woodrow, the produce in green tubers is generally 6 to 7 tons per acre, though over 12 tons have been produced at Poona. According to Nicholls the rhizomes contain 20 per cent. or even more of starch, and in Natal as much as a ton of arrowroot has been made from the rhizomes derived from an acre. It is generally said that cultivation should not be attempted in localities remote from a liberal supply of water, since irrigation may not only be required by the crop, but water is essential in the manufacture of the arrowroot.

Cultiva-
tion.

Soils.

Seasons.

Propagation.

Yield.

Manufacture.—The method of preparing the arrowroot is simple. The rhizomes after being well washed are scraped with a knife to remove the rind, and at the same time diseased or imperfectly formed portions are picked out and thrown away.

Prepara-
tion.

Washing.

The rhizomes are then pounded to pulp in a mortar or reduced to that condition on a grater. The pulp is then thrown into a vessel of water, which becomes turbid or milky while a portion of the pulp remains suspended as a fibrous mass. This fibrous portion is lifted out, rinsed, pounded once more and again thrown into water, lifted out a second time, rinsed, and then thrown away. The milky-looking fluid thus obtained from these several washings is now strained through a coarse cloth to remove any particles of the fibre and other impurities, the liquid being thus passed into another vessel, and when the sediment has settled, the water is gently poured off and clean water added. This is again stirred up and strained through a fine cloth, and, on settling, the water is once more carefully and gently drained away. The sediment that remains now consists of pure arrowroot, and is dried on sheets of paper by exposure to the sun, and packed ready for the market. It is a tasteless and colourless powder, which might be spoken of as consisting of pure starch granules. [Cf. Hanausek, *Micro. Tech. Prod.* (Winton and Barber, transl.), 1907, 43-4.]

West versus
East Indian.

The genuine West Indian arrowroot may be readily distinguished from East Indian by its pure white colour and by its swelling in boiling water. [Cf. Milburn, *Or. Comm.*, 1813, ii., 207; De Candolle, *Orig. Cult. Plants*, 1882, 81-2; Mason, *Burma and Its People* (ed. Theobald), 1883, ii., 209; Nicholls, *Textbook Trop. Agri.*, 1892, 278-83; *St. Vincent Arrowroot*, *Kew Bull.*, 1893, 191; also *Bermuda Arrowroot*, 1898, 50; *Manuf. of Arrowroot in Ceylon*, *Trop. Agrist.*, Feb. 1, 1895, xiv., 557; Dodge, *Useful Fibre Plants of the World*, 1897, 235; Semler, *Trop. Agrik.*, 1900, ii., 747-66; Woodrow, *Gard. in Ind.*, 1903, 480-1; A. W. and M. W. Blyth, *Foods, etc.*, 1903, 141, 144-5; *Agri. Ledg.*, 1904, No. 10, 135; *L Agri. Prat. des Pays Chauds*, 1904, iii., 757-8.]

D.E.P.,

. Royle, *Wight murkula, pathor, tar, veri, kurang, kharchu, shengori*, etc. A climbing shrub of the Himalaya, from Sikkim westwards, ascending to altitudes of 7,000 feet. It yields a fibre from which fishing-nets, lines and strong ropes are manufactured.

. **tenacissi a**, *Wight & Arn.*; Rajmahal Hemp, *tongus, jiti (chiti), babal jak*, etc. A climbing shrub of the Sub-Himalayan tracts from the Jumna to Nepal and extending South to Oudh, Bihar and Chota Nagpur; Chittagong and Upper Burma.

Fibre.

The bark of the stem yields a valuable FIBRE, which was said by Royle to be the second best in India. By the hill tribes it is used chiefly for bow-strings and netting. The fibre was examined in 1886 by Cross and Bevan, who reported that it was of excellent quality and in point of fineness and durability ranked next to reha. More recently a sample was sent to the Imperial Institute for examination. It was found to contain little or no lignocellulose, and to be exceptionally resistant to the action of alkalis. The remarkable quality of the fibre was also shown by the unusually high percentage of cellulose and by the large increase of weight on nitration. The length of the ultimate fibre was found to be 10 to 30 mm. Specimens were also submitted to leading firms of fibre brokers for commercial valuation. One reported that the fibre, though short, was of great strength, and another that it was very strong, but harsh. The sample, of a length of 12 to 15 inches, was valued at £15 to £18 per ton, but it was stated if fibre 30 to 35 inches long could be sent, its value would probably be £35 to £40 per ton. In view of these facts the question arises whether experiments in cultivating the plant might not be undertaken, and whether the fibre could be successfully treated by machinery. [Cf. Royle, *Fibrous Pl. Ind.*, 1855, 304-5; Dodge, *Useful Fibre Plants of the World*, 1897, 235-6; Dunstan, *Rept. on Marsdenia tenacissima*, *Imp. Inst.*, July 9, 1903; *Agri. Ledg.*, 1904, No. 8.]

Blue Dye.

. **tinctoria**, *R. Br.*; *ryom, riyong, kali lara, mai-nwai*, etc. A large climbing shrub of the Sikkim Himalaya, Assam, the Khasia hills, Northern Burma and the Circars. This species also yields a fibre, but is more especially interesting on account of the indigo DYE yielded by the leaves. At the beginning of last century Roxburgh recommended its cultivation, but nothing appears to have been done, nor has the value of the dye been commercially tested. (See Indigo, p. 663.)

AT AND ATTING MATERIAL ; Long, *Indig. Pl. Beng.* (gives list of mats and matting materials); *Bast Matting*, in *Journ. Agri.-Hort. Soc. Ind.*, 1857, ix., 10; also 1859, x., 342; Birdwood, *Indust. Arts Ind.*, 1880, ii., 223-4, 298; Mukharji, *Art Manuf. Ind.*, 1888, 307-14; *Journ. Ind. Art and Indust.*, 1890, iii., 31; Gee, *Monog. Fibrous Mat. Pb.*, 1891, 6, 7, 10, 11, 14, etc.; *Japanese Floor Matting*, in *Journ. Soc. Arts.*, 1892, 919; Watt, *Ind. Art at Delhi*, 1903, 447.

For information regarding woven mats, the reader should consult *Carpets and Ru s* (pp. 271-6), and for the chief matting materials, the list below. The most famous of the so-called mats are the grass-mats—(a) of Pálghát on the Malabar Coast of Tinnevely, and Ganjam in South India; (b) of Midapur and Calcutta in Bengal; (c) the *sitalpati* mats of Eastern Bengal and Assam (Sylhet); (d) the coir mats of South India and Bengal; (e) the *munj* mats of Allahabad, Agra and Delhi in North India; (f) the date and other palm-leaf mats used all over India, more especially in Western and Southern India—in Bombay known as *shaelu* mats; and lastly, (g) ivory mats, woven from strips of ivory so fine that they resemble the strands of *sitalpati* (see *Ivory*, p. 698).

Chief Forins.

Mats or rather screens (*tatties*) made of the sweetly scented *khas-khas* are hung in front of doors, etc., to afford shade and to cool, by evaporation, the air which passes through their moistened texture. Bamboo mats are manufactured here and there all over India, and in Bengal more especially *darmá* mats (those constructed of reeds, see *Phragmites* below) are all but universally used in house-construction. The traffic in *darmá* mats must, therefore, be very great, and give employment to a far larger number of persons than can be learned from published statistics. In some of the jails aloe-fibre mats are produced and find a fair market, while cane mats are not uncommon. These are formed by selected canes being placed parallel to each other and bound in position by cross-ties. They are exceptionally strong, and specially valued in public offices where there is much traffic.

Tatties.

The following are the chief matting materials of India:—

Agave (see p. 43). In the Panjáb, the fibre of two species is a good deal used in jails for making *daris*, mats and ropes. It is beautifully white and takes dye much better than even *munj* (*Saccharum*), but it is neither so strong nor so durable. The plant is a slow grower and liable to exhaustion. [Geé, *L.c.* 4.]

Aloe.

Ar dñaria race osa, Munro (see *Bambusa*, p. 99).

Bamboo.

a busa Tulda, Roxb. (see *Bambusa*, p. 101).

Cane.

Clinogyne dichoto a, Salisb.: *Fl. Br. Ind.*, vi., 258; *Agri. Ledg.*, 1896, No. 41; Nisbet, *Burma under Brit. Rule and Before*, 1901, i., 383; SCITAMINEÆ. The *sitalpati*, *muktá-páta*, *murta*, *thin*, *godúnika*, *bhúdra*, etc. A woody shrub of Eastern Bengal, Assam, Burma and the Malay Peninsula. It thrives on moist ground, which need not be specially prepared, and it can be reproduced by cuttings as well as by transplantation of shoots.

D. P.,
vi., pt. i.,
216-7.
Sitalpati.

From the stems are prepared the famous *sitalpati* or "cool mats." For the manufacture of the finest mats, the *murta* should be cut when one year old. The split stems as prepared are about 4 feet long, one-twentieth of an inch wide, and as thin as paper. The average size of the mats, when finished, is about that of an ordinary double bed. Owing to their coolness they are much used during the hot weather, both by Europeans and by Natives, being placed beneath the bedding sheets. As a historic fact of some interest it may be here mentioned that formerly the main corridor of the East India House in Leadenhall Street, London, is said to have been lined with this matting. The quality is judged by glossiness, smoothness and fineness of texture, and it is said that over the smoothest even a serpent cannot glide. The price varies from Rs. 2 for the common sort to as much as Rs. 100 for the best qualities. The chief producing

- districts are Faridpur, Bakarganj, Tippera and Chittagong in Eastern Bengal, Sylhet and Cachar in Assam, and Henzada in Burma. The industry is almost entirely confined to women. It has been suggested more than once that this fibre would make an excellent substitute for the Panama fibre in hat manufacture. The plant also yields a pith, which is discarded by the *sitalpati* makers, but which might well be employed as a paper material if procurable in sufficient quantity. [*Cf.* O. W., in *Capital*, April 25, 1901.]
- Panama Fibre.
- Cocor.
- Coccos nucifera, Linn. (see p. 356).
Corypha u bractulifera, Linn. (see p. 429).
Crotalaria juncea, Linn. (see pp. 435-6).
Cyperus tegetu, Roxb. etc. (see pp. 467-8).
edychiu spicatu, Ham.; the *sit-ruti*, *kapurkachri*, *sheduri*, etc. The leaves of this plant are made into the sleeping-mats employed by the hill tribes, where the plant is at all plentiful.
- Calcutta Mats.
D.E.P., iv., 207-8.
- Ibiscus tillaceus, Linn.; a large and abundant bush and affords a fibre obtainable by a process much less tedious than with most other fibre-yielding plants—a fibre which would appear well adapted for the manufacture of mats, ropes, and possibly also paper. In the Panjáb it is occasionally employed in the construction of *charpais*, sides of carts, seats of bullock-waggons and mats. In New Caledonia and Tahiti it is made into fishing-nets (see p. 629).
- Ischæ u angustifoliu, Hack. (see pp. 694, 865).
- D.E.P., iv., 552.
- Juncus effusus, Linn.; *Fl. Br. Ind.*, vi., 392. This common European rush is found in the Sikkim Himalaya and Khasia hills from 6,000 to 10,000 feet. *J. glaucus*, Ehrh. Beitr., which is not unlike the former species, though stiffer and darker, is met with in the Western Himalaya, Nilgiri hills and Ceylon. The European plant is in considerable vogue for the manufacture of baskets, mats and chair-seats, and it is suggested that similar uses might be found for one or both species in India, where they are at present entirely neglected.
- elocanna bambusoides, Trin. (see Bambusa, p. 103).
- D.E.P., v., 317.
- annorhops itchieana, H. Wendl.; *Fl. Br. Ind.*, vi., 429; Gamble, *Man. Ind. Timbs.*, 733; PALMEÆ. The *mazri*, *patha*, *kilu*, *pfis*, etc. Usually a stemless shrub, but occasionally develops a stem 10 to 14 feet long. It is met with in Sind and the Western Panjáb as well as in the Kuram Valley and in Baluchistan, many acres of country about Harnai being covered with it, and ascending the hills to 5,500 feet above the sea.
- Waziri Mats.
- In former times it was common all over Kohát, but railway construction has led to an increased export to the Cis-Indus districts, and the more easily available *mazri* supplies have been exhausted. In 1882 measures were taken to protect the palm. The green leaves are beaten out with a mallet, and the fibre obtained is used for matting, fans, baskets, hats, sandals, nets, etc. Waziri baskets and mats procured at Bannu are famous all over the Western Panjáb. Rope is also made from the stems and leaf-stalks, though apparently it is not very strong. The leaf-bud, young inflorescence and fruit are eaten, and the leaves regarded as a purgative medicine for cattle. The seeds are made into rosaries and exported from Baluchistan (Gwadar) to Mecca. The price of *mazri* matting in Peshawar is about Rs. 8 per 100 sq. yards, and its popularity appears to be increasing.
- Baskets.
- ipa fruticans, Wurm.; *Fl. Br. Ind.*, vi., 424; Gamble, *Man. Ind. Timbs.*, 729; PALMEÆ. The *gúlga*, *golpahal* (fruit), *golpatta* (leaves), *dani*, etc.; a large creeping gregarious palm of the Sundribans, Chittagong, Burma and the Andamans. The old fruits are large, the interior being hard like ivory, but transparent; they are carried to the sea and floated to great distances. The leaf-stalks are used to help in floating *sundri* logs in the Sundribans, also as fishing-floats. The leaves are very largely employed for thatching and in making mats. In the Straits Settlements they are used for covering cigarettes. Toddy is obtained from the spathe (as Linschoten observed in 1598), and the young fruit is edible. Gamble states that the trade in *golpatta* leaves in the Sundribans amounts yearly to about 135,000 tons, valued at nearly Rs. 60,000.
- Thatch.
- Ryza—Rice Straw (see p. 826). In Kullu and Hazara, mats called *mandri* and *phandí*, as also string, are made of rice-straw.
- Rice.
- D. P., vi., pt. i., 4-8.
- Pandanus, the screw-pines, might be described as a genus of palm-like evergreen trees or shrubs, often scandent and possessed of copious and strong aerial roots. They are met with in the moist tropical regions, chiefly Mascarene and Malayan. Hooker (*Fl. Br. Ind.*, vi., 483-7) describes some seven Indian

species, and mentions many other obscure forms. The only species of economic value may be said to be:—

P. odoratiss us, Linn. f. (*P. fascicularis*, Lam.); the *keura*, *kea*, *ketuki*, *keori*, *mugalik*, *thalay*, *talai*, *kaida*, *sathapu*, etc. Common on the sandy coasts of South India, Burma and the Andamans. It forms dense impenetrable thickets in the tidal forests, and is extensively grown as a hedge plant. It is also specially cultivated in gardens in South India on account of the fragrance of its spikes of flowers. These, tied up within the few adjacent leaves, are sold in the market towns, and may be seen in shops and at the railway stations. The women wear the fresh flowers in their hair and use them as offerings at the temples. From them is also prepared *keura*, perhaps the most characteristic and most widely used perfume of India. The soft floral leaves and pulp of the fruit are also eaten. The leaves afford an excellent fibre which is employed for nets, sacks, brushes, mats, etc. [Cf. Marco Polo, *Travels* (ed. Yule), ii., 250; Clusius, *Ananas silvestris*, *Exot. Pl.*, 1605, 285; *Ain-i-Akbari*, (Jarrett, transl.), ii., 126; Forster, *Pl. Esc.*, 1786, 38-41; *Taleef Shereef* (Playfair, transl.), 141; *Rept. Ind. Hemp Drugs Comm.*, i., 156.]

Perfume.

Phœnix, several species (see pp. 834-5); also Basket- and Wicker-work (p. 115). *Phragmites*; of the reeds proper there are two species, *P. communis* (*dila* or *dámbú*), met with in the marshes and on the margins of lakes in North-West India up to altitude 10,000 feet, and *P. karka* (*nala*, *nal*, *nar*, *sur*, *kaing*, *karka*, etc.), found in the swamps of the more tropical India.

Date.

D.E.P.,
vi., pt. i.,
218.

Reeds.

The former is employed on the Dal Lake of Kashmir as the *radhs* that constitute the foundation of embankments and floating islands. The culms of both species are extensively utilised all over India in the construction of chairs (*morhas*) and baskets; they are also largely used for lutes and the tubes of smoking-pipes (*hukahs*). Split open they are made into mats, and thus constitute one at least of the sources of the *darmá* mats of Bengal. These are produced cheaply and in great abundance, being universally employed in house-construction. They are also utilised as lining (dunnage) of ships to protect and isolate cargoes, and they might with advantage be used to line the inside of iron roofing. The flowering stalks are beaten out and afford a useful rope-fibre. [Cf. Lisboa, *Bomb. Grass.*, 116; *For. Admin. Repts.*; *Rec. Bot. Surv. Ind.*, ii., 155, 240, 247, 360.]

Chairs.

Darmá.

seudostachyu (see Bamboo, p. 104).

Saccharu arundinaceu, Retz. (see pp. 929-30).

Munj.

Lac.

Tachardia lacea, Kerr.; for mats made of lac, confer with account given by Birdwood (*Indust. Arts Ind.*, 1880, ii., 223-4). A thread of lac is wound around a stick, and, after drying, is drawn off and broken into sections of three or four turns each. These are then linked together into mats of all sorts of variegated colours.

Typha; *Fl. Br. Ind.*, vi., 488. There are three species of Reed Mace, Elephant Grass or Cat's tail Bullrush, between which, for the present purpose, it is hardly necessary to draw distinctions since their properties and uses are practically identical. These are known as *T. angustata*, the *lukh* of Upper India; *T. elephantina*, the *pater*, *hoglá*, *bora*, *dib*, *pun*, *rámabána*, etc.; and *T. laxmanni*, the *pitz* of Kashmir.

D. P.
vi., pt. iv.,
07-
Elephant
Grass.

The culms, as also the leaves of all three forms, are extensively used in making sieves, thatching huts and house-boats, and in the manufacture of mats, ropes and baskets. In Sind they are also employed in the construction of crude boats called *tirbo*, also floats and buoys to support swimmers. They are much valued for their long roots, which bind loose soils and embankments. The pollen is regularly collected, and on the Indus forms a fairly important article of food, being baked into cakes. Bhaduri (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1902-3, 27) has given the results of his chemical analysis of this article of food. It contains carbohydrate, 44.50; albuminoid, 19.75; cellulose, 17.80; oil, 2.70; the balance is water. The young shoots and tender roots are also eaten, and the lower succulent parts of the fruiting spike, soaked in oil, are used as a torch, whilst the down of the ripe fruit is mixed with mortar as a binding material.

Sieves.

Edible Pollen.

The rushes are split and woven into coarse mats for covering boats and for making walls or partitions of houses. The leaves also find a purpose in the construction of soft matting as, for example, Kullu, Kumaon, Sind and elsewhere. In the Panjáb, *Typha* is generally adopted as a matting material when *mazri* (*Nannorrhops*) is not available. [Cf. *Ain-i-Akbari* (Jarrett, transl.), ii., 123;

MATS AND MATTING

Taleef Shereef (Playfair, transl.), 31; Gee, *Monog. Fibrous Mat. Pb.*, 1891, 2; Dodge, *Useful Fibre Plants of the World*, 1897, 319; etc., etc.]

Khas-khas. *Vetiveria zizanioides*, Stapf; the *khas-khas* (see p. 1106).

Trade. *Trade and Coerce*.—The statistics of mats and matting given in the annual official returns of trade exclude Coir Manufactures, and it is not shown to what extent they include mats or rugs other than grass-mats. The EXPORTS to foreign countries during the years 1899–1900 to 1906–7 showed no great fluctuation in quantity but a remarkable undulation in value, due perhaps to the demand for cheap goods in one year being supplanted by more expensive articles in the next. The highest recorded value was Rs. 2,41,887 in 1900–1. In 1903–4 the amount stood at Rs. 58,754; in 1905–6 was only Rs. 27,267; and in 1906–7, Rs. 47,617. Madras has more than half the trade in quantity but realises less in value than Bombay. The re-exports were at their highest value in 1903–4 (Rs. 26,234), and represented chiefly trade from Bombay to East Africa, Turkey-in-Asia and Persia. Of the IMPORTS a large share should probably appear as Carpets and Rugs, as, for example, the supply (56 per cent.) that comes from Mekran and Sonmiani. Other considerable contributors are China (Hongkong) and the Straits Settlements. The highest value in the years mentioned (1899–1907) was reached in 1904–5 (Rs. 2,94,182), and of that Rs. 1,52,782 and Rs. 49,473 were taken by Bombay and Sind.

Exports.

Imports.

Coir. As regards COIR MANUFACTURES (excluding rope and presumably including some proportion of articles other than matting) the trade is almost entirely concentrated in Madras, which in 1903–4 exported to foreign countries some 473,281 cwt., valued at Rs. 46,78,050, chiefly to the United Kingdom and Germany, the total foreign trade of all provinces having been 483,355 cwt., valued at Rs. 47,90,110. In 1906–7 the exports from Madras were 552,703 cwt., valued at Rs. 55,24,154, and the total foreign trade 559,329 cwt., valued at Rs. 56,00,268. At the same time the Madras Presidency contributed to Bengal and Bombay a fairly large quantity, namely Rs. 9,00,000 worth. (See also *Cocos nucifera*, p. 362.)

D. P., v., 199–203. **Lucerne.** **M DICAGO ATIVA**, Linn.; *Fl. Br. Ind.*, ii., 90; Prain, *Beng. Plants*, 1903, i., 414; LEGUMINOSÆ. Lucerne, Purple Lucerne, or Alfalfa, *vilayti-gawuth*, *hol*, *spastu*, *sebist*, *yurushea*, *beda*, *vilayti-hullu*, etc.

According to De Candolle, the plant is a native of western temperate Asia, and is found apparently wild in Afghanistan and Baluchistan. Stein (*Ancient Khotan*, 1907, 130) speaks of it as extensively cultivated in Khotan and used as fodder. It is now largely grown in many parts of India and affords excellent forage for horses and cattle, if given in moderation. At least two varieties are cultivated, the Kandahar and the Persian or Arabian. The latter is the crop ordinarily met with.

Two Forms.

Seasons. *Cultivation*.—In the Poona district, according to Mollison, the best time for sowing is either early in the rains or between October and December; in the north of India, from the middle of October to the middle of November. The price of seed ranges from Rs. 0–14 to Rs. 1–8 per lb. The usual Native method of sowing is broadcasting on a clean, well-prepared bed, but by this method the field gets foul by deep-rooted grasses and other weeds, and the lucerne fails when it ought to be in full vigour. A good method of cultivation is as follows:—The field should be well ploughed and brought into a thoroughly friable, smooth, clean condition during the rains. In September, 30 cart-loads per acre of well-decayed farm-yard manure should be given. The manure must be evenly spread and mixed thoroughly with the soil. Ridges are then formed

Manure.

BURMESE VARNISH TREE

M LANO A

U ITATA

Lacquer Ware

22 to 28 inches apart, on which the seeds are sown (10 lb. per acre) in a groove along the top, and covered by not more than 1½ inches of soil. Frequent waterings are necessary during the first fortnight. On medium soil, lucerne grown in the above manner requires water every eighth day in the cold season, every sixth day in the hot weather, and oftener if the soil be light. Water should also be given during breaks in the monsoon. It requires liberal top-dressing at short intervals. At least 5 tons of well-rotted farm-yard manure should be applied every third time the crop is cut.

The principal object of the ridge-and-furrow system is to keep the field clean, since the furrows can easily be weeded each time the crop is cut by using an ordinary bullock-hoe. A crop will be well established in six months, and should last for years, yielding at least ten cuts per annum. In 1893-4 the best results obtained on the Poona Farm were as follows:—outturn per acre, 31,816 lb.; value per rupee, 120 lb.; cost of cultivation per acre, Rs. 85-3-8; value of produce per acre, Rs. 265-2-0. [Cf. Bentham, *Rev. of Targioni-Tozzetti*, in *Journ. Hort. Soc.*, 1855, ix., 139; De Candolle, *Orig. Cult. Plants*, 1884, 102; Burke, *Primer on Cult. Crop.

M LANORRHCEA U ITATA, *Wall., Pl. As. Rar.*, i., 9-12, tt. 11, 12; *Fl. Br. Ind.*, ii., 25; *Watt, Kew Bull.*, 1906, 137-47; also *Ind. Art at Delhi*, 1903, 218-24; **ANACARDIACEÆ**. A large deciduous tree of the open forests of Manipur, Burma and Siam, rare in dry forests. It is generally known as **THE BURMESE VARNISH TREE**, and by the following vernacular names, *thitsi*, *kheu*, *suthan*, *kiahong*, etc. (See *emecarpus*, p. 981.)

D.E.P.,
v., 08-10.
Burmese
Varnish.

In addition to affording a useful **TIMBER**, it yields a natural **VARNISH** of great interest and value, and one which may be characterised as having originated several distinct industrial and art conceptions peculiar to the Burmese, Shans and Siamese. In Maymyo the preparation of the crude black varnish may be spoken of as the chief forest industry, but it is also largely extracted in the Monghong State. In fact, wherever the tree abounds the varnish is collected. In such tracts it is rare to find a tree that has not been tapped. It is exported mainly from the Northern and Southern Forest Circles of Burma. To obtain the varnish, V-shaped incisions, 9 inches long and 5 inches apart at the base, are cut on the bark of the trees, the apex pointing down. The tongue of bark within these scars is then slightly lifted up and a specially prepared joint of bamboo driven in horizontally immediately below the apex of the incision. The sap which exudes from the inner bark drains into the bamboo receiver. This is emptied at the end of ten days, when the flow of varnish is observed to become scanty. A second cut is made along each side of the contained tongue of bark, which is also again raised up slightly and the bamboo receiver placed more conveniently to the new scarification. After this has yielded all the varnish that seems likely, a new incision is made a little higher up. It would appear that young trees yield better than fully formed ones. By the tapping process the trees become much distorted, and it is no unusual occurrence to find some that manifest 50 to 60 successive scarifications. One man, it has been estimated, can look after and collect the varnish from 1,200 trees, provided they are not too much scattered. He can scarify and collect from about 200 trees a day. The best season for working is from July to October, and one man may collect from 146 to 182 lb. in one season. In 1904-5, 38,622 viss, and in 1905-6, 36,382 viss, were collected under license and permit. [Cf. *Ann. Rept. For. Admin.*, 1904-5, 55.]

material or moulding substance. It may be coloured with lamp-black, gold-leaf, vermilion (not red lead), orpiment, indigo, etc., and applied with a brush or by the hand direct, or to objects revolving on the turning-lathe. When painted on cloth or paper the form used is very thin and pure, but on drying the articles are found to have been rendered waterproof. As a cement it is largely employed in the Burmese glass mosaics, but by far its best-known property is in the manufacture of the so-called Burmese lacquer ware, of which there are four types and centres of production—Pagan; Prome; Mandalay; and Manipur leather varnish.

Cedar.

It is of considerable economic importance. From the bark there exudes a bright amber-coloured GUM, which is collected in small tears or fragments. This is said to constitute a portion of the commercial "gum gattie," and of "East India gum." It is considerably esteemed medicinally as a stimulant. From the seeds a fixed acrid, bitter OIL is extracted, of a deep yellow colour and disagreeable flavour. As an anthelmintic and antiseptic it is in much demand, and is largely used by the poorer classes for burning, but said to smoke badly. The barks of trees are often painted with it to protect them from insect pests. By the women of Sind it is applied as a hair wash. The chemistry of this oil was fully investigated by the late Dr. Warden, and a detailed account of his results is given in the *Dictionary*. *Nim* oil-cake is regarded as a useful fertiliser. In addition to the gum and oil, the bark, young fruits, seeds, leaves, flowers and sap have all medicinal properties assigned to them or are spoken of as edible. The leaves are utilised to preserve books, papers, cloths, etc., from ravages of insects. They are said, moreover, to be useful in keeping away mosquitoes. Hooper (*Rept. Labor. Ind. Mus* (Indust. Sec.), 1903-4, 30-1) records the results of his investigations. Fresh leaves were distilled in water. It was found that a distinct allyl- or onion-smelling compound was present in the distillate. The powdered leaf, when burnt, gave off an odour found to prove fatal to insects. The extract of the leaves was intensely bitter and contained evidence of an alkaloid.

The sap or *nim* TODDY is yielded by the tree either spontaneously or is extracted artificially. In the former case, a clear and colourless liquid flows in a thin stream or continuous droppings from two, three or more parts of the plant simultaneously for several weeks on end. Artificially it is obtained by exposing a healthy-looking root, cutting it through, and placing a vessel beneath to receive the exuding liquor, which is a refrigerent, nutrient and alterative tonic. The WOOD is durable, has an average weight of 50 to 52 lb. per cubic foot. Its chief use is for cart-construction, ship-building, agricultural implements, and in South India for furniture. The twigs are largely used as tooth-brushes. [*Of. Garcia de Orta*, 1563, *Coll.*, xl.; *Taleef Shereef* (Playfair, transl.), 170; Jacob Breynius, *Icon. Rar. Pl.*, 1739, 15, t. i.; Buchanan-Hamilton, *Stat. Acc. Dinaj.*, 1833, 154; Moodeen Sheriff, *Mat. Med. Mad.*, 1891, 100-5; Banerjee, *Agri. SUPPLY OF MICA

though commonly met with up to 6,000 feet in altitude, and frequently cultivated in India and Burma.

Like the *nim*, this species also yields a brown adhesive GUM and the seeds afford a fixed oil; but these are not important. It has long been used in medicine by the Arabs and Persians, but the Hindus seem to have neglected it in favour of *nim*. The stone from the fruit is employed all over India as a bead, being perforated and strung into necklaces, rosaries, etc., and is supposed to act as a charm against disease. According to most writers, the wood is liable to warp and split, but Gamble states that the samples used at the Imperial Forest School for Museum cases and furniture behaved well. It is handsomely marked and takes an excellent polish. [Cf. *Taleef Shereef*, l.c. 39, 162; *Paulus Aegineta* (Adams, Comment.), 1847, iii., 449-50; Bentham, *Rev. of Targioni-Tozzetti, Journ. Hort. Soc.*, 1855, ix., 177; Moodeen Sheriff, l.c. 99-100; Banerji, l.c. 185, 195; Woodrow, l.c. 233; Firminger, *Man. Gard. Ind.* (ed. . composita, Willd.; *M. dubia*, Hiern (non Cav.), in *Fl. Br. Ind.*, i., 545. The *eisúr*, *kadú-khajur*, *limbarra*, *dingkurlong*, *mallay vembu*, *bévu*, etc. A large deciduous tree of the Sikkim Himalaya, up to 6,000 feet; Khasia hills; hills of Western Ghats in South India and west coast forests from the Konkan south. Gamble states that the wood will probably be found useful for tea-boxes and similar purposes, and that it should be cultivated on account of its rapid growth. In Ceylon, the outriggers of native boats are made of it.

MICA; Ball, *Man. Econ. Geol. Ind.*, iii., 524; Holland, *Mica Deposits Ind.*, in *Mem. Geol. Surv. Ind.*, 1902, xxxiv., pt. 2; *Phosphatic Mica-Peridotites in Lower Gondwana Rocks, Beng.*, in *Rec. Geol. Surv. Ind.*, 1894, xxvii., pt. 4, 129-46; also *Rev. Min. Prod.*, in *Rec. Geol. Surv. Ind.*, 1905, xxxii., pt. 1, 14, 63-9; 1907, xxxvi., 76. The group of minerals known collectively under the name Mica have several characteristics in common, which vary with the combining ratios of the bases and the silica of which they are composed. The light-coloured micas generally belong to the kind known as muscovite, the black to biotite; other varieties are lepidolite and lepidomelane. It has the following vernacular names:—*abraṭ*, *appracam*, *kokabálarz*, *vajrábhra* (black mica), etc.

Sources.—Though mica is one of the most widely distributed minerals in India, its occurrence in plates of sufficient size to be of commercial value is limited to a few tracts. Holland (*Mem. Geol., l.c.*) gives a full account of the geographical distribution of the known mica-bearing areas of India. The most important localities occur in the provinces of Bengal, Madras, Bombay and Burma, but in another publication (*Rev. Min. Prod., l.c.*) he states that Bengal and Madras are the only provinces in which the mica-mining industry can be viewed as established and important. In the official returns, *Financial and Commercial Statistics*, published by the Government of India, particulars are given of factories or works that employ 25 persons or over. Under "Mica Mines" (on that standard) there were in 1901, 17 mines employing 6,668 persons; in 1902, 16 mines employing 7,242 persons; in 1903, 18 mines, employing 6,276 persons; and in 1904, 45 mines, employing 6,559 persons. Including all grades of mica mines, there were 9,165 persons employed on the average during the three years ending 1903, of which 6,694 were in Bengal and 2,471 in Madras. In 1905, 15,244, and in 1906, 15,723 daily workers were recorded at the mica mines.

Output.—As regards the output, Holland observes that the published returns grossly understate both the quantity and value, since they are below the figures usually quoted for the exports. "As the only mica on which royalty is charged is that raised on Government land, and as many mica miners have mines in both Zemindari and Government land, there are obvious reasons for understating the production; and, besides this fact, the flourishing industry of stealing mica diminishes the returns for production without affecting the export figures. A considerable quantity of mica of the poorer grades is consumed in the country for ornamental and decorative purposes, and a small quantity of the larger sorts is used for painting pictures on, in various parts of the country. As far as the figures for quantity are concerned, therefore, the exports cannot be accepted

an approximate expression of the production ; but as regards *value*, the export returns may be accepted as a closer approach to the figures which should express production."

Uses.—The uses of mica depend on its peculiar combination of qualities, viz. its highly perfect cleavage; its transparency to light, together with a comparative opacity to radiant heat-rays; its low power of conducting electricity; its chemical stability; the great flexibility of its folia, combined with a high elastic limit and consequent power to resist violent shocks or sudden changes of temperature. It may be substituted for glass in lanterns, doors of furnaces, windows, as a glazing material for pictures, for backing of mirrors, etc. By far the largest quantity of sheet mica, however, is used for electrical purposes, for covering portions of dynamos and other electrical machines. For similar uses, thin films have lately been used for making the so-called *Micanite*, in which films of mica are made to adhere to one another by a highly insulating cement. According to Holland, the invention of micanite has created a new opening for the use of the smaller grades of mica, formerly rejected as waste. In India itself mica is chiefly employed for decorative and ornamental purposes, e.g. in ornamenting temples, palaces, and many of the banners, robes, etc., employed in ceremonies. In fine fragments or as powder it is also used for ornamenting pottery and fancy cloths, especially the Afridi wax-cloth (see *Carthamus*, p. 232). Finally, it is used to a considerable extent in Native medicine, and even more naturally and successfully as a manure.

Exports.—For the years 1897-8 to 1902-3, it is stated that the mica **EXPORTS** averaged 19,173 cwt. with an annual value of £77,613, or £4.05 per cwt. A table is furnished by Holland that shows the relative contributions of the mica-exporting provinces. The two chief, Bengal and Madras, during the years under review (1897-1903) contributed to the average total as follows:—Bengal, 12,282 cwt., valued at £52,272; Madras, 6,872 cwt., valued at £25,241. Of these exports the United Kingdom took the largest share, amounting on the average to 14,843 cwt., valued at £56,799, or 77.4 per cent. of the total quantity and 73.2 per cent. of the total value. Much of this, however, is sold in the United Kingdom for transmission to the Continent and America. The United States come next, 15.5 per cent. of the average total quantity and 20.1 per cent. of the total value. The mica sent to America, it is stated, brought a higher price, as only the better qualities could face the heavy import duty imposed by the Dingley Tariff in 1897. Turning to the annual statement of the *Trade and Navigation of British India* with foreign countries for the year ending March 1907, we learn that the following were the actual exports from India during the past five years:—1901-2, 16,298 cwt., valued at Rs. 10,50,511; 1902-3, 20,412 cwt., valued at Rs. 13,13,909; 1903-4, 21,548 cwt., valued at Rs. 12,94,453; 1904-5, 19,575 cwt., valued at Rs. 14,68,986; 1905-6, 31,554 cwt., valued at Rs. 23,94,413; and 1906-7, 51,426 cwt., valued at Rs. 38,24,988.

THE ĀL OR ĀCH DYE

M INDIA
CIT IFOLIA
Deccan

The young roots (more especially the root-bark) yield a good yellow Dye, which is used fairly extensively by the Natives of Eastern Bengal and Darjeeling, also by those in Assam, and to a small extent in Burma. In Darjeeling and the Garo hills, McCann writes that the dye is prepared by pounding the bark of the root and boiling it in water, then straining and boiling over again till the required consistency is obtained. In dyeing cotton yarn or cloth, certain ingredients that act as mordants or acids to brighten the colour are used along with the morinda extract, or other dyes are employed along with it, to produce brilliant reds. Duncan (*Dyes and Dyeing in Assam*, 1896, 35) gives full particulars of the system of dyeing with *Morinda angustifolia* that prevails in Assam. Chips of the bark of *letekū* (*Baccaurea sapida*) and the leaves of the *lodh* (*Symplocos spicata*, p. 1053), by most writers said to be the chief mordants employed. [Cf. Mason, *Burma and Its People* (ed. Theobald), 1883, ii., 422.]

Assam.

. citrifolia, Linn.; *M. tinctoria*, Roxb.; Watt, *Agri. Ledg.*, 1895, No. 9, 2 plates. A plant often called the Indian "Mulberry," or Togari Wood of Madras; *āl, āch, bārtundi, surangī, nina, nīna, sira, maddī, nyah-gyi*, etc. A small tree or large bush formerly widely cultivated throughout India; but within the past few years the industry has been entirely ruined and the cultivation practically abandoned.

Togari
Wood.

Cultivation.—The cultivation of *Morinda* has been discontinued, or nearly so, since the introduction of aniline dyes. In many districts where it was formerly a profitable industry, as in the Central Provinces and Berar, it has for several years been practically discontinued. A full account of the methods of cultivation and position of the industry is given in the *Agricultural Ledger* (l.c. 137-9). It is there stated that the crop was formerly very profitable. One of the most striking features was the circumstance that from a perennial tree, which may attain a height of 30 to 50 feet, a biennial field-crop had been produced that rarely exceeded a height of 2 feet, though it flowered and fruited freely.

Cultiva-
tion.
Influence of
Aniline.

Production and
Biennial.

The soil was prepared as for other crops. It was ploughed three times, cleared of weeds, and sown in June. The seed was procured from previous field-crops and put through a process of special preparation. This was the *choti-āl*, and was the crop exclusively grown in certain localities, such as the Anjangaon neighbourhood. In other villages a crop known as *moti-āl* was also grown, the seed for which was obtained from trees which grew near by, and not from the previous field-stock. The fruits were collected, piled in a heap till they turned black and the pulp softened. This was accomplished in three or four days. After separating the seeds by breaking the fruit on stones or by the *mogra* (mallet), the seeds were piled together for fifteen days. To remove the remainder of the pulp the seeds were placed in baskets and sunk in the river and finally spread out to dry. About 40 lb. were drill-sown to the acre. The *moti-āl* often flowered and fruited the first year, and would continue to do so during the second or even third. At the village of Anjangaon, the *choti-āl* crop was usually gathered in the third year and dug up somewhere in November to January. Sandy soils were best suited, black soils being too hard for the roots to penetrate. The Anjangaon cultivators considered the three-year-old crop to be the best. After the roots were dug up and separated from the stems, they were cut into small pieces, spread out to dry, and in eight to twelve days were ready for market. The *āl* crop was followed by cotton, which in its turn was followed again by *āl*.

Dye.

Dye.—A full account of the Native methods of utilising the dye is given in the *Dictionary*. The reader should also consult the *Agricultural Ledger* (l.c. 141-4), where it will be found an account of the process in Gondal, Kathiawar, has been contributed by Mr. M. J. Bharwada. A widespread opinion prevails among Natives that textiles dyed with *āl* are protected against the depredations of white ants; and if this were so, it would be a powerful argument in favour of its extended use, instead of its discontinuance, but the matter has never been scientifically confirmed. Some years ago the dye was thoroughly investigated by Prof. Hummel and Mr. Perkin of the Yorkshire College, Leeds. They found that the root does not dye in its original condition, but that either the glucosides must first be hydrolysed or that certain acid substances must be removed. The former is effected by boiling with acids or alkalis, or by fermentation. The process of removing the acids consists in washing the powdered root three times, two hours each time, with water. The last steeping may occupy twenty hours. The dye-bath is then charged with the washed root and 1.5 per cent. of its weight of sodium carbonate or 1 per cent. of chalk. The temperature is gradually raised to the boiling-point and the colours cleared with boiling soap solution. [Cf. Forster, *Pl. Esc.*, 1786, 41; Rumphius, *Herb. Gum.

It yields a GUM which is white when it exudes but turns gradually to a mahogany colour. It belongs to the tragacanth or hog-gum series, but owing to its dark colour is of no European commercial value. From the seeds a clear, limpid, almost colourless OIL is easily extracted by pressure. Both this oil and that from *M. aptera*, Juss., are commercially termed Ben Oil, and are highly valued as lubricants by watch-makers. The oil is, however, but seldom made in India and does not form an article of export. Owing to its power of absorbing and retaining odours, it is fairly largely employed by perfumers. The tree flowers in February and produces long, whip-like beans in March and April. Leaves, flowers, pods and even twigs are all cooked as pot-herbs. The immature pod is used in making the drum-stick curry of Europeans. The pod is also made into pickles, and the root has long been known as an efficient substitute for horse-radish. [*Of. Paulus Ægineta* (Adams, transl.), iii., 65; *The Bower Manuscript* (Hoernle, transl.), 1893-7, 84, 103, 108; Acosta, *Tract. de las Drogas*, 1578, 343; Milburn, *Or. The economic information regarding each species cannot be accurately separated, as all possess very similar properties.

White.

. alba, Linn.; the White Mulberry, *tūt*, *tūl*, *chinni*, *satur*, *uppu nute*, etc. A small deciduous tree indigenous in Northern and Western Asia; cultivated in Northern India and Trans-Indus country up to 11,000 feet. It is the chief mulberry used for silk-production in the Panjāb and Kashmir. The fruit is edible, and there are many varieties according to locality. It flowers in February and the fruit ripens in May and June. The wood weighs from 38 to 56 lb. per cubic foot (Gamble), and is employed for building, in making boats, furniture and agricultural implements. [*Of. Bentham, Rev. of Targioni-Tozzetti*, in *Journ. Hort. Soc.*, 1855, ix., 170-1; Dodge, *Useful Fibre Plants of the World*, 1897, 243; Hosie, *Rept. on Prod. of Ssu'ch'uan, China*, 1904, No. 5, 17, 50, 55.]

Fruit Edible.

THE MULBERRY

. *indica*, Linn.; *tút*, *nuni*, *chhota kimbu*, *mekrap*, *singtok*, *karan*, *jo-kul*, *ambor*, *kambili-púch*, *happal-nerali*, *posa*, etc. A moderate-sized deciduous tree of the Lower Himalaya and Sub-Himalayan tract from Kashmir to Sikkim, ascending the hills to 7,000 feet; Shan hills of Burma at 4,000 feet; cultivated elsewhere in Northern India and the Nilgiris for purposes of sericulture.

In the silk districts of India proper, the mulberry is reared on what is called the bush system, not the tree system that prevails, for the most part, in Europe. It can apparently be grown on any description of high and well-drained land, but it is said to do better on loam than on stiff clay or on sandy soil. Deep cultivation is absolutely necessary, and in some parts of the country, as, for example, in Bogra in Eastern Bengal, where the mulberry is attempted on land annually inundated, the method prevails of raising the land in ridges. Soil is dug out from the sides and thrown on the top of the ridges, the result being the formation of bands of land (upon which the mulberry is raised) 3 to 6 feet wide and 3 to 4 feet above the rice-growing intervening strips. The following is the system pursued in the Bardwán district of Bengal, which may be accepted as representative of that which prevails through the chief districts of Indian mulberry silk-production. When the rains are over, the land is dug to a depth of about 18 inches, from September 15 to November 15. The field is then ploughed twice, levelled and well watered. Propagation takes place from November 15 to December 15, and is made by cuttings set in holes 18 inches apart, each hole being 18 inches in diameter and 6 inches deep. When an exhausted crop is cut down, the plants are divided into pieces 9 inches long, the tops and all thin, dry stems being rejected. The cuttings are then tied into bundles. A pit is excavated near a tank, and the bundles of cuttings are sunk in mud at the bottom, to the depth of a few inches. They are kept in that condition for about a month, and watered till the buds have put forth shoots about 2 inches long. When this happens, they are taken out of the mud, planted horizontally in the fields, as above described, one to three in each hole, covered with earth, and watered once a week till they take root. When the plants are about a cubit high, the whole field is flooded, but when they are 2 to 3 cubits high, irrigation is necessary only once every 1½ or 2 months. In February-March the plants are fit for leaf-plucking. After the May plucking the field should be hoed, and at the end of June and beginning of July weeds should be smothered by turning up the soil. Before the commencement of leaf-plucking in the second year, the field is top-dressed with pond mud, about 400 maunds per *bigha*. The plants are thus treated once every 3 years and are kept up for 10 or 12 years, when they are cut down to the ground. By hoeing and manuring, however, new plants spring from the stools, and these may be kept growing for a further period of 5 years, when a new field is regarded as necessary.

The fruit is edible, and employed in Kashmir in the distillation of spirit; fruit, bark and root are all medicinal. The wood is very similar to that of *M. alba*, and is used in Assam for boat oars and furniture. Stein mentions that he found a saddle made of mulberry-wood in ruins explored by him in Khotan, of the third century (see *Paper*, p. 863). [*Cf. Marco Polo, Travels* (ed. Yule), i., 378; Buchanan-Hamilton, *Stat. Acc. Dinaj.*, 1833, 210-4; Roxburgh, *Repts. on Cultivation in Manuf. Cotton-wool, Raw Silk, etc.*, E.I.C. O CHU O C IF RU, Linn.; *Blanford, Fa. Br. Ind.* (Mammalia), 552-3; **CERVIDÆ**. The Musk-deer, *kastura*, *mushk*, *raos*, *rous*, *la-lawá*, *rib-jo*, *bena*, *mussuck-naba*, etc.

A solitary animal, more than two being seldom found together. It frequents wooded slopes, often very steep. Is very active and sure-footed and progresses by a series of bounds. Is by no means shy, where it has not been much hunted. Is of nocturnal habit and not much larger than a greyhound. Of all ruminants it is reported to eat the least, and although no connection can be traced between the nature of the food and the production of musk, those reared in forest-clad mountains are better than those et with in open

usk-
deer.

Distribution.	rocky country. Occurs on the Himalaya west to Gilgit and east to Sikkim, usually at altitudes of 8,000 to 12,000 feet, and is also met with in Tibet and Central Asia as far as Siberia. The rutting season is in January, the period of gestation about 160 days, a single young one being usually produced.
Follicle.	Musk is the contents of the abdominal gland—the præputial follicle. Within is a secretion that looks like coagulated blood, has a greasy touch and a strong penetrating odour. It is only developed in the rutting season, and as sold is a brown, soft mass possessed of the well-known odour. An ounce is about the average produce of one animal. Good and pure pods fetch from Rs. 10 to Rs. 15 according to size, but they are often much adulterated with blood and other material. Musk-deer are snared or shot to secure the “musk-pods,” but the flesh is said to be well-flavoured and not at all tainted, as might have been expected, with the penetrating odour of the musk. The males smell of it, but the females never do so.
Yield.	
Price.	
Trade Qualities.	There are recognised in trade three chief grades, viz., (1) the Cabardion or Russian musk; (2) Assam musk (which includes all grades of Indian musk); and (3) Tonquin or Chinese Musk. The Assam and Tibetan musks reach Europe <i>via</i> Calcutta. When dried within the follicle, it bears the name of “Musk-pods”; when scraped out and sold in granular form it is called “Grain Musk.” It is shipped in bags enclosed in wooden or tin-lined chests that contain about 200 pods. In the <i>Dictionary</i> will be found an interesting note on the Bashahr Musk, contributed by Mr. G. G. Miniken. The Himalayan Musk has been known from ancient times and Baber in 1519 refers to it, but within the past decade or so the demand for the Indian article seems to have been declining.
Musk-pods.	
Grain Musk.	
Trade.	The following were the exports to foreign countries:—In 1899–1900, 611 oz., valued at Rs. 11,900; in 1900–1, 647 oz., valued at Rs. 18,873; in 1901–2, 309 oz., valued at Rs. 13,320; in 1902–3, 44 oz., valued at Rs. 1,500; in 1903–4, 53 oz., valued at Rs. 2,425; in 1904–5, exports <i>nil</i> ; in 1905–6, 223 oz., valued at Rs. 11,180; and in 1906–7, 668 oz., valued at Rs. 14,500. <i>Capital</i> (Oct. 20, 1904) gives an instructive account of the traffic in this substance and exhibits the official statistics of imports into Bengal from Tibet and Bhutan for 16 years prior to that date. The Bhutan had preserved a mean valuation of Rs. 15,000, while the Tibetan had fluctuated from a valuation of Rs. 3,343 to Rs. 1,27,144. “The official valuation of the Tibetan musk last year was Rs. 40 per oz. and that of Bhutan Rs. 32. The price of the Tonquin musk in England has been high as 119s. an oz. and as low as 45s. Ten years ago the price was from 90s. to 95s. the oz. The latest quotations in the London market for genuine grain musk of good quality is 72s. 6d. to 75s. per ounce.” [<i>Cf.</i> Marco Polo, <i>Travels</i> (ed. Yule), ii., 35; Baber, <i>Memoirs</i> (Leyden and Erskine, transl.), 313; Barbosa, <i>Coasts E. Africa and Malabar</i> (ed. Hakl. Soc.), 186–7; Terry, <i>Voy. E. Tonquin.	
Substitutes.	Musk Substitutes. —The term “Musk” is in common usage applied in compound names to a number of products of both animal and vegetable character, possessed more or less of the scent of the true perfume. Amongst these may be mentioned the musk-rat (or shrew); the musk-plant (<i>Mimulus moschatus</i>); and the <i>Abelmoschus</i> of India (<i>Hibiscus Abelmoschus</i>). The last mentioned is the only substitute that has so far attracted serious attention, but the experiments in its cultivation on a commercial scale cannot be regarded as having proved successful.

A genus of tree-like herbs with thick stems largely composed of the convolute leaf-sheaths. It contains some 40 species, several of which are often considered as mere cultivated varieties.

. **ie tu**, *Linn.*; The Banana, *kéla*, *kach-kula*, *kantali-kela*, *múz*, *vazhaip*, *pazham*, *anati*, *ariti*, *bálé*, *vasha*, *ya khaing*, etc. A perennial herb, 8 to 15 feet in height, indigenous in the hills of Bihar, the Eastern Himalaya and the mountains of Assam, Manipur and Burma, ascending to 4,000 feet; cultivated throughout India and the tropics. By some writers the Plantain is considered a distinct species, and placed under the name *M. paradisiaca*, but by most authorities it is simply a cultivated variety of *M. sapientum*. According to Schumann, both should be placed under *M. paradisiaca*.

Plantain versus
Banana.

J. G. Baker, in the *Flora of British India*, gives ten different forms of this plant. The more important of these from the Indian standpoint are:—

Cultivated
Forms.

. **acca**, *Horan.*, *Prod. Monog. Scit.*, 1862, 41. Distinguished by the pale green leaves and stem, white pruinose below, the petiole having a broad red border and the fruit being pale yellow. Cameron adds that the tip and stout stalk remain of a bright green, while the fruit is still firm on the bunch when fully ripe. Cameron also suggests that this is the *Dacca* or *Dacæ-Martaban*; is doubtless the *dhakkai* described by Liotard as abundant in Eastern Bengal.

Dacca.

. **Cha pa**, *Hort.* Stem and mid-rib of the leaf red, fruit pale straw-coloured, about 6 inches long. Cameron makes two forms. These are the *Champa*—the finest of all the plantains, but not fit to be eaten till it can be removed from the bunch without the slightest effort: and the *Chini-Champa*, which differs only from the preceding in being much smaller (in fact, not much larger than the thumb). These two are the plantains most generally seen in Calcutta.

Champa:
Calcutta.

. **sikki ensis**, *Kurz.* A wild form.

. **paradisiaca**, *Linn.* Fruit large, long and firm—the field plant of India generally; is eaten only after having been cooked. This is the plantain of Cameron, while *M. Dacca* and *M. Champa* above, with the Bombay red fruit below, would be the Bananas of India. Under this form should be included the *kuntela* and *kach-kela*, the large coarse fruits eaten by the poorer classes throughout India.

Plantain.

. **corniculata** (*Rumphius*), *Kurz*, a form closely resembling *M. paradisiaca*, and its representative to a large extent in Western and Southern India.

. **textilis**, *Née* (see below).

. **arakanensis**, *Ripley*. In the *Flora of British India* this is simply mentioned as a fibre-yielding form, but Capt. Ripley sent to the Agri-Horticultural Society of India (in 1857) 19 forms of Arakan plantains, each possessing special properties of its own, some having red, others pale yellow, and still others dull white fruits. The one which he specially designated *M. arakanensis* yields, he says, both a fine fruit and a useful fibre. One of these Arakan plantains—the Royal Plantain—he further observes, bears fruits 15 inches long. The most characteristic plantain of Burma much resembles the Bombay red plantain, which Cameron calls:—

Arakan.

. **rubra**, *Firminger* (*non Wall.*); Baker, *Ann. Bot.*, vii., 221; *ram-kela* or Red Plantain. This is a remarkably fine fruit; in flavour and buttery consistency recalls the *Dacca* plantain. The plant is unmistakable at a glance, it has the stem and leaf-stalks and mid-ribs of a dull red colour, as also the flowers. The fruit is about 7 inches long and rather thin, is at first of a very dark red colour, but ripens into a yellowish red. Though not very common in India as a whole, it is the characteristic better-class plantain of Bombay. Hence the plantains of Calcutta and Bombay are widely different, both in appearance and flavour.

History.—The name "Banana" is very seldom used by the English in India, though it is universal in the fruit-shops of England. In India all kinds are indiscriminately called plantains. But neither name would appear to be originally Indian. The plant grew in Palestine before the Crusades. Garcia de Orta, 1563 (*Coll.*, xxii.), says the word came from Guinea, and that the Arabs call "these figs" "Musa" or "Amusa," names which of course come from the Sanskrit *mocha*. The origin of the name "Plantain" is perhaps even more obscure. In *Hobson-Jobson* it is said that according to Oviedo (1516), "it or rather *platan*o appears to have been the name under which the fruit was first carried to the W. Indies." But according to Oviedo the plant was improperly so called, as it was quite another thing from the *platanus* described by Pliny. Early mediæval travellers generally call the fruit either "Fig of Paradise" or "Fig of India," and in the West Indies to-day the common small plantains are called figs. Ligon (*Hist. Barbados*, 1657, 80-2) is perhaps the first author who attempted to describe and figure the two plants, calling them by the names of banana and plantain. [*Cf. Joret, Les Pl. dans L'Antiq.*, etc., 1904, ii., 301-2.]

Cultivation.—The plantain is cultivated very nearly throughout India, except in the extreme north-west and from sea-level up to 5,000 or 6,000 feet in altitude. In certain localities large gardens (of many acres) are planted almost exclusively with the fruit, and the produce is systematically sent to Calcutta, Bombay and other large towns. More frequently it is cultivated merely in small patches around the homesteads and for home consumption. Throughout the plains of India the plantain is extensively produced, especially along the banks of rivers, canals and tanks. Many distinct races exist and these may be grouped under two heads, those grown for their ripe and those for their half-ripe fruits; the latter being used as green vegetables. The vegetable forms are known by the general name of *kach-kela* and are raised on inferior lands as field crops. The fruit forms require more careful cultivation and on garden soils. *Kach-kela* plantains will grow on almost any soil except stiff clay and barren sand, but both field and garden varieties do best on newly raised earth, as, for example, on embankments. On laying out a garden it is customary to excavate a tank and to plant as a first crop, on the new soil spread on the surface around, a quantity of plantains.

Propagation is entirely by rooted cuttings or portions secured from old stools. These may be deposited in holes made within fields of standing *âus* paddy, *kachu* (*Colocasia antiquorum*), *began* (*Solanum Melongena*) or turmeric (*Curcuma longa*). The pits or holes are ordinarily 12 to 15 feet apart and the transplanting is usually made in the rainy season (beginning of June to end of July). The pits should be about a cubit deep and manured with cow-dung. When the secondary crop is off the field (April 15 to June 15) the ground is ploughed two or three times. The plantains begin to bear fruit one year after setting, and the ground is then usually devoted to the plantain crop alone. When a sufficient bunch of fruit has set, the pendent extremity of the inflorescence, with its remaining flowers and conspicuous bracts, should be cut away, so that all the available nourishment may go to the formation of fruit. No clump should at one time have more than three suckers at the base. Extra suckers that appear must be removed in June or July and transplanted into fresh ground. When the bunch of fruit has ripened and been cut off, the stem should be severed at the base, so as to make room for the other fruiting stems of the stool. The cost of cultivating 100 trees has been estimated at Rs. 12-12 annas, and from 300 to 600 bunches of fruit may be obtained, which fetch about Rs. 150 per acre per annum.

Of the Madras Presidency it is stated that plantains are grown chiefly

PLANTAIN FIBRE

U A
API TU
Cultivation

on wet lands. The land is thoroughly ploughed and the shoots planted in pits, almost any month, but more especially during the monsoons. Cameron (*For. Trees Mysore and Coorg, etc.*, 323) suggests that planting should be made every two months so as to keep up a succession of fruiting. Irrigation is effected by flooding the soil, and after the water has soaked in for a day, the superfluous water is run off through drains. The land is then hoed once a month, and three months after planting a surface dressing is given of wild indigo and dung. Hoeing is stopped as soon as the flowers appear, but begins again after gathering the crop. The plants last three to four years.

Flooding.

Duration.

Food and Fodder.—Plantains, after mangoes, are the commonest and most highly prized of all Indian FRUITS, while the coarser kinds constitute one of the staple articles of diet in many parts of India and the Malay Peninsula, being mostly cooked before being eaten. It has been proved that the produce from one acre will support a much greater number of people than a similar area under any other crop, and the immense yield may be preserved for an indefinite period by drying the fruit and preparing meal from it. Plantain meal is made by stripping off the husk, slicing the core, drying it in the sun and then reducing it to a powder and finally sifting. It is calculated that the fresh core will give 40 per cent. of meal, and that an acre of average quality will yield over a ton. [*Cf. Bhaduri, Rept. Labor. Ind. Mus. (Indust. Sec.), 1902-3, 26.*]

Food.

Value.

Meal.

In the *Kew Bulletin* of 1894 will be found a complete review of the available information regarding the production and trade in the bananas and plantains of the world. The recent demand has given the West Indies a new and profitable industry. There seems no very good reason why India should not participate in the supply of the finer bananas.

West Indies.

Besides the fruit, other parts of the plant are used as food. The flower-heads of many kinds are cooked, generally in curries, and the inner portion of the stem, called *thor*, is also edible. The shoots and tops of young plants are occasionally used as a vegetable, and are given as fodder to sheep and cattle. The outer sheaths are valued as elephant-fodder, and the root-stock is said to be given to cattle to increase the quantity of milk. [*Cf. Rept. Labor. Ind. Mus., 1900-1, 24.*]

Flowers, Edible.

Fodder.

Industrial Uses.—For long the FIBRE of the plantain has been used by the Natives of India for cordage purposes, mats and coarse paper. It early attracted attention from the fact that it so closely resembled Manila hemp, (the product of *M. textilis*), though it is not so strong as the latter and can never hope to compete with it in the European markets. The special Arakan form might, however, prove a useful substitute for the true Manila hemp, and is worthy of special attention. Moreover, vast numbers of the common plantain stems are available for extraction of the fibre, and as at present these are simply thrown away, efforts have been made in recent years to encourage the extraction of the fibre as an additional source of profit. The rapidly increasing demand for cheap string to be used as "binders" should render this suggestion of interest to both the cultivators of the fruit and the cordage manufacturers. The subject of the wild species of *Musa* as sources of fibre has aroused some attention, and it seems possible that this idea may come to be of value, especially in some portions of Burma. The chief difficulty in the utilisation of plantain stems as sources of fibre or as paper materials is the expense of collecting and carting

Fibre.

Cheap String.

Paper Material.

to the factory. Profitable results are only likely to be attained with large plantations.

Medicine. In MEDICINE, the unripe fruit is considered cooling and astringent. The young leaves are used as a dressing for blisters, burns, etc. The root and stem are reputed to be tonic, antiscorbutic and useful in blood disorders and venereal disease.

**Manila
Hemp.**

. *textili*, Née; *Fl. Br. Ind.*, vi., 263; Manila Hemp. A native of the Philippine Islands and experimentally cultivated in India for its fibre, especially in the Andaman Islands and in the Arakan hills. By the Natives of the Philippines both plant and fibre are called *Abaca*.

**Cultiva-
tion.**
Soils.

It is said that the plant thrives best on soils largely composed of decayed vegetable matter. Hilly land, about 200 to 500 feet elevation, is considered more suitable than low-lying land. The Manila hemp plantations are situated where there is a rich volcanic soil and where the climate is hot and humid with a heavy rainfall. Plantations are usually established by means of suckers put out when about 3 feet high and placed 8 to 9 feet apart. The land is cleaned of weeds twice a year and the first crop is reaped at the end of the second year after planting, though a full crop is not obtained till the fourth year. The stems are ready to be treated for fibre just before the trees begin to flower, when they are cut about a foot from the ground and the leaves removed. Each stem is then stripped into its component layers (or leaf-sheaths). In other words, each leaf-sheath is usually cut lengthwise into three strips about 3 inches wide. The outer leaf-sheaths contain a coarser and stronger fibre than the inner, while the fibre from near the middle is of a fine silky texture.

Plantations.

Yield.
**Separation of
Fibre.**

In preparing the fibre, each strip is taken by hand and drawn between a blunt knife and a smooth board attached to a light frame. This process removes watery particles and pulp. The fibre is then dried in the sun and packed in bales for shipment. The chief characteristics of the fibre are its great strength and extreme lightness. Hence it is eminently suited for rope-making. The waste materials and worn-out ropes afford the much-prized Manila-paper. The importance of the Manila fibre in the commerce of the world may be judged of from the fact that in official statistics it is stated the annual production comes to close on 1,000,000 bales, which go to the United States and Great Britain in about equal proportions. In the trade returns of Great Britain, the Philippine and Ladrone Islands are shown to have supplied hemp on an average (1902-6) of over 50,000 tons, valued at fully 1½ millions of pounds sterling. It is stated that Manila rules the market of white fibres and that it has ranged from £14 to £60 a ton, the average price being from £25 to £30 a ton.

Plants*, 1903, ii., 894-5; Hooper, *Agri. Ledg.*, 1907, No. 3; MYRISTICACEÆ. A genus of evergreen aromatic trees. According to Sir George King, 22 species are indigenous to India and one cultivated.

. *canarica*, *Bedd.*; Talbot, *List Trees, etc.*, 165; Gamble, *Man. Ind. Timbs.*, 556; the *pindi*. This is discussed by Hooper (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1906-7, 9) under the name *pundi-kai*. The seeds are made into candles and they contain half their weight of fat, which melts at 39° C. It saponifies with great facility, yielding 92 per cent. of crystalline acids, melting at 41° C. The fat consists largely of *myristicin*. In another report (*l.c.* 1903-4, 31) Hooper refers to the juice of *M. gibbosa*, *Hook. f. & T.*, which he describes as the Assam nutmeg. The ferment of the fluid he speak of as resembling that of kino.

. *malabarica*, *Lamk.*; *kánagi*, *shola vengai*, *pathiri*. A large tree of the western coast from the Konkan southwards in evergreen forests. Like the previous species, the seed yields a yellowish oil when bruised or boiled. It is used medicinally and for illumination (Hooper, *l.c.*, 1906-7, 9). The fruit appears to have been used for adulterating the nutmegs and mace of *M. fragrans*. The wood is moderately hard and used in building. [*Cf. Pharmacog. Ind.*, 1893, iii., 197.]

. *agrans*, *Houtt.*; Nutmeg, and Mace; *jaiphal* (nutmeg), *jati*, *jatri* (mace). A bushy, evergreen tree, native of the Moluccas. Cultivated in India but not to a great extent. It has succeeded best at the Botanic Garden of Barliyar, in the Conoor Valley at the eastern side of the Nilgiri hills. The fruit yields the valuable spices "nutmeg" and "mace," the former being the hard ruminated albumen and the latter the aril (*lavanga*, see p. 313).

Cultivation.—According to Nicholls (*Textbook Trop. Agri.*, 1892, 178-84), the best soil for the nutmeg-tree is a deep, rich loam, with good drainage. It will not thrive on sandy soils, and stagnant water about the roots soon kills it. The climate must be hot and moist with an annual rainfall of 60 to 70 inches. Plants are raised from fresh seeds, sown in nursery beds, sheltered from sun and wind. They require to be watered every day in dry weather. When 2 to 3 feet high they are transplanted at distances of 25 to 30 feet apart. The young trees must be shaded and well watered, and the land constantly weeded. Should dry weather come, the ground around the stems is improved by being mulched with straw, leaves or stable litter. All parasitic or epiphytic plants on stem or branches should be at once removed. When the trees flower the sexes must be determined and about one male left to every eight or ten females. The males should be on the windward side, so that pollen may be carried to the female plants. The trees commence to bear about the seventh year, and the produce increases till about the fifteenth.

Manufactures.—The fruit is picked up every morning after it has fallen from the tree. From 1,500 to 2,000 nuts should be obtained from each tree in full bearing. The mace is stripped off and the nuts dried in sheds in trays raised above smouldering fires. When dry the shells are broken with mallets, and the nuts rubbed with lime to prevent attack from worms and then packed in tight cases for export. The mace, after being stripped off, is spread on mats or trays to dry, when it turns yellowish brown and becomes the mace of commerce.

Oil.—Nutmeg yields an essential and a fixed oil, while mace also contains a peculiar essential oil. The fixed oil, "nutmeg butter," is obtained by expression, the powdered nuts being steamed and pressed while hot. It occurs in blocks of a yellow colour. The essential oil is obtained by distillation, and is white in colour, with the odour of nutmeg. The essential oils of both nutmeg and mace are largely used in perfumery.

Medicine.

In **MEDICINE**, nutmeg is an aromatic stimulant, carminative, and in large doses narcotic. The widespread use of both nutmeg and mace in European cookery is well known.

Trade.
Exports.

Trade.—As regards trade, the **EXPORTS** of Indian merchandise for the six years 1901-7 were as follows:—In 1901-2, 170 lb., valued at Rs. 106; in 1902-3, 5,287 lb., valued at Rs. 2,683; in 1903-4, 2,596 lb., valued at Rs. 1,169; in 1904-5, 5,086 lb., valued at Rs. 2,586; in 1905-6, 560 lb., valued at Rs. 194; and in 1906-7, 793 lb., valued at Rs. 691.

Imports.

The **IMPORTS** for the same years were as follows:—In 1901-2, 589,295 lb., valued at Rs. 2,54,259; in 1902-3, 626,871 lb., valued at Rs. 2,32,325; in 1903-4, 571,118 lb., valued at Rs. 2,17,870; in 1904-5, 854,818 lb., valued at Rs. 3,10,071; in 1905-6, 671,445 lb., valued at Rs. 2,15,137; and in 1906-7, 715,018 lb., valued at Rs. 2,28,453. Almost the whole of the imports come from the Straits Settlements, viz. in 1906-7, 706,366 lb. There is, moreover, a **RE-EXPORT** trade, which shows the following returns:—In 1901-2, 19,130 lb., valued at Rs. 7,940; in 1902-3, 69,975 lb., valued at Rs. 44,549; in 1903-4, 16,050 lb., valued at Rs. 9,667; in 1904-5, 21,677 lb., valued at Rs. 10,026; in 1905-6, 15,217 lb., valued at Rs. 8,392; and in 1906-7, 21,287 lb., valued at Rs. 10,542. The United Kingdom receives the largest share of the re-exports, while British East Africa, Aden, Turkey-in-Asia, and in some years France and Egypt, also take considerable quantities.

Re-exports.

[*Cf. Varthema, Travels*, 1510 (ed. Hakl. Soc.), 241, 243; *Garcia de Orta*, 1563, *Coll.*, xxxii.; *Acosta, Tract. de las Drogas*, 1578, 36; *Linschoten, Voy. E. Ind.*, 1598 (ed. Hakl. D.E.P.,
v., 33 -41.
pikenard.

NARDO TAC Y JATA AN I, DC.; *Fl. Br. Ind.*, iii., 211; **VALERIANACEÆ**. Spikenard, *jatamánsi*, *bálu-char*, *behh-kurphus*, *haswa*, *pampe*, *mási*, *bhutt-jatt*, *bala-charea*, etc. A perennial herb of the alpine Himalaya, which extends eastwards from Garhwal and ascends to 17,000 feet in Sikkim.

Perfume.

Through the researches of Sir W. Jones (*As. Res.*, 1790, ii., 405-17) this perfume was first identified with the spikenard of the ancients. In *The Bower Manuscript* (Hoernle, transl.) numerous references are made to *mamsi* and *nalada*, which the translator regards as the present plant. The manuscript in question dates from the 8th century and was found at Kucha in Khotan. *Garcia de Orta* (*Coll.*, l.) gives an account of the spikenard, but as he speaks of it as procured from Mandu, Chitor and parts of Bengal bordering the Ganges, it seems likely that he confused *Cymbopogon* with *Nardostachys*. The drug consists of a portion of the rhizome, about as thick as the little finger, surmounted by a bundle of reddish-brown fibres, the remains of the radical leaves. It is aromatic and bitter, and yields on distillation an essential oil. In India it is largely used as an aromatic adjunct in the preparation of medicinal oils, and is popularly believed to increase the growth and blackness of the hair. [*Cf. Pliny, Nat. Hist.*, bk. xii., ch. xii. (Holland, transl.), 364; *Paulus Aegineta* (Adams transl.), iii., 264; *Amatus, Comment. on Dioscorides*, 1558, 12-5; *Acosta, Tract. de las Drogas*, 1578, 173-81; *Celsius, Hierobot.*, 1747, ii., 1-11; *Roxburgh, As. Essential Oil.

N P LIUM LIT-CHI, *Camb.*; *Fl. Br. Ind.*, i., 687; Gamble, *D. .P.*,
Man. Ind. Timbs., 1902, 197; Talbot, *List Trees, etc.*, 1902, 109; Cooke, *v.*, 346—
Fl. Pres. Bomb., 1903, i., 268; SAPINDACEÆ. The Litchi, *litchi*, *litchi*,
kyetmauk. A handsome evergreen tree, introduced from South China
and now largely cultivated in Northern India for its delicious FRUIT. *Lit-chi.*

The tree grows well in all parts of India, but in the north-west is apt to be killed by cold. It prefers a damp climate and abundance of water. The finest quality of fruit has hitherto been produced in Bengal and Assam, more especially the latter province, but fine fruit is also obtainable in Lucknow and in Saharanpur. It may be propagated by seed, but the surest way to obtain good fruit is to propagate by *gûti*, about the end of May. For this method of propagation the reader should consult an article by Masters (*Agri.-Hort. Soc. Trans.*, 1839, iii., 2; vi., 18) quoted by Firminger (*l.c.* 99). The *gûti* made in May will be ready for removing and potting off by the commencement of the cold weather, and may be planted out in the following rainy season. The fruit is nearly round, about an inch and a half in diameter. The edible portion is the semi-transparent pulp or aril which covers the seed. The Chinese dry the fruit, which thus becomes blackish, and in this state it may be seen in London fruit shops, but it is incomparable with the fresh fruit. [*Cf.* Boym, *Fl. Sin.*, 1656, D.; Sonnerat, *Voy. aux Indes*, 1782, iii., 255-8; Bretschneider, *Hist. Europ. Bot. Disc. in China* (quoting Mendoza, 1585), 1898, 11 and (quoting Trigault, 1615) 10-1; Woodrow, *Gard. in Ind.*, 1903, 238; Firminger, *Man. Gard. Ind.* (ed. Cameron), 1904, 265.]

1906; SOLANACEÆ. *Tobacco.*

Prof. Comes of Naples has described some 41 species of *Nicotiana*. The majority are natives of the New World, though a few are met with in the Philippine Islands, Australia and New Caledonia, etc. Only two, or perhaps three, can be regarded as affording the commercial products TOBACCO and SNUFF, but under each of these Comes has assorted numerous varieties and races, some of which possess special properties, and would seem to constitute the trade qualities famed throughout the world. The following are some of the chief forms, and the countries with which these are mainly associated:—

pecies
and
Varieties.

N. T b eu, *Linn.*; *Fl. Br. Ind.*, iv., 245; Comes, *Monog.*, *l.c.* 7-19; *D. .P.*,
also *Della Razze, etc.*, 1-222; Sadebeck, *Kulturgew. der Deut. Kolon.*, *v.*, 353.
1899, 206; Wiesner, *Die Rohst. des Pflanzenr.*, 1903, 613. A native of tropical
America, which Comes views as embracing some six varieties as follows:—

Var. fruticosa, *Hook. f.*, *Bot. Mag.*, 1876, t. 6207; Comes, *l.c.* tt. i., iii.
The narrow-leaved Shrubby Tobacco. A native of Mexico and Brazil. Appears
to be the plant described by some of the older authors—*e.g.* the *herba sancta*
minor of Lobel, and the *Nicotiana minor angustifolium* of Bauhin. According
to Comes, the following are some of the races of this plant—Carabobo, China,
Nepal, Doniak, Singapore and the South Indian.

South Indian.

Var. lancifolia, *Comes, l.c.* tt. i., iv; Heuzé, *Les Pl. Indust.*, 1895, iv., 18.
A native of South America. In India it would appear to be occasionally culti-
vated on the hills, as for example in Kashmir, Nilgiri hills, etc., and in the Philip-
pine Islands (Manilla). Comes mentions, as races of this pl t, Domingo, Kentucky
Burley, Cattaro, etc.

Kashmir.

NICOTIANA

U TICA

pecies and Varieties

SPECIES AND VARIETIES OF TOBACCO

Virginian
Broad-leaf.

Var. virginica, *Comes*, *L.c.* tt. i., v.; also *Della Razze*, etc., 121-5; *Anastasia*, *L.c.* 106-16. This, *Comes* thinks, came originally from the region of the Orinoco and was introduced by the English colonists into Virginia, where, under cultivation, it gave origin to some of the most highly valued forms of tobacco usually grouped under pale and dark-coloured leaf. Among this may be mentioned Big Orinoco, or Virginia Broad-leaf, Yellow Orinoco, Blue Pryor, Yellow Mammoth Golden-leaf, etc.

Brazilian.

Var. brasiliensis, *Comes*, *L.c.* tt. i., vi.; also *Della Razze*, etc., 79-119; *Anastasia*, *L.c.* 101-5. This is the Broad-leaved Tobacco, known in Brazil by the name *petum* or *petun*. A native of Brazil, Guinea, Venezuela and Bolivia. According to *Comes* was introduced into France by Thevet in 1556, and thence to Europe generally. Is the stock from which the so-called indigenous tobacco of Europe has been derived, and is valued on account of the thickness of the leaf rendering it suitable for the manufacture of snuff. The following special races may be mentioned:—Brazil, Bahia, Paraguay, Pernambuco, Florida, Maryland, Ohio, etc.

Havana and
Manilla.

Var. havanensis, *Comes*, *L.c.* tt. i., vii.; also *Della Razze*, etc., 153-97; *Anastasia*, *L.c.* 97-105. Indigenous to the valleys of Mexico. It was conveyed thence by the Spaniards to the island of Cuba, is the plant most highly valued as Havana tobacco, and known by many trade names such as Havana Seed-leaf, Cuban Seed-leaf, etc. This plant is accordingly most largely selected for the improvement of other stocks, and it would appear to be the chief source of the so-called Java and Sumatra tobaccos. The following are some of the chief races mentioned by *Comes*:—Seed-leaf, Connecticut, Pennsylvania, Ohio, Maryland, Wilson's Hybrid, Zimmer's Spanish, Mexican, Manilla, Deli-Tabak, etc. [*Cf.* Shamel, *Imp. Tob. by Breeding and Selection*, etc., in *U.S. Yearbook*, 1904, 435-52; 1906, 387-404.]

Bengal.

Var. acrophylla, *Schrank*: *Comes*, *L.c.* tt. i., viii.; also *Della Razze*, etc., 199-22; *N. Tabacum*, var. *purpurea*, *Anastasia*, *L.c.* 1906, 43-96. A native of Mexico and introduced into many countries—India, Persia, Egypt, Porto Rico, Peru, etc. This appears to yield much of the Maryland tobaccos of commerce. The flowers are usually of a deep purple colour and the leaves exceptionally large. The following are some of the special races mentioned by *Comes*:—Cuban, Varinas, Venezuela, Makala, Salomiki, Argos, etc.

D. P.,
v., 35.

N. ru tic, *Linn.*; *Heuzé*, *L. Pl. Indust.*, 1895, iv., 19; *Sadebeck*, *L.c.* 220; *Wiesner*, *L.c.* 614. This is the *Nicotiana minor* of some of the older authors, and is at once distinguished by its being a smaller plant with almost orbicular-stalked, leathery leaves and pale-greenish white flowers, with the limb of corolla imperfectly developed. It is commonly known as Turkish or East Indian Tobacco. *Comes* regards it as a native of Mexico and Texas. In the former it is known as *picietl* or *pycietl*, and he is of opinion that this was the plant introduced into France by Jean Nicot (after whom the genus was subsequently named). It was cultivated in America before the arrival of Columbus. *Comes* places under it the following varieties:—

Turkish.

Var. texana, *Comes*, *L.c.* tt. ii., ix. A native of Mexico and the plant seen by Nicot under cultivation in Portugal in 1560, the seed of which was sent to Queen Catherine of Medicis.

Var. jaicensis, *Comes*, *L.c.* tt. ii., x. A form met with under cultivation in Jamaica, Guatemala and Mexico, but doubtfully distinct from the preceding.

Snuff
Tobacco.

Var. bras a, *Schrank*: *Comes*, *L.c.* tt. ii., xi. Habitat, Brazil. This is the tobacco which the Brazilians call *fumo-crespo*. It is often used in the manufacture of snuff.

Var. asiatica, *Schrank*: *Comes*, *L.c.* tt. ii., xii. This is the so-called Syrian tobacco, but is also grown in Arabia, Persia and Abyssinia. It came, however, from America and is sometimes designated as the common or English tobacco, and when made into snuff is held to be superior to most other grades, though in many trade samples it has been flavoured with aromatic herbs.

Var. h illis, *Schrank*: *Comes*, *L.c.* tt. ii., xiii. Extensively cultivated for the manufacture of snuff, and in Germany is regarded as superior to the product of *var. brasilia*.

Var. scabra, *Comes, l.c. tt. ii., xiv.* A native of South America. Hardly ever used commercially because of its disagreeable odour.

N. 1 t, *Lk. et O.; N. persica, Lindl., Bot. Reg., 1833, xix., t. 1592; Riach, Sheeraz Tobacco, Trans. Hort. Soc., 1835, i., 205-7.* A native of Brazil and cultivated in gardens in Europe, Persia, etc. At one time it was thought that this plant was the source of the *tumbeki* of Persia. In the *Kew Bulletin* (1891, 77-84) full particulars will be found, the final conclusion of which appears to be that the merits of the *tumbeki* leaf, like that of most other special tobaccos, proceed from the climate and soil, together with the methods of cultivation and curing, more than from specific differences. Comes seems, however, to think that *N. alata* is the source of the Persian leaf, while the numerous writers quoted in the *Kew Bulletin* regard it as derived from the ordinary *N. Tabacum*. *Tumbeki.*

N. plu b i ifoli, *Viv.; Fl. Br. Ind., iv., 246; Comes, l.c. 45.* This is believed to be a native of Mexico and the West Indies. In India it has become completely naturalised, especially on sandy islands within the rivers and in damp situations by the roadsides. It does not appear to be put to any economic purpose. It is not mentioned in Roxburgh's *Flora Indica*, consequently its introduction may date subsequent to 1832.

To conclude this brief statement of the species, varieties and races of tobacco, it may be pointed out that Shamel and Cobey (*Varieties of Tob.*, 1905-6, *U.S. Dept. Agri., Bureau Pl. Indust., No. 91*) give the following classification according to uses :— Industrial Grades.

1. *Cigar-wrapper Tobaccos*—Sumatra, Connecticut, Havana and Connecticut Broad-leaf, etc.
2. *Cigar-filler Tobaccos*—Cuban, Zimmer's Spanish, Little Dutch, etc.
3. *Pipe Tobaccos*—North Carolina, Bright Yellow, Maryland Smoking, etc.
4. *Plug Tobaccos*—White Burley, Orinoco, Yellow Mammoth, Virginia Blue Pryor, White Stem, etc.

Tobacco breeding, Shamel and Cobey have shown (*U.S. Dept. Agri., Bureau Pl. Indust., 1907, No. 96*) is of necessity a subject of the greatest possible interest and value.

istory.—The practice of tobacco-smoking was unknown in Europe and Asia prior to the discovery of America in 1492. It has since been ascertained that the knowledge of the properties of tobacco was very ancient and widespread in the American Continent and Islands. Some difference of opinion prevails as to the locality where tobacco-smoking was first witnessed by Columbus and his associates. By some authorities Cuba is mentioned, by others San Salvador. The plant and the habit of smoking were found by Cortes in the very heart of Mexico. The Spaniards witnessed tobacco-chewing in 1502 on the coast of South America. Monardes published, in 1517, an account of tobacco in which he says that it was known to the Indians (American) by the name *pietl*. In 1518 Fernando Cortez occupied the island of Tobago, and found the plant being there cultivated. About the same time the prepared leaves were brought by Oviedo from San Domingo to Spain. In 1531 the Spaniards commenced the cultivation of tobacco in S Domingo, employing for the purpose African slave labour. Oviedo described a smoking-pipe (*Hist. Gen. de las Indias*, 1535). In 1539 Hernandez brought seed to Europe. Jean Nicot, French Ambassador, saw the plant cultivated in Portugal, and in 1560 sent seed of it to Catherine of Medicis, from which circumstance the genus obtained its botanical name. In the same year tobacco was conveyed to England by Thomas Hariot; Sir Francis Drake and, subsequently (1570-84), Sir Walter Raleigh and others made tobacco-smoking popular in England, and about the same time cultivation was started in Virginia. In 1596 Ben Jonson, in his *Every Man in his Humour*, represented the arguments for and against tobacco. Antiquity of American Knowledge.
Tobacco-chewing.
Cultivation by Spaniards.

Prohibition.

"Counterblaste."

Prohibited in England.

Baber (Conqueror and Emperor of India) wrote his *Memoirs* with special reference to 1519-25, and while describing all the useful and interesting animals and plants found by him in India, makes no mention of tobacco. So also a little later (1563) Garcia de Orta published in Goa his historic work on the drugs of India, but makes no mention of tobacco. The first direct reference to it, in connection with India, centres around certain Portuguese missionaries at the Court of the Great Mughal. Doubtless to the Portuguese is due the credit of having conveyed both the plant and the knowledge of its properties to India and China. It is said in the *Dara-shikohi* that they had conveyed it to the Deccan as early as 1508. Asad Beg, of date 1605 (Elliot, *Hist. Ind.*, 1875, vi., 165-7), says of Bijapur that he found some tobacco and, "never having seen the like in India I brought some with me and prepared a handsome pipe of jewel work." These he presented to the Emperor Akbar, who attempted to smoke, until he was forbidden by his physician. It would thus seem to have been known in the Deccan for nearly a century before it was carried to the rest of India. On the other hand, Comes affirms that the seed cultivated in India in 1605 had been brought from Brazil. In 1610 tobacco was grown in Ceylon, and in that same year it was introduced into Turkey (George Sandys, *Journey*, 66). In 1614 Floris produced a sketch of a Hindu woman of Masulipatam smoking tobacco. By 1617 smoking had, in fact, become so general in India that the Emperor Jahangir forbade the practice, as also had Shah Abbas of Persia (Elliot, *l.c.* v., 851). Foster, in his work *The English Factories in India* (1906, 64, 92, 109), quotes various letters and invoices of date 1619 which speak of tobacco being sent from India to Red Sea ports. Mandelslo (*Travels*, 1638, in Olearius, *Hist. Muscovy, etc.*, 1662, 74) speaks of the Parsis of Gujarat living peaceably and "sustaining themselves out of the advantage they make of the tobacco-plant and the terry they get out of the palms." Cultivation in Gujarat in 1638 is spoken of as successful. In 1645 the plant was carried to Golconda. Edward Terry (*Voy. E. Ind.*, 1655, 96), speaking of Surat, says that "the tobacco which grows there is doubtless in the plant as good as in any other place of the world, but they know not how to cure and order it, like those in the West Indies." Fryer (*New Acc. E. Ind. and Pers.*, 1672-81, 223, etc.) says, "The Persians smoke tobacco in their most solemn assemblies, and for this purpose are provided with spitting-pots or *pigdans*." Tavernier (*Travels in Ind.* (ed. Ball), 1676, ii., 23) tells us that he found tobacco grown abundantly at Burhanpur, and adds, "In certain years I have known the people to neglect saving it because they had too much, and they allowed half the crop to decay." Ovington (*Voy. to Suratt*, 1689, 428) speaks of the people of Muscat abhorring tobacco and burning all that is brought to their city. Strachan (in *Phil. Trans.*, 1702, xxiii., 1134, (abrid. ed.) iv., 667), gives an account of the cultivation and manufacture of tobacco in Ceylon. He speaks of two forms, one much stronger than the other. The *Bahar-i-Ajam*, 1760 (Blochmann, *Ind. Antiq.*, i., 164), speaks of tobacco coming from Europe to the Dakhim and thence to Upper India during the reign of Akbar Shah—a fact already indicated. Col. Kyd (in his letter in 1786 to the Court of Directors, proposing the formation of the Botanic Gardens, Calcutta) mentioned the improvement of tobacco as one of the subjects that might engage attention. Macpherson (*Hist. Europ. Comm. with Ind.*, 1812) makes only a passing allusion to the tobacco trade of India with France, and Milburn (*Or. Comm.*, 1813) does not even mention the name of the "weed." It is thus a fact beyond dispute that tobacco, less than a hundred years ago, was an article of comparative unimportance in India, whereas to-day its use is all but universal—men, women, and even children smoke—and, moreover, the export traffic has become of the greatest importance to the country. The Sikhs, Wahabis and certain Hindus are, however, prohibited the use of tobacco, though allowed indulgence in hemp and opium to any extent. As in other parts of the world, so in India, tobacco passed through a period of persecution, but its ultimate complete distribution over India is one of the numerous examples of the avidity with which advantageous new crops or new appliances have been absorbed into the agriculture and social customs and even literature of the people of India.

It is a matter of every-day knowledge that King James I. issued his famous "Counterblaste" in 1603, and raised the tax to 6s. 10d. on the pound. King Charles, in 1630, prohibited the cultivation in England and Ireland, where it seems, according to Macpherson, great quantities were still raised. In 1633 the King issued a proclamation to regulate the vendors of tobacco in cities and towns. Pope Urban VIII. prohibited smoking in church. By an Act of 1663 cultivation

BENGAL SYSTEM OF PRODUCTION

in England was again prohibited, and in 1670 Charles II. passed still a further Act, by which imports intended for Ireland had, in the first instance, to be conveyed to England. In 1709 the net consumption of tobacco in England came to 11,260,659 lb. In 1731 Virginia and Maryland were regarded as most valuable acquisitions to Britain because, among other considerations, of the tobacco they produced. An interesting account of the cultivation of tobacco in Virginia in 1676 is given by Mr. Thomas Glover in a paper delivered to the Royal Society (*Phil. Trans.*, June 20, 1676, xi., 623, (abrid. ed.) ii., 301—reprinted, Oxford, 1904). By a special Act of George III. (1780) tobacco cultivation in Ireland was allowed, but not in England nor Scotland; and, lastly, in 1830 William IV. prohibited the Irish cultivation.

Cultivation
in Virginia.

Prohibition in
Ireland.

Prior to the separation of the United States, the British supply of tobacco came almost entirely from Virginia. During the reign of Queen Anne the annual revenue from tobacco was only about £250,000. In 1903 the net imports (that is to say, imports less exports) were valued at £3,136,228, or a total weight of 75,915,759 lb., and the traffic gave a revenue of over 12½ million pounds sterling.

Revenue.

CULTIVATION.

Area.—The crop occupied in 1905–6, 1,018,506 acres in British districts and 24,284 acres in the Native States for which returns are available. But since several important States furnish no returns, it may be accepted as a safe estimate to put the total tobacco area of India at 1,100,000 acres. It would, moreover, seem fairly certain that it has not expanded materially during the past ten years. Of the total, Bengal (including Eastern Bengal and Assam), has fully one-half; Madras a little over 130,000 acres; Burma, Bombay, the United Provinces and the Panjáb have each about 60,000 acres.

Cultiva-
tion.

Indian area.

As a rule there are three distinct persons concerned in the tobacco trade. In Rangpur (of Bengal) the cultivators sell the leaf on the field to up-country traders and curers—*dalals*, as they are called—who own large curing-sheds, at certain convenient intervals, through the chief tobacco-producing localities. The curers next sell it to Burmese dealers, who come and supervise the leaf as it is being cured; they then pack and dispatch it themselves. These three classes are fairly general throughout Bengal, the chief tobacco-growing province of India. Tobacco with the Natives of India is either used up in the crude form or is worked into a paste with several ingredients (to be detailed later on), and in that form smoked. The more elaborate curing of higher-grade leaf is pursued over a comparatively limited area, and to meet the demands of the European rather than the Native population. Bengal, the chief growing province, takes practically no share in the higher-grade manufacture. The crudely manufactured leaf (in trade returned as “unmanufactured tobacco”) is exported to Burma or to foreign countries, and in these is worked up into special grades of smoking-tobacco, cigars, etc. In South India (and within comparatively recent years) a new trade has arisen in the manufacture of cigars for the European consumer, both within India and throughout the East generally. Indian cigars have, moreover, found their way to Europe, and the traffic in them is yearly increasing. In the whole of India there are nominally, say, 25 curing farms and factories that give employment to 2,150 persons, but this must be regarded as over and above the large number of persons already indicated as concerned in the cultivation and crude manufacture of the Native article. [*Cf.* Heuzé, *Les Pl. Indust.*, 1895, iv., 24–42.]

Bengal, Eastern Bengal and Assa.—Tobacco is grown for local consumption in almost every district, more especially in Rangpur, Jalpaiguri, Kuch Bihar, Darbhanga, Purnea, the 24-Parganas, Nadia,

Ben al.
Chief Districts.

Areas.

Chittagong, Sylhet and Kamrup, etc. In some of these districts it is, moreover, largely grown for trade and export. In 1905-6 the total area under tobacco in the two provinces of Bengal was 535,525 acres, more than half that of all India, and in Assam 4,911 acres. The districts of Rangpur and Jalpaiguri and the Native State of Kuch Bihar contain the largest areas. In 1904-5 the area in Rangpur was 181,100 acres and in Jalpaiguri 119,300 acres. Two species, *N. Tabacum* and *N. rustica*, are grown. The former is generally called *desi*, and the latter *vilayati* (foreign). *Vilayati* is largely cultivated in Purneah and neighbourhood. So little attention has been paid by writers on this subject that it is said no cultivated races of *vilayati* are known, but that the *desi* has many such, the most important of which is known as *hingli*, produced in parts of Nadia and Jessore.

Irrigation.

One of the most striking features of Rangpur is the extent of tobacco cultivation (*Agri. Ledg.*, 1898, No. 15, 508). Both *N. Tabacum* and *N. rustica* are grown, wherever the soil is a rich, sandy loam with water only a few feet below the surface. Shallow wells are dug all over the tobacco-fields, and during certain stages in growth hand irrigation is daily pursued. The water is thrown from the wells so as not merely to supply moisture to the roots but to wash the dust off the leaves. The agricultural system pursued is of a very high order, and it is not to be wondered at that tobacco should prove so valuable and remunerative a crop, in a country pre-eminently the tobacco area of India. The railway to Jatrapur cuts the district practically in two. In the one half, the northern, with its rich sandy loam, *N. Tabacum* is cultivated; and in the other, the southern, with its lower, damper soil, *N. rustica* prevails. But wherever the red-clay soil appears, tobacco cultivation at once disappears. In Rangpur and Kuch Bihar it is no unusual occurrence to find a single leaf of *N. Tabacum* measuring 3 to 4 feet in length.

The following account of cultivation has been derived mainly from Mukerji and Roy. The crop requires a good soil and heavy manuring. The best kind is a well-drained friable, sandy loam, not too rich in organic matter, but rich in mineral salts, especially those of potassium. It may be grown after jute or Indian corn, but often forms the only crop of the year. If properly manured, it can be grown three or four years on the same ground. The seeds are sown in seed-beds in August or September, and the seedlings transplanted a month later. The soil of the seed-bed is dug and manured with cow-dung and ashes until raised about 6 inches. After the soil has been well pulverised the seed is sown thin and lightly covered with earth. About half an ounce is required to produce plants for one acre.

When the seedlings are about 3 inches high they are fit for transplantation, which takes place from the end of September to the middle of November. The soil must previously be prepared by eight or ten ploughings. Deep cultivation and thorough pulverisation are important, and a liberal manure of rotted cow-dung and ashes is necessary. The seedlings are planted in the evening 3 feet apart. They must be carefully watered the first few days, and irrigation is necessary afterwards at intervals of ten to twenty days. In Rangpur and Jalpaiguri a hand-plough is repeatedly drawn along and across the fields until about the time that the flower-buds appear. Where artificial irrigation is required, regular hoeing is necessary.

MUTURITY OF LEAF

NICOTIA A
Cultivation
United Provinces

Before the plants begin to flower, their buds and lower leaves should be stripped off, and they should be pruned so that only eight or ten leaves are left to each plant. To prevent bleeding, finely powdered earth is sprinkled over the broken parts immediately after pruning. When the leaves begin to turn yellow with brown spots and have a gummy feeling, they are considered mature and ready to cut. The best time for harvesting is morning, as soon as the dew is off the plants. It is better to cut whole plants than to gather the leaves singly, and they should be allowed to lie for some time in the sun before they are conveyed to the drying and fermenting house.

[Cf. O'Connor, *Tobacco in Ind.*, Parl. Paper (c. 982), 1874, 171-83; *Repts. Internal Trade, Beng.*, 1876-7, 85-8, 149; 1879-80, 103-4; 1881-2, 88-9; Sen, *Rept. Agri. Stat. Dacca*, 1889, 44-5; Mukerji, *Handbook Ind. Agri.*, 1901, 417-28; *Admin. Rept. Beng.*, 1901-2, 25-6, 43; Mukerji, *Cult. of Tobacco in Beng.*, in *Proc. Board Agri., Pusa*, Jan. 1906, 92-6; Coventry, *Cult. in Bihar*, 98-9; Roy, *Crops of Beng.*, 1906, 121-35; *Repts. Dept. Land Rec. and Agri., Beng.*; *Exper. Farm Repts., Sibpur.*]

United Provinces.—The crop is not an important one, and its cultivation appears to have been practically stationary for some years. In 1905-6 the total area in Agra was 82,904 acres, and in Oudh 14,566 acres. The districts with the largest area are ordinarily Farukhabad, Aligarh, Balandshahr and Meerut. In no district does the area under tobacco exceed 1 per cent. of the cultivation. Moreland (*Proc. Board Agri., L.c.* 113) gives a concise account of tobacco cultivation. It is grown (1) in heavily manured land close to villages; (2) on the sites of old towns where the soil and well-water are rich in nitrates; (3) rarely in virgin soil in forest tracts. The seed is sown in nurseries and the young plants put out at different times of the year, from July to February, and harvested from February to April. According to Duthie and Fuller (*Field and Garden Crops*, pt. i., 69-74, tt. xvi-xvii.) the seasons of sowing may be grouped into two: (1) sown in July and August, planted out in October, cut in February; (2) sown in November, planted in February, cut in April and May. Tobacco grown in the former season is known as *sāwani*, that grown in the latter as *asārhi*. The rotations are various. Where nitrates abound, the crop may be grown for several years successively on the same land, and where poudrette is available, the commonest rotation is maize, potato, tobacco, all within the year. In preparing the seed-bed the ground is first dug a foot deep and then completely pulverised. Usually from 10 to 30 tons per acre of cow-dung, sheep-dung or poudrette are worked thoroughly into the soil. Crude saltpetre earth may be applied as a top-dressing where the available water is not salt.

After transplanting, the land is kept loose and free from weeds, and all flower-buds and lateral branches or shoots from leaf-axils removed as soon as formed. The plants are usually hand-watered after transplanting, and later, water is run on to the fields as required. From fifteen to twenty waterings are usually necessary. When ripe, the leaves are stripped from the plant, or the whole plant is cut down. The crop is dried in the sun and then stacked under cover. After a period which varies in different localities, the crop is carried home for fermentation.

The cost of cultivating an acre of *sāwani* tobacco is estimated by Duthie and Fuller at Rs. 46-7a. [Cf. Sir E. C. Buck, *Note on Tobacco Cult. and Curing, U. Prov.*, 1787; Nevill, *Dist. Gaz. U. Prov.*]

Central Provinces and Berar.—The area under tobacco in 1905- C. Prov.

Areas.	was 12,194 acres in the Central Provinces, and 14,220 acres in Oudh. The districts with largest areas are usually Raipur 1,105 acres, Bilaspur 995, and Chanda 1,023 acres, in the Central Provinces; Amráoti 5,331 acres, Buldana 3,602, Wun 2,374, and Ellichpur 1,178 acres in Berar. The plant is cultivated in patches near the villages, and the whole produce is consumed locally. The seasons of sowing and reaping vary. In Narsingpur the crop is harvested in October; in other districts the stems are cut usually in February and March.
Seasons.	
Rajputana.	Rajputana and Central India. —In these provinces cultivation is almost confined to the Native States of Gwalior, Jaipur, Bharatpur and Tonk, which in 1905–6 grew respectively 3,590 acres, 2,563 acres, 1,072 acres, and 147 acres. A description by Dr. R. H. Irvine of the famous Bhilsa tobacco, grown in Gwalior, is quoted in the <i>Dictionary</i> . According to O'Connor, tobacco in Central India is raised on high, well-ploughed lands. A second crop is frequently taken from the stems left after the first crop has been gathered.
Second Crop.	
Panjáb.	Panjáb and North-West Frontier. —The area in 1905–6 was 67,594 acres in the Panjáb and 9,666 acres in the North-West Frontier. In the Panjáb the districts with largest areas are usually Jalandhar, 3,756 acres, Sialkot 4,400 acres, Lahore 4,524 acres, Gujrat 3,137 acres, Amritsar 2,890 acres, Gujranwala 3,465 acres, Jhang 2,708 acres; in the North-West Frontier, Peshawar 8,513 acres. The soils generally preferred are garden and manured lands near the villages. Alluvial lands are not considered suitable; in three cases only—namely, parts of the Sialkot, Ludhiana and Rawalpindi districts—are alluvial tracts selected. Irrigation is practised, the plots being watered about once in every four days, and extensive manuring is necessary. Night-soil, sheep- and goat-dung, stable litter and cow-dung, are used, and an admixture of saltpetre is found beneficial. The sowing season in most districts is October and November, but may in some places continue till December and January (Shahpur, Multan, Dera Ghazi Khan) and February (Peshawar, Amritsar, Rawalpindi). Transplanting takes place from January to March, and cutting during May, June and July. The plant is cut to the roots and no second crop taken. [Cf. Purser, <i>Settl. Rept. Jalandhar</i> , 1892, 127–8; <i>Dist. Gaz. Pb.</i> ; <i>Exper. Farm Rept. Lyallpur</i> , 1901–2, 20; Renouf, <i>Tobacco in Pb.</i> , in <i>Proc. Board Agri.</i> , Pusa, Jan. 1906, 115–6.]

Season?	
Crop.	
Kashmir.	Kash ir. —According to Sir W. Lawrence (<i>Valley of Kashmir</i> , 1895, 345–6) tobacco is cultivated in many parts of Kashmir, but chiefly in and around Srinagar and the smaller towns. Cultivation is almost entirely in the hands of the gardener class. The plant yielding the best produce grows in Srinagar, and is known as <i>brewari</i> (<i>N. Tabacum</i> , var. <i>lanceifolia</i>). Another species, <i>chil i</i> (<i>N. rustica</i>), has been introduced from the Panjáb. It is sown in April and picked about the end of August. It requires very rich soil and is irrigated by the dip-wells of the country. The consumption of tobacco in Kashmir is almost entirely in the form of snuff.
Seasons.	
Snuff.	
Bombay.	Bo bay and Sind. —The area in 1905–6 was 64,539 acres in Bombay and 9,048 acres in Sind. The districts with the largest areas are Belgaum 22,856 acres, Kaira 21,276 acres, Satara 4,215 acres, Ahmadabad 3,187 acres, Khandesh 4,364 acres, Broach 2,685 acres, and Hyderabad 4,847 acres. Mollison gives a very full account of the methods pursued. The best kind is grown on deep alluvial lands near the Krishna. Throughout the Kaira
Areas.	
Cultivation.	

district and the adjoining Baroda Territory, where cultivation is extensive, wells with salt water are common, and the water is used for irrigating the tobacco, often with remarkable manurial effects. Wells of special value occur in the neighbourhood of Nadiád (Kaira district) and Pettád (Baroda Territory). For details regarding the manurial value of these salt wells, consult Leather (*Agri. Ledg.*, 1895, No. 14). A free-working and satisfactorily drained soil is best. On such land in Gujarat mild-flavoured tobacco of good quality can be grown. A stronger tobacco with large, coarse leaves grows best on medium clay loams, irrigated with sweet water or salt and sweet combined. In Gujarat, tobacco is rarely rotated with other crops, and it is claimed that the longer the soil is under the crop, the better the produce.

The seed-beds should be prepared on elevated ground and under tree-shade. In villages which grow a large area of tobacco, a piece of ground is usually set apart as a common nursery. The bed should be carefully prepared. The burning on the surface (before the rains set in) of refuse, straw, brushwood or cow-dung improves the mechanical condition, the ashes manure the soil, and the heat kills weeds and insects. After burning (*râbing*), goat manure should be well mixed with the soil, and a fine tilth obtained by hand-digging. The seed (mixed with ashes or fine sand) is sown in July, one ounce to one hundred square feet of seed-bed. The beds require protection from heavy rain, and should at first be lightly watered by hand. Weeds must be removed and the seedlings thinned out. The seedlings are ready for transplantation when they have four leaves and are 3 or 4 inches high. As soon as possible after the harvesting of the previous crop the stems and roots should be grubbed up and burned. The field is ploughed soon after the monsoon has set in, and again frequently between June and August. Twenty-five to thirty cart-loads per acre of well-rotted farm-yard manure should be applied, after the field has been ploughed several times. A better practice is to fold sheep on the fields intended for tobacco. The mud from village tanks is also considered good. Before planting the young seedlings, the field is levelled with the *samâr*, then lined and cross-lined with the *gisle*. A seedling is planted carefully at each angle made by the intersecting lines, and a cloudy afternoon is usually chosen. Frequent watering is required. As soon as the young plants have made a fair start hoeing should begin, and when the flower-buds begin to open they should be removed, and with them two to four of the youngest leaves. About ten to fourteen leaves should be left on each plant. The removal of the flower-buds is followed by the appearance of side branches known as "suckers," and these also should be regularly removed.

On a stiff clay loam soil (*besar*), tobacco is a dry crop, but as a rule in Gujarat it is irrigated more or less according to the kind of tobacco to be manufactured. Irrigation ordinarily begins early in November. Twenty days after the first watering a second is given, and afterwards others at intervals of twelve to sixteen days until the leaves are ripe, usually about the middle of February. In Gujarat the leaves are left on the plant till they are decidedly yellow. Sometimes the whole plant is cut down, but the usual method is to strip off the leaves one by one from the stalk with a small bent sickle.

Poona, Nadiád, etc.; Fletcher, *Cult. Tobacco in Bomb.*, in *Proc. Board Agri., Pusa*, 1906, 116.]

Areas.	Madras. —The area under the crop amounted in 1905–6 to 132,458 acres. The districts with the largest areas are usually Guntur 41,798 acres, Coimbatore 26,884 acres, Godavari 8,143 acres, Vizagapatam 5,037 acres, Madura 8,296 acres, Karnul 6,664 acres, etc. The crop is grown in all districts, though on the Nilgiris and the west coast the area is small.
Cultivation.	Benson (<i>Proc. Board Agri., Pusa</i> , 82–92) gives a very full account of tobacco cultivation in the various districts. In Kistna the crop is grown chiefly in the upland <i>taluks</i> on ordinary black cotton soil. The seed-beds are usually located near shallow pools in which the monsoon rains stand. They are well ploughed and manured. After the first ploughing cattle are penned on the plots, and they are again ploughed once or twice. Village manure, consisting of ashes, earth and dried cow-dung, is then applied at the rate of 50 to 60 loads per acre. After two or three more ploughings the seed is sown broadcast, at the rate of one local seer to 18 cents of land, and pressed in by the hand. At first, watering is frequent, three or four times a day. After twenty days, watering is reduced to once a day, and all unhealthy leaves are picked off daily.
Soils.	
Manure.	
Irrigation.	
Transplanting.	In about two and a half months, when the plants are 8 to 9 inches high, they are trimmed and lateral shoots, if any, removed, and fifteen days later are pulled up and made into bundles for planting. The preparation of the land for the crop commences about July. Before this, village manure and tank silt are applied, and cattle, sheep or goats penned on it after the first ploughing. The land is ploughed seven to ten times, then twice with the <i>gorru</i> , and afterwards marked off into squares. The young plants are placed in holes filled with water at the corner of the squares, and the earth gathered round them. They are watered for two days in the morning, then for two days in the evening, but are afterwards left to themselves. The crop is topped when 2½ feet high and suckered twenty days later, and about ten days later still is ready for harvest, in February or March. No second growth occurs, and the stems are cut down and used for fuel.
Seasons.	
Irrigation.	
Pruning.	
Harvest.	
Snuff.	In cultivating tobacco for the manufacture of snuff, the crop is never irrigated from wells, but the plants are grown by the aid of rain alone. Again, if the tobacco is for chewing, watering is withheld four or five days before harvest. The chief centres for snuff tobacco are Trichangode, Rasipuram and Uttankarai <i>taluks</i> in Salem district.

[*Öf. Schiffmayer, Tobacco and Its Cult., Saidapet Exper. Farm*, 1878; *Planting and Manuf. of Tobacco in Southern Ind.*, Madras, 1880; Shortt, *Man. Ind. Seasons.	
Transplanting.	

sheep. They are placed in holes 18 inches apart and filled in with a mixture of red earth, sand and dung. About a month and a half after being set out they are topped, six or seven leaves only being allowed to remain, and the suckers are removed. They are ripe in November and January and cut down to within 4 or 5 inches of the ground. The stems are then split lengthwise, each portion carrying three or four leaves. [Cf. Rice, *Mysore Gaz.*, 1897, i., 126-8.]

Pruning.

ur. a.—The total area in 1905-6 amounted to 49,205 acres in Lower Burma, 26,560 acres in Upper Burma. In Lower Burma the largest areas occur in Henzada, 12,849 acres; Thayetmyo, 6,627 acres; Tharawadi, 5,601 acres; Prome, 3,772 acres; and Kyaukpadaung, 3,525 acres; in Upper Burma, Pakókku, 5,530 acres; Mandalay, 4,393 acres; Minbu, 2,646 acres; Sagaing, 4,156 acres; and Myingyan, 3,944 acres.

Burma.

Areas.

Mackenna (*Settl. Rept. Henzada*, 1901, 50-1) states that the bulk of the crop is grown on low lands annually flooded. A high-land portion of the holding is ploughed during July to August, and about the end of August to the middle of September seed is sown in nurseries. In four or five weeks the seedlings will be 3 or 4 inches above ground and are ready for transplantation in October to November or early in December. The ground is previously prepared by numerous ploughings, and the plants are placed in furrows 3 feet apart at a distance of 3 feet from each other. The ground must be kept free of weeds, and about a month after transplanting the small leaves are removed till only six to ten are left. About March to April plucking commences, and is continued till the rains break. On poor soil tobacco should be planted every three or four years only in the same place, but in good soil annual plantings may go on for twenty or twenty-five years. The expense of cultivation is calculated at an average of Rs. 40 per acre, and the total value of the outturn at Rs. 113.25 per acre.

Seasons.

DISEASES OF THE TOBACCO PLANT.—Howard (*U.S. Yearbook, Agri. Dept.*, 1898) gives useful particulars regarding the insect pests. So also various publications furnish details regarding Ceylon (*Trop. Agrist.*, xxv., 825; xxvi., 130). Delacroix (*Recherches sur Quelques Maladies du Tabac en France*, Paris, 1906) has published a full account of the most recent researches and has described the symptoms and methods of treatment of several diseases. He deals fully, for example, with the Canker, caused by a bacterium which he has named *Bacillus aeruginosus*; with Collar Rot (Pourriture du Collet) and Pith Rot (Pourriture de la Moelle), also due to bacterial organisms hitherto undescribed; with Foot Rot (Pourriture du Pied) due to *Fusarium tabacivorum*, Delacroix; with Mosaic Disease (La Nielle or Mosaïque); and with White Spot Disease (Maladie des Taches blanches), etc. So far as at present known, most of these blights do not seem to have appeared on the Indian tobacco plant.

Diseases.

Of the blights of tobacco, the best known are the broom rapes, *Orobancha indica* and *O. nicotianae*, common in most of the tobacco districts, especially in Bengal, Madras and Gujarat. Mollison states that in Gujarat a bad attack may sometimes destroy a quarter of the crop. The only practicable direct means of lessening its severity is the prevention of the parasite from forming seed. Another serious disease, in some districts, is the tobacco mildew, caused by the conoidal stage of

Broom Rape.

Mildew. *Erysiphe cichoracearum*, DC. Butler (*Proc. Board Agri., Pusa*, 1906, 82) remarks that it is probably the grey mildew which attacks the leaves in the Azamgarh district of the United Provinces, known as *kapti*. The same authority states that no remedy has been proved to be efficacious. "The application of sulphur either in form of 'flowers of sulphur' dusted on, or as potassium sulphide sprayed on, is efficacious in checking many mildews, but might interfere with the curing processes and be difficult to remove from the leaves." At Pusa a leaf-spot disease, due to *Cercospora Raciborskii*, Sacc. & Syd., is said to be common, but its effects are not very serious.

Pests. Maxwell-Lefroy enumerates the common insect pests of the tobacco plant in India under the following five heads:—

Grasshoppers. 1. Grasshoppers attacking newly transplanted seedlings. Clean culture and thorough tillage are the best preventatives. The only direct remedy is to dip the seedlings in standard lead arseniate mixture as they are planted.

Caterpillars. 2. Surface caterpillars, *i.e.* those living in the soil, hiding by day and emerging by night to feed on young plants. Search reveals their burrows, where they can be found and destroyed. The alternative methods are to poison the young plants or to put down baits of poisoned chaff.

Stem-borers. 3. The stem caterpillar, attacking young plants. These live in the stem and cause gall-like swellings. Plants up to a foot high are principally attacked. The cultivator's method of cutting open the gall by a longitudinal incision is probably the best.

Leaf-borers. 4. Leaf-eating caterpillars. When these appear on young plants, spraying the leaves with poison is a sound remedy. On old plants, the caterpillars must be picked off by the hand.

Cricket. 5. In Tirhut a cricket (probably the common burrowing *Brachytrypes achatinus*, Stoll.) is reported to injure the leaves by coming out at night and eating holes in them. Where they are not abundant they can be dug out, which is best done during August and September.

In seriously infested localities the most satisfactory treatment is to grow a crop such as lucerne and thoroughly poison it, thus poisoning off the crickets. In the United States of America flocks of turkeys are reared on the tobacco farms with a view to exterminating the caterpillars that do so much injury to the crop. [*Cf. Proc. Board Agri., Pusa*, 1906, 88, 94, 110-1, 113-4; Delacroix, *Sur une Maladie du Tabac*, le "Chancre" ou "Anthracnose," in *Comptes Rendus*, 1903, cxxxvii., 454; also *La Rouille blanche du Tabac*, etc., 1905, cxi., 678; Maxwell-Lefroy, *Mem. Dept. Agri. Ind.*, 1907, i., No. 2, 113-252.]

MANUFACTURE.

**Manufac-
ture.** **Withering.**—The leaves are considered mature when the texture becomes granulated and of a dark green colour with yellowish blotches. The lower leaves ripen first, the others in succession upwards. According to one system the leaves are cut off singly or in pairs (with a connecting portion of the stem), or the stem with its entire series of leaves is severed at once. The first stage in manufacturing is the withering of the leaf. This is usually accomplished by cutting down the plants or leaves and spreading these out on the ground, thus exposing them to the action of the sun for a few minutes or hours. They are then carried to the drying-house. But if rain falls during the withering, the plants or leaves must as rapidly as possible be carried to the drying-house and the reaping dis-

WITHERING, DRYING AND FERMENTING

continued. The withering-house may be constructed of any design or material providing free circulation of air. In the interior a framework of uprights and cross-rails has to be arranged, across which the sticks with withered leaf or withered plants suspended are placed and retained until the drying is complete. For the first two or three days the sticks with their suspended leaves are removed a foot apart and retained in that position until the mid-ribs are completely dried, which may take from fifteen to thirty days, according to the nature of the weather prevalent. In some parts of the country the first drying is accomplished by the leaves being spread on the floor over a layer of dry straw. Rapid drying produces yellow or almost green leaves, and slow drying darkens the colour.

Drying and Fer. enting.—When quite dry, the leaves (or stems with attached leaves) are taken down, usually assorted and, at the same time, separated from the stems and placed in heaps or stacks to ferment or sweat. For this purpose they are flattened out carefully, the stems or leaf-stalks being placed inwards and the tips of the leaves outwards. It is preferable to select a damp day to commence this operation. In the Rangpur houses, the floors being usually mud, the stacks of leaf are placed on boarding. Great care is taken that the leaves be spread out perfectly flat, and as a rule a selection is made of the finer leaf to be used for wrappers, from the coarser to be used as fillers. For this purpose it is accordingly customary to make two stacks, one of high-class, the other of low-class leaf. The stacks of leaf may be as much as 2 to 6 feet in height and the top is usually covered with a cloth or sheet of basket-work over which a weight is placed. It is customary on the second or third day to pull down two stacks of the same quality simultaneously, and to construct new stacks, taking leaf alternately from the one and the other, observing the while that the leaf in the centre of the first stacks may be in the exterior of the new ones. A week later the stacks are similarly pulled down and remade, and this may be continued time after time for a month or six weeks—in other words, until all the heat of fermentation has disappeared. In this way uniform and continuous fermentation is ensured.

Bundling and Baling.—The leaves are then tied into bundles of 25 or 30, a useless leaf being employed in tying each such bundle. Great skill is required in this operation, since the leaves must be left perfectly flat, the bundles being almost fan-shaped. In this condition they are baled, the broom-like ends projecting outwards.

It may be as well to contrast this (which may be taken as the system pursued in 1902 when personally inspected by me in Rangpur) with that given by Buchanan-Hamilton as observed in Dinajpur (the adjoining district) during 1809–11. The tobacco, he says, is “fit for cutting in March and April. Each stem contains from 5 to 8 leaves, which in a good soil are 18 inches long, and in a poor are only half the length. The stem is cut, and the plants are allowed to lie three days on the ground. The leaves are then separated, and are tied in handfuls, which are hung in the open air until dry. The handfuls are made into balls, by laying them together in two rows, with their roots outward. The parcels are surrounded with straw, are tied very tightly, and the bale is then complete.”

Whitney and Floyd (*Growth of Tobacco Industry, U.S. Yearbook, Agri. Dept., 1899, 429–40*) show the bundles or “hands” as produced in Maryland and Virginia, also the forms adopted with the “Cigarette and Manufacturing Tobaccos,” “Connecticut Cigar-wrapper Leaf,” the “Ohio Limmer

Spanish Cigar-filler Leaf," the "Florida Cigar-filler Cuban Seed." [Cf. Floyd, *World's Exhib. Leaf Tobacco at Paris Expos.* 1900, in *U.S. Yearbook, Agri. Dept.*, 1900, 157-66; McNess and Mathewson, *Dark Fire-cured Tobacco of Virginia, etc.*, *U.S. Yearbook, Agri. Dept.*, 1905, 219-30.] Much depends, apparently, on the care in handling and the skill in making up the bundles. There would accordingly seem every prospect of limitless expansions of the Indian tobacco trade, through the simple bestowal of greater care in the manufacture and in the methods of bundling and handling the leaf. Although the past century has witnessed a great advance there is still much room for improvement. Any one who will take the trouble to inspect the chief tobacco area of India will readily discover that the fault is not so much the climate, soil and plant, as the defective methods of curing that consign the Bengal tobacco to the humble position it usually occupies in the markets of the world.

Changes
during
Manufacture.

Changes occurring during Manufacture.—Dr. Harold H. Mann, in a communication with which I have been favoured, discusses the modern opinions on this subject:—"It has been repeatedly pointed out by writers on this subject that dry *Nicotiana Tabacum* leaf is not tobacco. Delacroix (*Bull. Scient. Pharm.*, Feb. 1905, No. 2) remarks, for example, that the quantity of albuminoids present in the normal leaf gives a disagreeable odour to the smoke that recalls that of burning wool or horn. The fermentation which the leaf undergoes during manufacture is, in fact, essential to the preparation of tobacco, and if not carried out properly, the finest leaf may be rendered entirely worthless. Many theories have been held at various times as to the nature and cause of the great changes which take place, and it has been successively believed that they were due simply to the oxidising action of the atmosphere at the high temperature which was produced (100° to 120° F.), (Schloesing, Nessler); that definite microbes or bacteria were the necessary agents in producing the flavour of tobacco (Suchsland, Koning, Vernhout), and even that each class of tobacco had its own special bacterium; and that such changes as occur are principally, if not entirely, due to the presence and action of oxidising enzymes or unorganised ferments (Loew). It is now almost universally recognised that oxidising enzymes are the principal agents in producing the development of the colour and aroma characteristic of prepared tobacco leaf.

Enzymic
Action.

"These enzymes, which were first isolated and examined by Oscar Loew in America, appear to be at least three in number. The first of these (*oxidase*) is an exceedingly active ferment, but very susceptible to noxious influences, being destroyed by heating to the very moderate temperature of 150° F.; the second (*peroxidase*) is not nearly so active, but is more resistant, and is only destroyed at 190° F.; the third (*catalase*) is of a different character, more resistant than either, but the part it takes in the processes of manufacture is not yet understood. The processes of curing (drying) and sweating (fermentation) of the tobacco leaf are accompanied by a destruction of these enzymes present in the leaves; the *oxidase* and *peroxidase* generally survive the curing process but the former of these finally disappears in the sweating (fermentation), leaving the more resistant *peroxidase*.

Oxidase.

Peroxidase.
Catalase.

Sugar.

"The changes induced by these ferments are very considerable. During the drying (curing) of the leaves, the starch is transformed, and the greater part of the sugar which results disappears. The albuminoids decrease

in amount: the tannin also decreases, and it seems probable that this decrease may be the principal cause in the change of the colour of the leaf. In the sweating or fermentation which follows, the last traces of sugar disappear; nicotine decreases in quantity and there is a corresponding increase in the amides resulting from its decomposition. The leaf becomes more alkaline, and further progressive changes take place in the colour and aroma. A slow after fermentation then takes place, during which the colour and aroma gradually become ripened. During or after sweating the tobacco is often sprinkled in America with a so-called 'petuning' liquid, the composition of which is kept secret, but whose principal function seems to be to increase the alkalinity of the leaf and so hasten the changes already described."

Petu g.

I proved Methods of Manufacture.—In some of the experiments conducted by the Agricultural Department of the United States, it has been shown that during fermentation certain undesirable changes take place together with the disappearance of a large amount of nicotine. Accordingly the system of fermenting in stacks has been condemned and the substitution of closed fermentation tanks recommended. This American system, however, is not sufficiently used as yet to justify its being recommended for India. A small quantity of already fermented tobacco is placed along with the new leaf in order to start the fermentation.

Improv ents.

Enough has been said to indicate the transitional stage of modern research into tobacco manufacture and the complete lack of knowledge that prevails in India. It is no matter for surprise, therefore, that the Government of India should have deemed a tobacco expert imperatively necessary. Rapid and satisfactory though the progress has been in certain directions of the Indian trade, skilled supervision and definite research locally conducted seems almost certain to effect improvements calculated to place India in the foremost ranks of the tobacco-producing countries of the world.

India's Future
Position.

NATIVE AND EUROPEAN MANUFACTURED TOBACCOES.—With the Natives of India crudely cured tobacco-leaf is usually reduced to a powder, damped, mixed with *gúr* (pp. 952, 1109), also various flavouring ingredients, and thus made into large cakes. In this form it is sold to the consumer. The pipe ordinarily used is a hollow vessel or cocoanut shell partially filled with water. From this vessel arise two tubes—one the mouthpiece, the other the attachment for the actual pipe, the *chilam*, or vessel containing the tobacco. The smoke is thus drawn through water before reaching the mouth. The tobacco is ignited with a live coal or burning cake of specially prepared charcoal.

anufac-
tures.Mixed with
Sugar.

Water Pipe.

The crudely prepared leaf is simply rolled between the hands, compressed into a conveniently sized ball, and placed within the *chilam*. But with many of the hill tribes a crude pipe is used that hardly differs from that employed in Europe—the boll being made from a short joint of a bamboo and the stem a common reed. Indeed in many cases the pipe may be constructed, for each smoke, of soft mud placed on a stone, the boll having a small opening at the bottom against which the lips are pressed in smoking. It is only of South India and Burma that it can be said that smoking cigars has become so general that it can be described as a widespread habit. But within recent years great progress has been made in local cigar manufacture, and steadily the practice of cigar-smoking seems to be gaining ground with the better classes of Natives all over the country.

Crude Pipes.

Cigara.

Cigarettes.	And it is customary to read in the public press of the rapidity with which the habit of cigarette-smoking has invaded the social life of the various races and peoples of India.
"Trichy."	Indian Cigars. —One of the first persons who realised the possibilities of an Indian cigar trade was Capt. E. A. Campbell, who, in 1876, started a company at Dindigal to improve the well-known "Trichy" of former times. Two years later, however, the company was wound up and little progress made till about 1881, when it was discovered that by importing wrappers from Java and Sumatra a cigar could be turned out that would please the eye of the consumer better than that constructed throughout of Indian leaf. This discovery gave at once the impetus that was needed to bring the excellent cigars of South India to the favourable notice of the world at large. A factory inspected by me in 1903 was found to give employment in all its departments to fully a thousand persons—men, women and children. It was ascertained that the usual rate for an expert worker was to produce 400 to 800 cigars a day, according to skill, thus earning from Rs. 20 to Rs. 30 a month in wages.
History of Indian Manufacture.	But it is perhaps one of the most remarkable features of the tobacco traffic that no attempt has been made by Europeans to organise a tobacco-manufacturing establishment either within the great producing area of Bengal itself or in Burma, where the Bengal leaf is worked up and again returned in the form of the cigars for which Burma has been so long famous.
Wages.	
Bur Cigars.	
Chemistry.	Industrial, Chemical, etc. —It would be beyond the scope of this work to discuss all the side issues and technical investigations. The <i>Pharmacographia Indica</i> (ii., 632–43) will be found to set forth the salient features of most of these side issues. The <i>Kew Bulletin</i> (Feb. 1896, 49–55) furnishes details regarding the natural sugar present in tobacco. Many publications have dealt with <i>tobacco juice</i> —a substance prepared in France and sold by all the licensed vendors. It is claimed to be free from all matter susceptible of fermentation and to contain no resinous substance, but a higher percentage of nicotine than would be the case with an infusion of the leaf. Tobacco juice is largely used as an insecticide. Espin published in the <i>Bulletin of the Botanical Department of Trinidad</i> for 1900 a highly instructive account of tobacco cultivation, manufacture and trade. This was followed up by a most instructive little book issued by Sir D. Morris, Imperial Commissioner of Agriculture for the West Indies, entitled <i>The Cultivation and Curing of Tobacco</i> (1905). The <i>Tropical Agriculturist</i> (Oct. 1905, 595; Jan. 1906, 819–26, etc.) contains papers of great interest on the cultivation and manufacture of tobacco in Ceylon.
Sugar.	[Cf. Heuzé, <i>Les Pl. Indust.</i> , 1895, iv., 43–90; Arthur Wigham, <i>English-grown Tobacco</i> ; Kissling, <i>Chem. Anal. of Tobacco</i> ; Jenkins, <i>Effects of Fert.</i> ; Whitney and Means, <i>Changes in Fern. Cigar Leaf</i> , U.S. Dept. Agri., 1899, No. 60; Haase, <i>Tobacco Free or Partly Free from Nicotine</i> ; Pietet and Rotschy, <i>New Alkaloids of Tobacco</i> ; Julius Mohr and others, <i>Delic Tobacco of Batavia, Tobacco under Shade</i> , etc., etc. (numerous papers); Koning, <i>Der Tabak, Kultur und Biologie</i> , 1900; Loew, <i>The New Enzyme in Cured Tobacco—Catalase</i> ; Schweiz, <i>The Chem. of Tobacco Smoke</i> ; Thorpe and Holmes, <i>The Paraffins of Tobacco Leaf</i> ; G. Juice.	
Trade.	TRADE IN INDIAN TOBACCO. —During the opening decade of the 19th century India was not known to the commerce of the world as a tobacco-producing country. By 1825, however, we read of Masulipatam in South India producing very superior tobacco, and that snuff was
Masulipatam.	
Indian Snuff.	

CIGAR TRADE

about that time also sent from India to England. In 1833 was published Buchanan-Hamilton's account of Dinajpur (which was possibly written about 1809 to 1811). He speaks of tobacco cultivation much as if it had been even then a well-known crop (see p. 805). It was apparently not fermented at all—simply dried leaf.

Exports.—By 1866-7 the Exports of tobacco from India were valued at Rs. 5,61,836, of which only Rs. 7,088 worth were consigned to the United Kingdom. But there is no mention of cigars in these early trade returns; and what is more curious still, Bombay was by far the most important source of the Indian supply. Ten years later (1876-7) the exports were rendered under three headings:—Unmanufactured Tobacco, 10,508,720 lb., valued at Rs. 7,51,375; Cigars, 190,136 lb., valued at Rs. 1,17,445; and Other Manufactured Tobaccos, 205,033 lb., valued at Rs. 22,578. Ten years still later (1886-7) the exports were:—Unmanufactured, 9,868,834 lb., valued at Rs. 9,57,156; Cigars, 273,209 lb., valued at Rs. 2,11,391; and Other Sorts, 193,996 lb., valued at Rs. 27,036. Again, ten years still later (1896-7), the exports were:—Unmanufactured 11,257,582 lb., valued at Rs. 11,38,204; Cigars, 557,816 lb., valued at Rs. 6,37,812; and Other Sorts, 273,872 lb., valued at Rs. 37,318. For the most recent years (taking values only) the following were the exports:—

Exports.

Early Transactions.

Classification.

—	1900-1.	1901-2.	1903-4.	1905-6.	1906-7.
Unmanufactured	Rs. 6,48,102	17,86,132	12,86,241	14,07,241	20,49,623
Cigars	Rs. 8,64,254	16,40,427	7,72,799	8,80,903	9,97,489
Other Sorts ..	Rs. 36,745	42,440	37,639	52,293	48,866
TOTAL ..	Rs. 15,49,101	34,68,999	20,96,679	23,40,437	30,95,978

The cheap tobaccos returned under "Other Sorts" are Native preparations consigned to the Maldives, the Straits, Ceylon and Arabia. Perhaps the most remarkable feature of the foreign traffic is the growth of the supply of cigars. The exports of this class expanded from a valuation of Rs. 1,17,445 in 1876-7 (when first separately returned) to Rs. 16,40,427 in 1901-2, and Rs. 9,97,489 in 1906-7. And it is significant that, in what might be called normal years, these exports go mainly to the United Kingdom and the Straits Settlements. The years 1901-2 and 1902-3 were abnormal, since in these years very large consignments were made to Cape Colony and Natal—doubtless to meet the demands of the British soldiers. Further, it may be added that the bulk of the cigars exported from India go from Madras and Burma.

Growth of Cigar Traffic.

Consigned to the United Kingdom.

Of the unmanufactured tobacco, Bombay exports by far the largest quantity (on an average about one-half the total). And what is remarkable, the receiving countries are Aden, the Straits Settlements, China (Hongkong) and Holland, the last-mentioned having for some time steadily increased its demands for the very cheapest of the Indian unmanufactured tobaccos. No Indian unmanufactured tobacco would appear to go to the United Kingdom. Bengal, the chief producing province, exports to foreign countries, as a rule, only about half the quantity supplied by Bombay. But the explanation of this circumstance is perhaps to be had in the fact that by the coastwise traffic Bengal is shown to export to Burma unmanufactured tobacco (in 1905-6) to the value of Rs. 27,68,296. The importance of Burma to the Indian grower is made

Unmanufactured Tobacco.

Bengal Exports.

still more evident when it is added that at the same time Madras contributed to Burma unmanufactured tobacco to the value of Rs. 14,72,433. Thus Burma is to the Indian grower of unmanufactured tobacco a very much more important market than the rest of the world collectively.

Imports.

I ports.—Turning now to the IMPORT Traffic, a similar expansion may be said to be observable. In 1876-7 the traffic under all classes was valued at Rs. 9,56,880. Ten years later (1886-7) at Rs. 49,53,486; the following decade (1896-7) at Rs. 26,30,258; in 1904-5 at Rs. 55,62,850; in 1905-6 at Rs. 66,08,807; and in 1906-7 at Rs. 69,33,377. The most noteworthy feature of this trade is the growth of the demand for foreign cigarettes. The year 1900-1 was that in which the returns of cigarettes were made apart from cigars. They were then returned as 1,165,399 lb., valued at Rs. 17,03,968; while in 1904-5 they were 2,518,659 lb., valued at Rs. 35,08,187; in 1905-6, 3,119,071 lb., valued at Rs. 44,97,699; and in 1906-7, 2,912,841 lb., valued at Rs. 45,97,364. On the other hand, if an opinion can be formed of a traffic for so limited a period as six years, the imports of cigars would seem to have manifested nothing like the interest taken in the cigarettes. In 1900-1 the imports of cigars were 60,157 lb., valued at Rs. 2,34,209; in 1904-5 they were 118,020 lb., valued at Rs. 3,75,958; in 1905-6, 101,293 lb., valued at Rs. 3,49,136; and in 1906-7, 111,586 lb., valued at Rs. 4,03,330. This state of affairs may be a direct consequence of the continuous improvement that for some years past has been maintained in the Indian-made cigar.

Foreign
Cigarettes.

Influence
of Indian
Production.

Supply from
United
Kingdom.

Of the imports of cigarettes in 1900-1 (1,165,399 lb.), 610,980 lb. came from the United Kingdom and 362,760 lb. from the United States, while 887,882 lb. of these imports were taken by Bengal. Of the supply for 1906-7 (2,912,841 lb.), 1,818,057 lb. came from the United Kingdom and 782,596 lb. from the United States. The supply from the Straits Settlements seems to fluctuate very greatly, but for the past two years has declined seriously. In 1903-4 the imports came to 177,294 lb., but in 1905-6 were 19,228 lb., and in 1906-7, 15,053 lb. China (Treaty) Ports have similarly given indications of a contraction: in 1903-4, 203,134 lb.; in 1905-6, 163,661 lb.; and in 1906-7, 112,528 lb. Bengal continued to hold the supremacy as the receiving province, since out of the total it took in 1906-7, 1,755,852 lb.; Burma and Bombay following with respectively 438,723 and 309,385 lb. Robertson (*Rev. Trade Ind.*, 1904-5, 11) remarks: The cigarette imports have thus in five years increased 106 per cent., and the quantity imported last year represents 840 million cigarettes. The average value per pound was Rs. 1-4-5 British, Rs. 1-1-2 American, Rs. 6-9-1 Egyptian, and those from the East, 15 annas 9 pies, the value per 1,000 being roughly three times the value per pound. Noël-Paton (*Rev. Trade Ind.*, 1905-6, 15) shows the quantity to have further increased by 23·8 per cent. on that for 1904-5: "The average value per lb. from each of the sources was:—British, Rs. 1-8-10; American, Rs. 1-1-6; Egyptian, Rs. 6-4-3; and Eastern 13 annas."

Percentage
Increase.

Cigar Trade.

Speaking of the modern cigarette trade, J. E. O'Connor (*Anglo-Ind. Rev.*, April 1903) observed: "Within the last three or four years, however, a singular modification of popular taste has been witnessed, one which would hardly have been believed possible in such a country and amongst such a people. Some enterprising firms in Europe thought they saw an opening in India for the Native consumption of American tobacco in

cigarettes in supersession of the *hookah* (or water-pipe) still commonly used by the people. Acting on this idea they imported cigarettes in increasing quantity at rates bringing them within the reach of the masses, and in a very short time the arrangements made for bringing the cigarettes within easy reach of the consumer had a very manifest effect. At the present moment the value of the cigarettes imported is about £150,000 a year, and allowing for the proportion of better class cigarettes imported for Europeans it is clear that the trade is already extensive. As yet, moreover, it is practically confined to a few large towns, and is only beginning. To say that it may increase tenfold is to use most moderate language. Why should the supply of these things be allowed to come from abroad?"

Of the cigar trade in 1900-1 (60,157 lb.), 18,295 lb. came from Belgium; 11,654 lb. from the Philippines; 7,605 lb. from the Straits Settlements; 5,307 lb. from the United Kingdom; and 4,777 lb. from China—Hongkong. In 1906-7 (111,586 lb.), 38,420 lb. came from Belgium; 28,448 lb. from China—Hongkong; 21,759 lb. from Holland; 5,650 lb. from the United Kingdom; 2,992 lb. from the Straits Settlements; and 450 lb. from Natal, the supply having greatly decreased.

NIG LLA ATIVA, Linn. ; Prain, *Beng. Plants*, 1903, i., 194. **RANUNCULACEÆ**. The Small Fennel or Black Cumin, *kālājīra*, *kalónjī*, *mugrela*, *karun-shiragam*, *nalla-jīlakra*, *karijirigi*, *samon-né*, etc. A native of Southern Europe, but extensively cultivated in India for its seeds.

These contain two kinds of OIL, one dark-coloured, fragrant and volatile, the other clear, nearly colourless, and of about the consistency of castor oil. **MEDICINALLY** they are regarded as aromatic, carminative, stomachic and digestive. By the Natives they are much used in curries, in vinegar (p. 1110), and other dishes, and are frequently sprinkled over the surface of bread along with sesamum seed. [Cf. *Pharmacog. Ind.*, i., 28-9; *Agri. Ledg.*, 1895, No. 10, 168, 171; 1896, No. 28, 271; 1899, No. 12, 150; Thorpe, *Dict. Appl. Chem.*, 1899, ii., 397; Gildemeister and Hoffmann, *Volatile Oils*, 1900, 352; Dutt, *Mat. Med. Hind.*, 1900, 102-3. (For the true Cumin, see pp. 442-3; black C away, p. 283.)]

Oils.

Medicine.
Vinegar.

IL , IL- , FAT , TC., AN P FU Y.—

The Oils and Fats may be classified by many systems depending upon their chemical, physical and industrial properties and uses. Or they may be grouped according as they are derived from the animal, vegetable or mineral kingdoms. Some are spoken of as fixed, others as essential, edible, medicinal, drying, non-drying, etc., or again as illuminants, lubricants or as suitable for candle-making, soap-making or perfumery. Blount and Bloxam (*Chem. for Engin. and Manuf.*, etc., 1900, ii., 223) observe that fats, tallows, waxes, etc., are chemically of the same nature as the substances popularly designated oils. They are characterised by their unctuousness, by their insolubility in water, and by their solubility in ether, benzene, carbon bisulphide, and by their leaving a greasy stain on paper, which does not disappear by evaporation. Chemically they are ethereal salts of fatty acids, the alcohol radicle of the salt being glycerine (glyceryl), except in certain waxes where radicles of higher alcohols occur. Popularly, however, fats are viewed as distinct from oils, but it serves no good purpose to separate them.

D. P.,
v., 446-79.
Oils and
Oil-seeds.

Paint.

To the Natives of India OILS might be described as chiefly of interest as articles of diet or as illuminants. They are but rarely employed as lubricants. The painting of woodwork is a luxury of the wealthy. With the peasant, the ornamentation of the implements of his trade or the materials of his pastime are coloured, when coloured at all, on the turning-lathe and by means of lac. The dyers and leather-workers, however, all

Uses of Oil.

use oil, and have done so from the remotest antiquity. One of the most important Indian uses of oil, and one comparatively unknown in Europe, is the anointment of the person with mustard or rape and a few other sweet oils. The use of soap as a personal detergent cannot be said to be more than a luxury, and indeed, to the mass of the people, an unknown luxury. Crude soap is, however, largely manufactured and sold in every village to be employed by the washermen and dyers.

Candles.

Candles were never very extensively used by the Natives of India, but the modern demand for kerosene oil and the cheap German lamps, specially designed for service with mineral oils, has largely supplanted the candles of former times. In fact the great popularity of kerosene and other mineral oils, within recent years, has doubtless curtailed the cultivation and manufacture of most of the minor oils, more especially those intended as illuminants and lubricants. It is a matter of twenty-five to thirty years ago, at most, since every European resident in India, and all the wealthier Natives, employed either castor or cocoanut oil exclusively for house illumination. The subsequent introduction of refined kerosene from America drove these completely out of use, and that too within a remarkably short time, just as electricity seems destined to displace kerosene and gas. The introduction of less pure though cheaper Russian oil and the invention of cheap lamps (already mentioned) may be said to have marked the still greater displacement of vegetable illuminating oils. Kerosene has, in fact, effected a revolution in the domestic economy of the people of India that is marked by an increasing demand for luxury and convenience, one of the many expressions of prosperity that come direct from the peasantry. The present article will be made, as far as possible, to exclude Petroleum (p. 875), though in some instances this may be impossible (*e.g.* candles) when the returns do not separate the mineral oils and their manufactures from the corresponding vegetable and animal products.

Cheap Lamps.

Chief Oils
and Fats.

The following are the chief sources of the vegetable and animal OILS and FATS of INDIA, in the sequence of their scientific or trade names :—

Arachis—the Earth-nut (see pp. 76, 80-3); **assia**—the *Mahua* (p. 120); **rassica**—Mustard and Rape (pp. 183-6); **utter** (pp. 475-8); **Ca ellia**—Tea-seed; **Ca phor** (p. 247); **Ca abis**—Hemp (pp. 256-7); **Cartha us**—Safflower (pp. 281-3); **Cocos**—Cocoanut (*Kopra*) (pp. 357-60); **Dipterocarpus** (*Eng*) (pp. 501-2); **Fish-oil** (pp. 544-5); **Garcinia**—Kokum Butter (p. 553); **Ghi**—Clarified Butter (pp. 478-82); **Gossypiu**—Cotton-seed (pp. 612-3); **Guizotia**—Niger-seed (p. 625); **Juglans**—Walnut (p. 700); **Lard** and **Tallo** (pp. 701-3); **Linu**—Linseed (pp. 725-31); **oringa**—Ben Oil, (p. 784); **Papaver**—Poppy-seed (p. 860); **Ricinus**—Castor (p. 922); **esa u**—*Til* or Gingelly (pp. 986-7); and **Wax** (*ees'*) (pp. 125-7).

There are many others that of course might be mentioned, but the above are representative of the Fats and Oils of commercial importance. In passing, reference may be given to *Bombax* (see p. 168); *Cochlospermum Gossypium*, DC., the White Silk-cotton Tree

IMPORTS AND EXPORTS

(Hooper, *Rept. Labor. Ind. Mus.* (Indust. Sec.), 1906-7, 9); *Helianthus annuus*, Linn., Sunflower (Hooper, *Agri. Ledg.*, 1907, No. 1); and to *Olea cuspidata*, Wall., the Indian Olive, which in Kohat fruits abundantly (Hooper, *l.c.* 1904-5, 25). In the present article it is proposed to give in one place a brief sketch of the oil interests of India collectively (exclusive of petroleum and its derivatives). Collective treatment is necessary, not only to link together kindred information but to exhibit the returns of oils and fats (given in trade statistics as "Others"), which by any other treatment would be omitted from this work.

FOREIGN TRADE IN OIL-SEEDS, OILS, FATS, ETC.

The official returns here discussed may be viewed as separated into two Trade. great groups—IMPORTS and EXPORTS. Under each of these sections may be formed, such as Fixed and Essential, with sub-sections, Vegetable and Animal, and under these again still further groupings, according as the substances are raw or manufactured. Taking the first year for which fairly complete returns exist (1876-7), then twenty years later (1896-7) and the most recent years (1905-7), the following statement may be accepted as exhibiting the values of the more interesting transactions in the combined traffic:—

I ports fro Foreign Countries.

I ports.

(A) Fixed.	1876-7.	1896-7.	1905-6.	1906-7.
(a) VEGETABLE.	Rs.	Rs.	Rs.	Rs.
1. Oil-seeds	1,37,191	7,06,575	2,95,548	3,76,009
2. Oils	2,41,930	31,73,292	14,40,805	26,33,724
(b) ANIMAL.				
3. Oils	10,664	2,19,761	4,62,361	5,70,655
4. Butter	85,383	2,01,443	3,12,510	2,66,636
5. Ghi	2,76,395	4,28,432	1,79,483	2,13,861
6. Tallow	62,671	1,99,157	8,16,705	9,14,834
7. Lard	—	—	59,536	92,370
8. Wax (excl. Candles) ..	1,48,416	7,093	13,634	24,875
(c) MANUFACTURES.				
9. Candles (incl. Paraffin) ..	8,92,918	10,99,751	8,67,983	7,32,438
10. Soap	3,32,791	11,70,670	31,90,890	32,28,156
11. Oil and Wax Cloth, etc.	17,620	2,99,150	5,96,666	6,20,305
(B) Essential.				
12. Oil-seeds	58,986	1,44,407	1,22,978	1,69,306
13. Oils	40,363	1,15,661	1,82,501	2,03,506
14. Perfumery	4,18,851	2,14,570	2,88,954	2,61,299
GRAND TOTALS	27,24,179 £181,612	79,79,962 £531,998	88,30,554 £588,703	1,03,07,974 £687,198

It will thus be seen that while for approximately the past thirty years the imports have increased threefold, during the past eight or nine years they have manifested a tendency to decrease. Prior to 1906-7 the highest year on record was 1901-2, when the total of the above articles came

Soap. to Rs. 94,66,769 (or £631,118). The most significant feature of the returns is the expansion of the demand for soap, namely from a valuation of Rs. 3,32,791 in 1876-7 to Rs. 31,90,890 in 1905-6 and Rs. 32,28,156 in 1906-7. The growth of this traffic has been continuous, notwithstanding the fact that within the period dealt with India has made rapid progress as a soap-manufacturing country. So also the expansion of the demand for the goods treated under Oil and Wax Cloth is certainly remarkable, seeing that the textile used for linoleum is jute, which is specially manufactured in Calcutta and sent to Europe and America to be subjected to its final transformation into the goods which reappear under the imports indicated. The decline of the imports of *ghi* and the enhancement of those of butter and tallow are also worthy of note, the more so since the consumption of foreign candles has practically remained stationary for the past thirty years.

Linoleum.

Exports.

Exports to Foreign Countries.

It may now be useful to set forth in a parallel series of quotations the exports from India of the Oil-seeds, Oils, and Manufactures therefrom :—

	1876-7.	1896-7.	1905-6.	1906-7.
(A) Fixed.				
(a) VEGETABLE.	Rs.	Rs.	Rs.	Rs.
1. Oil-seeds	5,28,96 873	7,95,41,000	10,40,17,449	12,82,97,037
2. Oils	28,54,997	47,96,437	53,99,475	46,77,307
3. Oil-cake	—	19,17,673	{ 51,99,194 { 16,99,186 (for manure)	{ 35,89,740 { 40,09,381
4. Dregs of Oil ..	6,70,935	1,79,515	—	—
(b) ANIMAL.				
5. Oils	63,088	1,691	6,543	23,171
6. Ghi	3,57,250	15,00,990	29,38,771	22,65,443
7. Lard	3,22,825	67,900	18,750	15,747
8. Tallow	31,234	95,574	1,11,255	80,404
9. Wax (other than Candles) ..	—	2,76,190	7,31,320	5,96,009
(c) MANUFACTURES.				
10. Soap	3,72,059	64,260	10,867	6,688
(B) Essential.				
11. Oil-seeds	2,94,367	5,75,801	20,74,818	19,20,257
12. Oils	1,80,130	2,32,601	7,11,318	8,12,746
13. Perfumery (Musk)	1,17,256	19,255	11,180	14,500
„ Others	1,64,371	82,795	1,49,639	1,51,441
GRAND TOTALS ..	5,83,25,385 £3,22 1,692	8,93,51,682 £5,956,778	12,30,79,765 £8,205,317	14,64,59,871 £9,763,991

Thus in approximately thirty years the exports under the above-mentioned articles have increased from a valuation of $3\frac{1}{2}$ to $9\frac{3}{4}$ million pounds sterling. But to obtain a full conception of the importance of Indian foreign transactions in oils and oil manufactures, it is necessary to add the imports to the exports, when it is seen that the total traffic has expanded from a valuation in 1876-7 of $3\frac{1}{2}$ million to over $10\frac{1}{2}$ million pounds in 1906-7.

Total Interests.

Oil-seed Traffic.

Cotton-seed.

Perhaps the most important feature in these returns is the steady progression of the oil-seed traffic, which in 1876-7 stood at a valuation of £3,526,458 and in 1904-5 had expanded to £9,499,961, but contracted to £6,934,496 in 1905-6, and became £8,553,135 in 1906-7. And when the details of these exports are looked into it is found that the traffic in cotton-

seed has expanded during the past five years from a valuation of £36,999 in 1900-1 to £410,840 in 1904-5, £681,173 in 1905-6, and £866,043 in 1906-7. That is to say it has expanded from being utterly insignificant until now it holds the second place in quantity and the fourth in value of all the oil-seeds. The bulk of cotton-seed exports go from Bombay to the United Kingdom. Although less in value, relatively, the expansion of the traffic in oils, in *ghi* and essential-oil seeds is no less interesting and valuable.

INTERNAL TRADE.

But splendid though these results are, they show very possibly little more than two-thirds of the actual value to the country, the remaining third representing the consumption of raw material or of the local manufactures therefrom. But while it is easy enough, from personal acquaintance with the country, to hazard opinions that may be found fairly accurate, it is often by no means possible to substantiate such by actual statistical returns. It has been found the only satisfactory course in dealing with the above (foreign transactions) to take the declared values at the ports, since in some cases the quantities may be in gallons, in others in cwt. or in yards. On referring to the official returns of internal trade, as manifested by the rail-borne traffic, the quantities only are given, and these are expressed in cwt. No relation can, therefore, be worked out between the railway goods traffic and the valuations of the exports and imports recorded at the customs houses. Still, as they stand, the railway returns are instructive. Some of the more important materials and movements, as learned from a study of these returns, may be here briefly reviewed. So also, in the same way, a study of the transactions by sea coastwise gives additional particulars of the inter-provincial exchanges and of local consumption. These transactions are given in cwt., so that a comparison with the railway returns is possible, but not with the foreign transactions nor for years later than 1905-6.

Internal
Trade.

Rail and River.

Coastwise.

OIL-SEEDS.—In the *Agricultural Statistics* the following are the headings usually accepted, and under which alone areas of production are recorded—Linseed, Til, Rape and Mustard, and Others. In the returns of Foreign Trade a more comprehensive series is given, namely Cotton, Castor, Earth-nut, Linseed, Mahua (“Mowa” or “Mowra”), Mustard, Poppy, Rape, Til, and Others. Lastly, in the published returns of rail-borne traffic we find a third grouping, namely Linseed, Rape and Mustard, Til, and All Kinds collectively, the last heading including the three separate kinds as well as the Others of *Agricultural and Trade Statistics*. With the exception of linseed and *til*, no analysis of the returns of oil-seeds is possible that would approximately exhibit the relations of production to consumption.

Oil-seeds.
Production and
Consumption.

Area.—The majority of the oil-seeds and oil-yielding materials enumerated in the opening paragraphs above are, however, regular agricultural crops, and accordingly appear in official statistics in some position or other. A few, such as the cocoanut, the *mahua*, the walnut, etc., are, however, trees, and can hardly be classed as regular agricultural crops. Another series afford oil-yielding seeds as a supplementary crop, such, for example, as cotton, hemp, safflower, poppy, tea, etc. The others in *Agricultural Statistics* would, therefore, not include these by-product oils, but would consist of the minor oil-seeds proper, such as earth-nut, niger and castor. To the areas returned as oil-seeds would, therefore, have to be

Rail-borne
Oil-seeds.

added some portions of the acreages returned under cotton, hemp, poppy, etc., and an estimate made for the areas of the oil-yielding trees, before a full conception could be obtained of the total area of India normally concerned in its oil traffic. But taking the statistics of the oil-seeds as published, the area devoted to these crops would seem to have expanded considerably within the past few years. In 1899-1900 the total came to 10,327,641 acres in the British Provinces alone, in 1903-4 it had expanded to 14,545,966 acres, in 1904-5 stood at 13,518,768 acres, and in 1905-6 was 12,501,253, with, say, another million acres in the Native States. But to that vast area would, as just explained, have to be added some portion of the land devoted to cotton (which for the years 1904-7 has averaged 21 million acres), as also the area under all the other plants enumerated above that, like cotton, afford oil-seeds as by-products.

Of the more important oil-seeds it may be said that *til* or *jinjili* (*Sesamum indicum*) is the most abundant and most widely cultivated of all. It occupied, according to the *Agricultural Statistics*, over 4 million acres in 1904-5, distributed chiefly in Burma, the Central Provinces, Madras and Bombay (including Kathiawar and Baroda). Then come rape and mustard with almost $3\frac{1}{2}$ million acres, mostly in Bengal and the Panjáb. Lastly, linseed, a good third, with some 3 million acres, very largely in Bengal, the United Provinces and the Central Provinces. The final reports issued by the Commercial Intelligence Department estimate the areas for 1906-7 under these crops as follows:—rape and mustard, 4,196,500 acres (pure) and 2,210,000 acres (mixed); sesamum, 3,863,100 (pure) and 775,000 (mixed); linseed, 3,028,200 acres (pure) and 663,000 acres (mixed); but in the case of sesamum the area for Burma is not included. Linseed is the rent-paying oil-seed crop, only about 6 per cent. of the annual average outturn being retained in the country. The other two crops, *til* and mustard and rape, are very much more largely consumed locally, and are accordingly not so immediately influenced by the fluctuations of the foreign markets. But a disturbing element in estimates of area and production occurs, as already partially indicated, in the very large export trade in cocoanut oil, and in the material (*kopra*) from which that oil is expressed, through the fact that no area of production can be given for these products. Moreover, *kopra* (or dried cocoanut kernel) is exported, to some extent at least, as an article of food. It is at all events not treated as an oil-seed in any of the official returns, though it affords an important oil.

Traffic.—Turning now to the official publications that furnish information regarding the internal trade, we learn from the returns of rail-borne goods that the most important receiving province is ordinarily Bengal (an average of over 1,100,000 cwt. for the years 1902-7, drawn chiefly from the United Provinces and Calcutta). Next the Panjáb, with an average of about 1,000,000 cwt. for the same period), depends upon the United Provinces almost exclusively for its external supplies, which, moreover, are chiefly classed as Other Oil-seeds. Then comes Madras with an average of about 400,000 cwt. Lastly, Bombay imported during the same period an average of about 400,000 cwt. of oil-seeds of all kinds, chiefly from the Nizam's Territory and Mysore. But the internal transactions of the provinces (the strictly local trade) is normally only $3\frac{1}{2}$ million cwt. (for example, 3,478,180 cwt. in 1904-5 and 3,307,669 cwt. in 1905-6), while the receipts of the port towns came in 1904-5 to 30,890,818 cwt., in 1905-6 to 18,075,155 cwt., and in 1906-7 to 20,804,457 cwt. This is

the supply that meets the foreign exports. It is drawn of course from the provinces, but is consigned direct to the ports, hence does not appear in the inter-provincial transactions. Calcutta and Bombay practically divide the traffic between them. Bombay in 1904-5 (the year with the largest imports during the past five years) took 13,986,721 cwt., of which 4 million came from the Central Provinces and Berar, $3\frac{1}{4}$ million from the United Provinces, $2\frac{1}{4}$ million from the Presidency of Bombay, $1\frac{1}{2}$ million from Rajputana and Central India, and $2\frac{1}{2}$ million cwt. from the Nizam's Dominions.

Provincial
Supply.

The traffic with Calcutta, on the other hand, amounted in the same year to 11,165,255 cwt., of which $6\frac{1}{4}$ millions came from the province of Bengal, 4 from the United Provinces, and the balance from the Central Provinces, Rajputana and Central India. The figures for 1904-5, however, were exceptionally high, and in the succeeding years were respectively—Bombay, in 1905-6, 7,289,797 cwt., and in 1906-7, 8,555,004 cwt.; and Calcutta, 6,228,115 cwt. and 6,420,501 cwt. Of the other port towns that participate in the foreign trade in oil-seeds it is hardly necessary to go into such details since the amounts are so very much smaller. Karachi, in 1904-5, drew 2,870,569 cwt.; in 1905-6, 1,826,105 cwt.; and in 1906-7, 2,972,222 cwt. almost entirely from the Panjáb, while Madras took in 1904-5, 2,868,273 cwt.; in 1905-6, 2,731,138 cwt.; and in 1906-7, 2,856,730 cwt. in the same years from its own Presidency and the Nizam's Territory.

Calcutta
Traffic.

Bombay.

Karachi.

Turning now to the returns of coastwise trade. The oil-seed traffic in 1904-5 came to 1,294,166 cwt., valued at Rs. 79,23,531 (or £528,235), and in 1905-6 to 1,552,904 cwt., valued at Rs. 1,12,35,391 (£749,026). The most significant feature may be said to be that the chief oil-seed of these returns is sesamum (*til*), 431,386 cwt. having been exchanged inter-provincially in 1905-6. Of this, Burma took 316,372 cwt., the bulk being derived from Madras. The traffic in castor is also worthy of special comment. Of the total 220,419 cwt. exchanged, 143,429 cwt. were taken by Bengal, the major portion being derived from Madras. The next most important item is the supply of castor drawn by Bombay, which in the year in question came to 51,755 cwt.

Coastwise.

Burma.

OILS.—It has already been pointed out that the Exports in oils have manifested a considerable expansion, namely, in the case of fixed oils, from a valuation of £190,333 in 1876-7 to £359,965 in 1905-6, and in 1906-7, £311,820; and in essential oils from £12,008 in 1876-7 to £47,421 in 1905-6, and in 1906-7, £54,183. But by far the most important vegetable oil (exported from India) is that of the cocoanut. The total exports of that oil during the years 1902-7 have ranged from about one to three and a quarter million gallons, or, say, a valuation of from 14 to 49 lakhs of rupees (£85,952 to £325,439). The supply goes almost exclusively from Madras, and is consigned in three nearly equal portions to the United Kingdom, Germany and the United States—the only other country of importance being Belgium. The exports of linseed oil go almost entirely from Bengal, and to a very large extent represent directly the operations of the Gourepur and other oil-mills in the neighbourhood of Calcutta. The exports are consigned chiefly to Australia and New Zealand (see p. 731).

Oils.

Foreign Exports.

Cocoanut.

Linse .

The internal traffic in oils (as manifested by the rail-borne transactions) is also interesting. Excluding kerosene, the total exports in 1906-7 came to 1,712,165 cwt. The most important is mustard and rape (726,506 cwt.), followed by "others" (638,489 cwt.); then by cocoanut (199,272 cwt.)

and by castor (147,898 cwt.). Of the traffic in mustard and rape the most significant feature may be said to be the large exports to Eastern Bengal and Assam and to Bengal proper from Calcutta. This is the direct manifestation of the oil-mills within the city, which in the year in question drew 2,353,389 cwt. of mustard and rape seed chiefly from the United Provinces to be used up in the manufacture of oil. The most significant feature of the coastwise transactions is the very large trade done in cocoanut oil. The total traffic coastwise in 1904-5 came to 8,730,737 gallons, valued at Rs. 1,25,84,419 (£838,961). Of that amount fully half was cocoanut exported from Madras into Bombay and Bengal (each taking approximately 2 million gallons), and Burma 770,000 gallons. So in 1905-6, the total traffic was 10,008,074 gallons, valued at Rs. 1,53,73,114, the exports of cocoanut being 4,612,490 gallons, valued at Rs. 70,62,430.

Cocoanut Oil
Coastwise.D. P.,
v., 463-77.
Oil-cake.

Exports.

Manure.

OIL-CAKE (Poonac).—Incidental reference has been made to the objection to exporting oil-seed, instead of expressing the oil in this country and retaining the cake. But it may be contended that the present traffic is perhaps not quite so unsatisfactory as it might at first sight be supposed. In the present state of Indian agriculture oil-cake is less in demand than in Europe, and accordingly it may be more profitable to export the seed than were the oil expressed and dependence placed on the Indian markets for the disposal of the cake. As against that contention it may be urged that the surplus cake might be exported as a regular commercial article. India is at present, in fact, doing a fairly large trade in exporting oil-cake. In 1877-8 these exports were valued at Rs. 4,30,399; in 1901-2 at Rs. 29,84,230; in 1902-3, Rs. 34,22,616; in 1903-4, Rs. 39,18,460; in 1904-5, Rs. 43,08,621; in 1905-6, Rs. 51,99,194; and in 1906-7, Rs. 35,89,740. In 1905-6 a new item, consisting of oil-cake for manure, valued at Rs. 16,99,186, appeared, and in 1906-7 this became Rs. 40,09,381. [*Cf. Mollison, Agri. Ledg.*, 1899, No. 12.]

Calcutta and
Madras.

The present traffic in oil-cake is comparatively unimportant. The total amount carried by the railways came to 1,864,415 cwt. in 1904-5; 2,182,405 cwt. in 1905-6; and 2,008,579 cwt. in 1906-7. Calcutta and Madras (the seats of the oil industry of India) are necessarily most concerned in the exports. Calcutta supplied 810,158 cwt., and Madras 637,946 cwt. The Calcutta supply went chiefly to the province of Bengal, and the Madras to its own port towns. The exports coastwise were in 1904-5 returned at 220,000 cwt. and in 1905-6, 112,005 cwt., the bulk being consigned from Madras to Bombay.

Oil-mills.

Progression.

Oil-mills.—The fact that India exports so large a quantity of oil-seeds and again imports a considerable amount of vegetable oils, has often been commented on as one of the directions of future reform. The loss to India through this circumstance may be said to be twofold:—(a) the loss of lucrative employment; (b) the loss of oil-cake that should more largely than at present be retained in India. Still it cannot be said that no progress has been made by India. In 1895 there were 163 oil-mills that gave employment to 3,368 persons, and in 1900 these had expanded to 212 mills and 5,084 employees. Recently the data of official returns have been changed: only mills that employ 25 or more persons are recorded. This has had the result of making a serious reduction in the number of oil-mills supposed to be at work. In 1903 there were by the new system 109 mills, 11 being worked by steam, with the total number of persons employed 4,985; and in 1904, 112 mills and 5,200

CANDLES AND SOAP

persons. The suburbs of Calcutta literally teem with private castor-oil mills. As manifesting their importance, it may be explained that while Calcutta exports a large amount of castor oil, practically no castor-seed leaves Bengal to foreign countries. Exports of castor-oil seed are made mainly from Bombay.

Castor Oil.

A detailed enumeration of the oil-mills of India would dispel the erroneous opinion that India is doing nothing in the direction of meeting its home markets for oils. A distinct advance has been made and is being maintained in every corner of the Empire.

CANDLE AND SOAP MAKING.—These are modern industries that are rapidly becoming of considerable importance. A striking evidence of the prosperity of the Burma candle trade may be had from the existence of an export trade in candles.

Candle-making in India.—Except in the new industry of manufacture of candles from the mineral wax and paraffin that has recently assumed considerable proportions both in Rangoon and Calcutta, India cannot be said to possess candle works of any great importance. Here and there all over the country the *batti-saz* still plies his craft of "tallow dip" making, but very few of these workers form candles by moulding. In Lahore and Bombay, candles are crudely moulded, and from time immemorial the art of rolling wax candles has been known and practised. One or two soap works have given attention to candle-making, but, as a rule, they employ mineral wax, and their candles have accordingly to be considered along with petroleum. (See Li e, p. 712.)

Candles.

Paraffin.

Wax.

While India, as a whole, is very far behind other countries in the production of candles, the demand for these articles is very considerable. Indian Imports:—The United Kingdom and Belgium are the sources of supply, and the provinces that receive these are, in sequence of demand—first Madras, next Bombay, then Bengal, and lastly Burma. The imports have fluctuated between 8 and 12 lakhs of rupees in value each year during the past twenty-five to thirty years. It may be here added that Burma has, however, begun recently to export candles, and these are of course entirely mineral. The Exports were in 1900–1 valued at Rs. 15,157; in 1901–2, at Rs. 49,703; in 1902–3, at Rs. 4,41,863; in 1903–4, at Rs. 9,05,521; in 1904–5, at Rs. 4,81,56; in 1905–6 at Rs. 16,53,646 (in which year the share of Burma was Rs. 16,37,755); and in 1906–7, Rs. 14,20,943. This traffic is mainly with China, the Straits Settlements, Ceylon, Australia and New Zealand, and is thus a new feature of India's manufacturing enterprise. (See Cocos, p. 359; Rhus, p. 914.)

Imports.

Exports.

Soap.—As already observed, to the Natives of India as a whole, soap is not of much importance, and soap substitutes (natural earths or vegetable materials), as a rule, take its place. Still, the art of soap-making has been known and practised from a remote antiquity, the impure article produced being used by the washermen and dyers. Trade statistics show, however, that India's demands on foreign countries for soap are very considerable and yearly expanding. In 1876–7 the Imports were valued at Rs. 3,32,791; in 1901–2 at Rs. 17,61,427, or an annual average expansion of 17 per cent.; in 1902–3 a still greater expansion, the imports having been then valued at Rs. 22,67,801; in 1903–4 they became Rs. 26,56,673; in 1904–5, Rs. 27,23,705; in 1905–6, Rs. 31,90,890; and in 1906–7, Rs. 32,28,156. Almost one-half the total imports are, as a rule, taken by Bombay, one-quarter by Bengal, and of the remaining quarter about one-half goes to

oap.

Imports.

Distribution.

Burma. At the same time India EXPORTS soap, though the traffic is not extensive nor very prosperous. [Cf. A. Watt, *Art of Soap-Making*, 1901; see also *Ægle ar elos* (p. 27); *Agave* (p. 35); *Alkalis* (p. 49); *Cinnamonu* (p. 313); *Cocos nucifera* (p. 359); *Fish* (p. 547); *Pinus* (p. 890); *Rosa* (p. 926); *esamum* (p. 986).]

Perfumery. **ESSENTIAL OILS AND PERFUMERY.**—This classification is convenient rather than logical. The separation between perfumes, cosmetics and condiments is often extremely difficult and even sometimes undesirable. Though most of the articles indicated may yield oils chemically, they are often used without having their oils extracted from them, just as sesamum seeds are eaten in certain Native sweetmeats, where they serve a purpose similar to the raisins and caraways in European cakes.

Imports. The IMPORTS of essential oils, essential seeds and of perfumery are of far less consequence than the exports. In 1901–2 the combined imports were valued at Rs. 5,11,456; in 1902–3 at Rs. 4,96,622; in 1903–4 at Rs. 6,56,617; in 1904–5 at Rs. 5,88,633; in 1905–6 at Rs. 5,94,433; and in 1906–7, Rs. 6,34,111. The EXPORTS were valued in 1901–2 at Rs. 22,44,404; in 1902–3 at Rs. 20,66,970; in 1903–4 at Rs. 20,71,940; in 1904–5 at Rs. 23,50,385; in 1905–6 at Rs. 29,46,855; and in 1906–7, Rs. 28,98,944. It is interesting also to observe that the exports of essential seeds have been steadily improving for some years. In 1876–7 they stood at Rs. 29,437; in 1901–2 at Rs. 14,58,241; in 1902–3 at Rs. 11,83,190; in 1903–4 at Rs. 12,32,950; in 1904–5 at Rs. 16,09,137; in 1905–6 at Rs. 20,74,818; and in 1906–7 at Rs. 19,20,257. The chief seeds exported under this heading are *Caraway* (p. 284); *Ajwan* (p. 285); *Coriander* (p. 427); *Cu* in (p. 443); *Fennel* (p. 552); *Ni er* (*Nigella*, p. 811); *Aniseed* (*Pimpinella*, p. 887); *Fenu reek* (*Trigonella*, p. 1081); and the like.

134–9.

Two Methods
of Preparation.

Jasmine.

Perfu ery is one of the most ancient and honourable of Indian crafts, and one which attains greatest importance at the present day in Northern India. It is perhaps hardly necessary to go further back than to the *Ain-i-Akbari* (Blochmann, transl. 73–89, etc.), where we read that the great Emperor encouraged and fostered the art of preparation of perfumes and scented oils. This gives the suggestion of the two methods of separating perfumes having been known from very ancient times, namely *enfleurage* and *distillation*. One of the earliest and most instructive accounts of the former, as far as India is concerned, was written by Dr. Jackson of Ghazipur, in a letter to the editor of the *Asiatic Journal* of Calcutta for June 1839 (in *Edinb. New Phil. Journ.*, 1840, xxix., 198–9). The following describes the method pursued in the preparation of jasmine. “The Natives never make use of distillation, but extract the essence by causing it to be absorbed by some of the purest oleaginous seeds, and then expressing these in a common mill, when the oil given out has all the scent of the flower which has been made use of.” Dr. Jackson gives particulars of the operation—layers of sesamum seed (see p. 986) “wetted” in water alternating with layers of jasmine flowers are covered over with a cloth and left for twelve to eighteen hours. It may be added that, according to modern European experience, jasmine is one of the perfume-yielding products that must be treated by *enfleurage*, as it does not yield its perfume in water-distillation.

Turning now to the distillation process, Hoey (*Monog. Trade and Manuf. N. Ind.*, 107–8) gives an interesting account of the *gandhi* or *itarfarosh* and his art and trade. He buys flowers from the *malis* (gardeners) and manu-

CHAY-ROOT

OLD NLAN IA
U LLATA

factures from these, by distillation, their respective perfumes. Into the still is placed the *zamin* or *mawa* of all *itar*, viz. sandal *itar*, manufactured at Kanauj. The flowers are thrown into the cauldron on the fire and their perfume comes off in steam and passes through the worm into the copper *bhapka*, and there combines with the sandal *itar*. On cooling, the perfume is separated from the water by skimming the surface. In some localities, in place of sandal, lemon-grass is used as an adjunct, especially in the production of attar of roses.

Jaunpore and Ghazipur might be described as the chief manufacturing localities, Delhi, Amritsar and Lahore the distributing centres, and Bombay the emporium of foreign transactions. The following are some of the more important ingredients and materials in Indian perfumery:—Cassie (*Acacia Farnesiana*, p. 14); ael (*Ægle Marmelos*, p. 27); Galangal (p. 60); Himalayan Dhup (*Jurinea*); Altingia (p. 61); Aquilaria (p. 72); Arachis (p. 82); Cinnamo u (pp. 315-6); Citrus (p. 327); Lemon, Rusa, Citronella Oils, etc. (pp. 451-62); Jas inum (*motiya*, *juhi*, and *chambeli*); Michelia (*champa*); i usops (*maulsari*); Lawsonia (*henna*, p. 707); Ilang-ilang (*Cananga*); Keura (*Pandanus*, pp. 188, 777); Musk (p. 786); the pikenard (p. 792); Patchouli (*Pogostemon*, p. 904); Rose Attar (p. 926); andal-wood (p. 977); ut (p. 980); Sesamum (p. 986); Vetiveria (p. 1106). [Cf. Sawer, *Odorography*, 1892; *Scient. American*, *Cycl. Receipts*, 1899, 383-5; Gildemeister and Hoffmann, *Volatile Oils*, 1900; Hooper, *The Perfumes of the Moghuls*, in *Calc. Rev.*, Oct. 1904.]

L NLAN IA U LLATA, Linn.; *Fl. Br. Ind.*, iii., 66; Prain, *Beng. Plants*, i., 559; Cooke, *Fl. Pres. Bomb.*, 1903, i., 590; RUBIACEÆ. Chay-root or Indian Madder, *chirval*, *surbuli*, *kathenyok*, *saya*, etc. A common biennial, met with from Orissa and Bengal southward to Ceylon, also in North Burma.

The root-bark, with alum as a mordant, gives a beautiful red DYE, formerly much employed in Madras for dyeing handkerchiefs (the *bandana* handkerchiefs formerly famed). Though met with in Bengal, it is not used for dyeing in that province. It is somewhat extensively cultivated in sandy situations on the Coromandel Coast, as at Nellore and Masulipatam. Previous to sowing, the land is manured, generally by penning cattle or sheep, and thereafter thoroughly ploughed. The seeds are sown in August, on the ground having been well moistened. After sowing it is again watered, and the process repeated three times daily till the young shoots appear, when water need then be given less frequently. Cow-dung should be mixed with the water once a day for the first fifteen days. Extensive watering is the chief feature of the cultivation, but weeding has also to be constantly performed. The expense of cultivating an acre is naturally heavy (estimated at Rs. 28-7a.) compared with the returns.

Only the bark of the root contains the dye. The Natives consider the roots of the wild plant best, and prefer to make their collections at the end of the second year's growth. In dyeing, the Hindus use an aqueous solution of the colouring matter, obtained by pounding the root in water. The fabric is steeped several times in this solution, then boiled for two hours in a similar solution and finally washed with clean water and dried. Various attempts have been made to introduce the dye into Europe, but these have been unsuccessful, due probably to the fact that the root rapidly deteriorates when stored in damp situations. The tinctorial properties of the dye-stuff have been investigated by Hummel and Perkin. [Cf. Alexander Hamilton, *New Acc. E. Ind.*, 1727, i., 370; Milburn, *Or. Comm.*, 1813, i., 277; Heyne, *Tracts on Ind.*, 1814, 209; *Pharmacog. Ind.*, 1891, ii., 199; Hummel and Perkin, in *Proc. Chem. Soc.*, 1893, 201; 1895, 150; Holder, *Monog. Dyes and Dyeing, Madr*, 1896, 2; *Imp. Inst. Tech. Repts.*, 1903, 207-9; Joret, *Les Pl. dans L'Antiq.*, etc., 1904, ii., 349.]

OPUNTIA ILL NII

THE PRICKLY PEAR

D.E.P.,
v., 493-6.
Turpeth.

OP RULINA TURP THUM, Manso; Prain, *Beng. Plants*, 1903, ii., 731; Cooke, *Fl. Pres. Bomb.*, 1905, ii., pt. ii., 240; *Ipomœa Turpethum*, *Fl. Br. Ind.*, iv., 212; Talbot, *List Trees, etc.*, 1902, 251; *Rec. Bot. Surv. Ind.*, 1904, iii., 81. **CONVOLVULACEÆ.** Turpeth Root or Indian Jalap, *nisoth, teori, tohri, chita bānsa, nisottar, tikuri, shivadai*, etc. Found throughout India, ascending the hills to altitudes of 3,000 feet; occasionally cultivated as an ornamental plant.

Medicine.

The root (also root-bark), known as *trivrit*, has been used as a purgative, by Native practitioners, from time immemorial. Varthéma (*Travels*, 1510, (ed. Hakl. Soc.), 106-7) mentions it by the name of *turbidi* among the spices of Cambay, and Garcia de Orta (1563, *Coll.*, liv.; also in Ball, *Proc. Roy. Ir. Acad.*, 1889-91, 3rd ser., i., 677) gives an account of the plant and the uses made of it. Two varieties have been described by most writers, *sveta* or white, and *krishna* or black. The white is preferred, as the black is considered too drastic. As sold in the bazárs, Turpeth consists of the root and stem of the plant cut into portions of about one-half to two inches in length. The market rate is about $\frac{1}{4}$ to 1 anna per lb. [Cf. Forster, *Pl. Esc.*, 1786, 77; Milburn, *Or. Comm.*, 1813, i., 293; Paulus *Egineta* (Adams, Comment.), 1847, iii., 445-6; *Pharmacog. Ind.*, 1891, ii., 527-30; Dutt, *Mat. Med. Hind.*, 1900, 203-4.]

Two Forms.

D.E.P.,
v., 490-2.
Prickly
Pear.

OPUNTIA, Mill.; *Fl. Br. Ind.*, ii., 657; Gamble, *Man. Ind. Timbs.*, 1902, 382-3; Talbot, *List Trees, etc.*, 1902, 180; Prain, *Beng. Plants*, 1903, i., 531; **CACTEÆ.** Several species have been introduced into India and are now quite naturalised. In many portions of the hotter regions, such as in Madras, Bengal, the United Provinces and the Panjáb, they have overrun immense tracts of country, and their eradication has in some cases become a serious problem. For their connection with the Cochineal insect, see *Coccus cacti* (p. 348).

Naturalised
Plant.

. illenii, Haw. The Prickly Pear, *nág-phaná, pheni-mama, samar, zhor-hatheylo, nága-dali, chappal, sha soung, lit wa*, etc. This is the only species described in the *Flora of British India*. It is indigenous in America, but naturalised all over India from Bengal and Madras to the Panjáb, and found on the Himalaya up to 5,000 feet in altitude. The fruit is edible, and can be employed in the distillation of alcohol. The jointed, juicy, leaf-like stems, when deprived of their spines, have generally been considered a useful **CATTLE FOOD**, especially in times of famine. Mr. P. R. Mehta, however, in a report on prickly-pear feeding experiments carried on at the Poona and Surat Farms, gives a poor estimate of its feeding value. He states that the experiments conclusively prove that the prickly pear has hardly any value as a cattle food. A sample analysed by Leather gave the following result:—water, 16·96 per cent.; organic matter, 60·64; ash, 22·40. Hooper furnishes the following composition of the fruit from Nellore examined by him:—carbohydrates 41·89; fibre 32·00; albuminoids 6·25; fat 3·63; water 5·67; and ash 10·56; (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1904-5, 30).

Hedges.

In India the plant is much used to form hedges about fields and for fences round homesteads. Gamble states that the chief interest in *Opuntia*, to the Forest Officer, has been in the hope that it would assist in the reproduction of forest trees, by protecting the young seedlings from cattle. A coarse **FIBRE** can be obtained from it, which might prove useful as a paper material. [Cf. Mason, *Burma and its People* (ed. Theobald), 1883, ii., 441; De Candolle, *Orig. Cult. Plants*, 1884, 274; Asa Gray, *Scient. Papers*, 1889, i., 312; *Kew Bull.*, 1888, 165-73; *Pharmacog. Ind.*, 1890, ii., 99; *The Scrub Exterminator, Agri. Dept. Madras Bull.*, 1891, 23; Voelcker, *Improv. Ind. Agri.*, 1893, 193-4; Bourne, *Rept. on Destruct. of Prickly Pear by Cochineal Insect, Offic. Govt. of Madras Rev.*, Aug. 5, 1897; Dodge, *Useful Fibre Plants of the World*, 1897, 253; Maiden, *Study of Prickly Pears Naturalised in New S. Wales*, *Dept. Agri. Sydney, Misc.*, 1898, 253; Woodrow, *Gard. in Ind.*, 1899, 336-7; Mehta, *Prickly Pear and Aloe as Cattle Fodder during Scarcity*, in *Dept. Land Rec. and Agri. Bomb. Bull.*, 1903, No. 22.]

Fibre.

ORY A, Linn.; *Fl. Br. Ind.*, vii., 92-4; Matthioli, *Comm. on Dioscorides*, 1565, i., 401-3, and t.; Rumphius, *Herb. Amb.*, v., 196-201; Duthie and Fuller, *Field and Garden Crops*, 1882, i., 15-20, t. iv.; Duthie, *Fodd. Grass. N. Ind.*, 1888, 20; Lisboa, *Bomb. Grass.*, 1896, 37-8; Heuzé, *Les Pl. Aliment. des Pays Chauds*, 1899, 14-116; Semler, *Trop. Agrik.*, 1903, iii., 1-48; Prain, *Beng. Plants*, 1903, ii., 1184; GRAMINEÆ.

While botanical writers have described some twenty species of the genus *Oryza*, Bentham and Hooker (*Gen. Pl.*, iii., pt. ii., 1117) say that scarcely five of these can be easily distinguished and even these are very generally viewed as varieties of but one species, *O. sativa*, Linn. The chief forms are met with in the East Indies, though some are indigenous to Australia and most have been widely cultivated from ancient times in the warmer regions of both hemispheres.

Species and Varieties.—There may be said to be four fairly easily recognised forms of *Oryza* in India:—

Oryza coarctata, Roxb., *Fl. Ind.*, ii., 206; *O. triticoides*, Griffiths, *Notulæ Pl. Asiat.*, 1851, pt. iii., 8; *Icon.*, t. 142; Prain, l.c.; *Fl. Br. Ind.*, vii., 93. It is known as *nanoi* (Indus valley), *natsaba* (in Burma); *maniklal* (the plant), and *barirdhan* (the grain) in Patuakhali, Dacca.

Distribution.

Indus
Valley
Wild Rice.

In this grass the margins of the leaves are spinose-serrate. It frequents the margins of rivers and is essentially an aquatic plant. Griffith had grave doubts as to the propriety of treating it as a species of *Oryza*, and suggested the genus *Sclerophyllum*. Roxburgh gives the delta of the Ganges as its habitat, and says it was first discovered there by Buchanan-Hamilton in 1796. He then adds that he had failed to find that the plant was put to any economic use or to discover an Asiatic name for it.

In 1895 Mr. J. E. O'Connor (at that time Director-General of Statistics) proposed to have all the articles of official returns that appeared under "Others" investigated. He undertook to have specimens sent to me for determination. Almost the first, under edible substances, that came to hand was a cereal from Karachi. This was stated to be a wild grain collected from the swampy margins of the Indus and carried all over India to be eaten by the Hindus during certain ceremonial occasions. At first sight it looked like a form of wheat, but Sir George King and Lieut.-Col. D. Prain, who kindly examined it with me, suggested that it most probably would prove a form of rice. Botanical specimens came to hand in June 1895, and were at once seen to be the long-lost species *O. coarctata*, Roxb., which, because of its resemblance to wheat, had also been called *O. triticoides*. Through subsequent investigations this interesting plant was found prevalent in the Indus valley; nowhere in the river basins of South India; occasional in the Sundribans (Saugor Island) and the lower Gangetic basin; and common near Khaton and Moulmein in Burma. It seems probable, however, that the resemblance of the grass to wheat may have originated the belief that wheat was indigenous to the Indus basin. Thus, for example, De Candolle (*Orig. Cult. Plants*, 356) while discussing the origin of wheat, observes that "Strabo (ed. 1707, ii., 1017), born 50 B.C., says that, according to Aristobolus, a grain very similar to wheat grew wild upon the banks of the Indus on the 25th parallel of latitude." And it is certainly remarkable that until the discoveries briefly narrated above, the wild rice of the Indus should have remained unknown to the botanical world while it was actually being traded in all over India.

Rediscovery.

Distribution.

Simulates Wheat.

Samples of the *nanoi* rice were sent to Church (*Food-Grains of India*, suppl., 1907, 5) for chemical examination, and the result showed that it is by no means an unwholesome article of food, though the edible portion, relatively to the husk and fibre, is exceptionally low. The nutrient ratio was found to be 1 : 7.6, while the nutrient value worked out at 84.9.

Che ' try.

anula, Nees. A species found on dry soils at altitudes up to 3,000 feet. Specimens have been collected from Sikkim, Assam, Burma, Bengal (Parishath and Rájmahál hills), Malabar and Courtallum. It is perennial with almost woody root-stock and thin, round, firm, branching stems. The surface of the inner glume, though glabrous, is rendered woolly-looking through the presence of irregular roundish granulation.

Wild ill
Rice.

Assam and
urma
Wild Rice.

. *latifolia*, Desv., *Journ. Bot.*, 1813, i., 77; *O. officinalis*, Wall. A tall, sparsely branched species with very broad multi-nerved leaves and profuse (almost umbellately) branched panicles: surface of inner glume composed of parallel bands of squarish corrugations. The area of distribution, from the records of its collection, may be given as from Sikkim and the Khasia hills, Assam (Gowhatty), to Burma (Pegu and Arakan). It is in Akyab known as *daung-saba*, and in Mergui as *natsaba*.

Cultivated
Rice.

O. sativa, Linn. The Cultivated Rice, *dhan*, *chával*, *uri*, *sáthi*, *munji*, *shali*, *garri*, *dángar*, *bhatta*, *tandula*, *arishi*, *nellú*, *biyam*, *akki*, *saba*, etc. Cultivated throughout India, but often met with also wild (or at all events feral) wherever marshy land occurs in tropical regions. The chief area of the Indian wild forms may be given as from Madras and Orissa to Bengal, Chittagong, Arakan and Cochin-China. Roxburgh was so satisfied that the wild stock was the parent of the cultivated that he described it alone, and gave only a few of the chief features of the cultivated forms known to him. Though the task of separating the wild and cultivated states into varieties or races is by no means easy, the wild forms examined by me may be here briefly indicated:—

Red-coloured
Rices.

Var. α rufipogon. This seems to correspond to the plant of that name described by Griffith. No specimen of Griffith's plant is known to exist, but it is probably the source of the red-coloured rices of India.

Tank Rice.

Var. β fatua; Prain, *Beng. Plants*, ii., 1184. This is apparently the plant that I distinguished in the *Dictionary as bengalensis*. Under this come by far the major portion of the submerged rices. It is the type most commonly spoken of, moreover, as "Wild Rice," being found on the margins of tanks (*jhils*) or frequently deeply submerged fields in Bengal, Madras and Burma. Its most general name is *uri* or *jhara*, but from Madras have come samples under the names *nirvari* or *nivari*, and from Burma *daung-saba*, *daik-saba*, *nat-saba* and *pago-shwe-hmat*, names often also given to *O. latifolia*. Wild rice is met with both bearded and beardless, as also red, white or almost black in colour. In fact, the grains of the wild and cultivated plants cannot be distinguished except perhaps by the cultivators, who in this matter seem to possess an intuitive knowledge. C. B. Clarke said, "I do not know how, in the young state, the cultivator tells the *uri* from the *aman*. I cannot."

"Double Rices."

Var. γ plena. This is given by Prain to include the "Double Rices." A cultivated rice exists in Chittagong with from 2 to 7 ovaries.

Hill Rice.

Var. δ abuensis. Probably the most temperate form of wild *O. sativa* as yet collected. It is a much smaller plant than the prevalent wild form (β), and may be the source of many of the best qualities of awnless *chotan aman* or *rowa* rices of Bengal and of the superior qualities of Upper India, Madras and the hills generally. This is probably the plant of which there was a good deal written some short time ago under the name of "Hill Rice."

Early and Late
Rices.

The names thus suggested for the above four forms of wild *O. sativa* are purely provisional, since the classification by no means provides a place for all the distinctive forms of the cultivated plant. Roxburgh adopted what is perhaps the most convenient classification of the latter, viz. a system based on their peculiarities of cultivation, the *early* and the *late* rices. He specialises sixteen forms. The late rices are the "great crop." Of these, he mentions eight all of which are awnless and afford, when cleaned, *white grains*. Of early rices, four are awned and yield red or coloured grains: one is awned but yields a white grain, while three are awnless and afford white grains. Of the late rices, four have coloured and four white husks; of the early, six have coloured husks, two are white or pale. The general conclusion to be drawn from an analysis of Roxburgh's cultivated rices shows that the progression in value is from the awned to the awnless forms, and from the coloured to the colourless.

Progression of
Awned to
Awnless

D. P.,
v., 51-9.

istory.—Writers are agreed that the earliest mention of rice cultivation is connected with China, where, according to Stanislas Julien, a ceremony was established in 2800 B.C. by Emperor Chin-nung, in which the sowing of five kinds of grain, one being rice, is the chief observance. This, together with the well-known adaptability of large portions of China to rice cultivation, led De Candolle to presume the plant may have been a native of that country. He does not,

however, restrict its wild habitat to China, but admits it has been found both in India and Australia under such conditions as to allow of little doubt that it is native to these countries as well. De Candolle simply affirms that rice cultivation in India, though subsequent to that of China, has been a valued crop since the classic period. It is pointed out in the *Dictionary* that in spite of the temptation to derive the Arabic (*al-ruzz*, *aruzz*, *uruzz*, *wiz*, etc.), Greek (*ῥυζα*) and European names (*rice*, *riso*, *riz*, etc.) from the Tamil *arisi*, modern philologists are agreed that they cannot be so derived, but come from the old Persian word *virinzi* or *virinza*, the modern equivalent of which is *birinj*. Sir C. J. Lyall states (*D.E.P.*, l.c. 518) that *virinzi* is exactly the equivalent we should expect of the Sanskrit word for rice, *vrihi*, and the names point to the time when the two branches of the Aryan race dwelt together and developed the respective peculiarities of their languages from a common or original tongue. The Persians did not borrow the cultivation of rice from the Indians; the plant existed in the region where the two races dwelt together before their respective migrations. In other words, there is no evidence to show that its cultivation in Southern Asia was not so ancient as to have allowed of its diffusion into the Aryan home at a period prior to the division of that branch of the human family. The chief objection to this hypothesis, viz. the absence of any pointed allusion to so valuable a plant in the earliest *Vedas*, is not serious, since a pastoral people, like the early Aryan invaders, may not have appreciated its importance till they settled down and took to agricultural pursuits. Perhaps the oldest actual samples of rice are those collected by Stein at Kara-dong (*Ancient Khotan*, 1907, 448). These would appear to have been engulfed by sand about the close of the 8th century. Then, approximately in the same part of Eastern Turkestan, was found *The Bower Manuscript* (Hoernle, transl., 123-4), believed to date from about the 5th century. In that work frequent mention is made of "fried paddy" in the production of a drug used in the cure of coughs.

It may be repeated, however, that the chief wild habitat of the plant to-day is roughly from Southern India to Cochinchina—we have no record of its existence as a wild plant in Turkestan or anywhere in Central Asia. But in passing, it may be added that the habitat of the wild plant in India coincides with the region through which the Dravidian invaders passed till they culminated in the Tamil civilisation. Cultivation appears, in fact, to have spread eastwards to China perhaps three thousand years before the Christian era, and, at perhaps a slightly more recent date, westwards and northwards throughout India to Persia, Central Asia, Arabia, and ultimately to Egypt and Europe. An early record of the exports of rice from India is the passage in the *Erythrean Sea* (ed. McCrindle, 113). This may be put at 60 A.D., and refers to Gujarat. [*Cf. Acc. Ind. and China by Moh. Trav. in 9th Cent.* (Renaudot, transl.), 1733, 13; Vertomannus, *Travels*, 1503, in *Hakl. Voy.*, iv., 1811, 577; *Ain-i-Akbari*, 1590, (Jarrett, transl.), ii., 121, 350; Pyrard, *Voy. E. Ind.*, 1601 (ed. Hakl. Soc.), i., 326-7, etc.; Jahangir, *Memoirs* (Price, transl.), 1829, 98; Mandelslo, *Voy. E. Ind.*, in Olearius, *Hist. Muscovy*, etc., 1662, 62, 86; Fryer, *New Acc. E. Ind. and Pers.*, 1675, 119; Tavernier, *Travels* (ed. Ball), 1676, i., 282, 391, etc.; Herbert, *Travels*, 1677, 310 and t.; Alexander Hamilton, *New Acc. E. PROPERTIES AND USES.—The grain of rice is one of the chief articles of human food throughout India, while in many parts (e.g. Manipur) it was in 1882 one of the chief foods given to horses and even to cattle, and throughout India the straw of the better qualities is invariably collected, cut into small pieces and given to cattle, along with several flavouring liquid preparations, oil-cake or grain, designated the currie stuffs. The chaff and waste obtained in winnowing and husking also constitute important articles of human and cattle food. But husking is a troublesome process. In India a large part of the rice sold in shops and exported to Europe as an article of human food has been prepared by being first half boiled, then dried in the sun, and finally husked by the ordinary pestle and mortar. Such rice is, in trade, termed "par-boiled." Husking without boiling is a tedious process when done by hand. In Yarkand there is a mechanical contrivance for husking rice in which water is the motive power. In the plains of India, rice is frequently husked by the same appliance as is used in pounding bricks. A pestle suspended from the end of a beam, worked by the foot, is made to fall with considerable force on the grain. A woman, standing at

the further end of the heavy beam, alternately rests and removes her weight from its extremity, thus causing the pestle to rise, then fall on the rice, while a second person attends to the grain, sweeping it into a little mound under the stroke of the pestle.

The preparations of rice made in India are very numerous. Dutt (*Mat. Med. Hind.*, 1900, 268-9) gives the vernacular names of various medicinal ones and their properties. Their use in brewing and distilling is, in India, almost universal. SPIRITS from rice (*sura*) are alluded to by Linschoten as having been largely consumed in Southern and Western India three hundred years ago, while *sura* is frequently mentioned in the *Institutes of Manu*—a work written (the earlier portions of it, at least) some fifteen hundred years ago. At the present day a kind of beer (*pachwai*) made from rice is extensively consumed. [*Cf. Ray, Hindu Method of Manuf. Spirit from Rice, in Journ. As. Soc. Beng.*, n.s., 1906, ii., No. 4, 129-42.] See Malt Liquors (pp. 757, 760), Spirits (pp. 1043, 1045, 1046), and Vinegar (p. 1111).

The properties and uses of rice are, in fact, extremely varied, and to the people of India an infinity of forms, many of which have each some special merit. A DYE is made from the husk, and the straw (even the stubble and roots) may be used in paper-making. (For BASKETS, see p. 116; MATS, p. 776.) As an edible grain there may be said to be three chief grades—the finer qualities or table (Patna) rice: the lower grades suitable for distillation or for the manufacture of starch (Blount and Bloxam, *Chem. for Engin. and Manuf.*, 1900, 186). The rices of Burma are employed for distillation (and for that purpose very largely go to Holland and Germany) and for conversion into starch (mainly to England). They are thick, coarse, highly glutinous rices, and when boiled assume a heavy, somewhat repulsive appearance to persons not accustomed to them. Such glutinous rices are, however, much prized in the manufacture of CEMENTS. A special Indian cement is made from the water in which rice has been boiled, mixed with a small quantity of pure lime (see p. 293). Black Burmese rice (*Kew. Bull.*, 1892, 232-4) may be spoken of as an exceptionally glutinous grain.

Leather (*Agri. Ledg.*, 1903, No. 7, 175-8) gives the following chemical analysis of rice: *Undecorticated* (fine sorts):—moisture, 12.55 per cent.; oil, 2.14; albuminoids, 6.35; soluble carbohydrates, 65.29; woody fibre, 7.84; soluble mineral matter, 1.39; sand and silica, 4.44; total nitrogen, 1.09; albuminoid nitrogen, 1.01. *Decorticated* (fine sorts):—moisture, 12.25 per cent.; oil, .92; albuminoids, 6.45; soluble carbohydrates, 78.83; woody fibre, .21; soluble mineral matter, .82; sand and silica, .51; total nitrogen, 1.19; albuminoid nitrogen, 1.03. Further analyses of coarser kinds of rice, rice husks, bran and straw, will be found in the same article. Following up these results, Hooper (*Rept. Labor. Ind. Mus. (Indust. Sec.)*, 1906-7, 11) gives particulars of the comparative nutritive value and glutinosity of some of the chief kinds of rice. Certain forms were found to be more nutritious than previous analyses would indicate. Hanausek (*Micro. Tech. Prod.* (Winton and Barber, transl.), 1907, 42) gives interesting particulars of rice-grains as seen under the microscope. [*Cf. Church, Food-Grains of Ind.*, 1886, 66; Dodge, *Useful Fibre Plants of the World*, 1897, 254; Browne, *Prop. and Util. of Rice Oil in Louisiana, Planter and Sugar Manufacturer*, 1905, xxxiv., 352-3; *Excise Admin. Repts. Beng., Burma*, etc.]

CULTIVATION.

Tropical
Agricul-
ture.

Rice "is essentially a crop of damp tropical or semi-tropical climates. The finest varieties and the largest yields are produced in tracts which, during the growing season, afford a moderate degree of sunshine and a damp, warm atmosphere. Rice is therefore the staple crop of all areas of heavy and assured rainfall; but good crops are produced in districts which receive moderate or even light rain, when this can be assisted by sufficient irrigation."

"Rice is sown in three ways—broadcast, by drill and by transplanta- tion from a seed-bed where it has been broadcast sown. As a rule, the first method is practised on inferior soils, or where labour is scarce. Rice is drilled in some districts of Bombay, but this system is not common. The third method is much more usual than the others and is less risky. Broadcast or drilled rice requires 80 to 120 lb. of seed per acre, while the seed-rate of the transplanted crop varies from 30 to 80 lb. per acre."

AREA UNDER THE CROP

**ORY A
ATIVA
Cultivation
Bengal**

“The yield in different tracts, from different soils, and from different methods of cultivation varies very greatly. In good soil an average transplanted crop yields probably about 2,400 lb. of paddy per acre in a favourable season. Broadcast and drilled rice yield much less” (*Imp. Gaz. Ind.*, 1905, iii., 26-9).

In recent agricultural statistics it is shown that the net area cropped in British India amounted, in 1905-6, to 207,683,741 acres. Of this, 73,400,522 acres were found to be under rice. In the Native States in the same year the net area cropped amounted to 12,015,009 acres, and the area under rice to 717,767 acres. Thus, out of a total area of 219,698,750 acres under crops, rice occupied 74,118,289 acres, or over one-third. But so large a percentage averaged for the whole of India is misleading. Rice is almost concentrated into Bengal. In fact, with the exception of Madras and Burma it is in the other provinces of India unimportant relatively. In the *Agricultural Statistics* (published by the Government of India) two sets of figures are given, viz. (a) the surveyed areas from which we obtain the total rice area of 73,400,522 acres; (b) estimates of area and yield framed by the local authorities (township officers, etc.). In the case of Burma, the local estimates are usually considerably below the surveyed areas (in fact, they do not deal with the whole of the province), but these estimates are instructive. The following are the figures (estimated) of the four chief rice areas for 1905-6:—Bengal, 25,150,600 acres; Eastern Bengal and Assam, 15,960,200 acres; Madras, 6,604,400 acres; Burma, 6,713,400 acres; giving a total of 54,428,600 acres and a yield of 433,138,300 cwt., and in 1906-7 a total of 54,521,600 acres and 430,258,000 cwt. In the case of Burma the surveyed area was 9,283,801 acres. The *Final General Memorandum*, issued by the Commercial Intelligence Department, estimates the total area in the four chief centres of production as having been in 1905-6, 54,428,600 acres, and the yield as 375,198,300 cwt. of cleaned rice; and in 1906-7, 54,535,400 acres and 368,334,000 cwt.

Estimated Total
Areas and
Yields.

Bengal (excluding Eastern Bengal and Assa).—*Area*.—The normal area cultivated with rice in the province of Bengal (according to the *Season and Crop Report* for 1905-6) has been estimated at 26,308,800 acres, and as the total area in Bengal under cultivation in that year amounted to 45,287,000 acres, it is thus seen that rice comprised over 58 per cent. of the actual cropped area of the province. The *Final General Memorandum* for 1906-7 stated the *estimated area* in Bengal as 24,506,200 acres, and the yield as 195,461,600 cwt. of cleaned rice. This represented 34·8 per cent. of the rice area of British India. The *Season and Crop Report* for 1906-7 gives the *normal area* as 25,919,600 acres, which would consist of 21,301,700 acres of winter rice and 4,617,900 acres of autumn rice. The forecast of the winter rice alone for 1905-6 shows a total of 20,043,400 acres, which represented 28·5 per cent. of the total area under this particular crop in British India. The corresponding estimate for 1906-7 was 19,845,300 acres of winter rice. The chief districts in 1905-6 were:—Midnapur, 1,365,300 acres; Ranchi, 1,240,900 acres; Gaya, 1,151,600 acres; Shahabad, 1,132,000 acres; Darbhanga, 961,400 acres; Cuttack, 952,200 acres; Hazaribagh, 950,400 acres; Manbhum, 929,100 acres; and Bardwan, 807,700 acres.

16,105,800 acres as compared with 15,960,200 acres in the previous year. The total yield came to 122,476,700 cwt. This represents 23 per cent. of the total rice crop of India. The forecast of the winter rice for 1905-6 shows 12,226,200 acres, which represented 17·2 per cent. of the winter rice for the whole of British India. The chief districts were as follows :—Bakarganj, 1,436,900 acres ; Dinajpur, 1,160,000 acres ; Maimensingh, 1,130,000 acres ; Sylhet, 1,098,400 acres ; Rangpur, 837,900 acres ; Rajshahi, 636,900 acres ; and Tippera, 614,300 acres.

Races.

Races Cultivated.—There are innumerable varieties of rice familiar to cultivators under various names, and possessing particular properties which make their cultivation suitable to particular localities. In the two provinces of Bengal, they may all be referred to three primary classes, according to the land on which they are grown, the season of year when reaped, and the period taken in coming to maturity. Thus :—
Á n. (1) The *áman* (or winter rice) crop, sown on low lands in May or June and reaped in December or January. This is by far the most important crop. (2) The *áus* or *bhadoi* (in official statistics designated as autumn rice), or early rice crop, sown in April or May on comparatively high land and reaped in August or September. (3) The *boro* (or summer rice) crop, sown in swamps in January or February and reaped in April or May.

Three Groups.

Á n.

Áus.

Boro.

Two Crops.

An important feature of the Bengal rice crop is the fact that a large portion of the area bears two or more crops a year, a circumstance that has led to the expression of a “vertical” as compared with a “horizontal” area. In fact, it has been pointed out that a proprietor of an estate with a fairly mixed soil might have three, four, or even five harvests of rice every twelve months :—(1) *áus*, from July to August ; (2) *chotan áman*, from October to November ; (3) *boran áman*, from December to January ; (4) *boro*, from April to May ; and (5) *raida*, from September to October.

Five Crops.

Multiplicity
of Fo

It has also been said that in many parts of Bengal two crops are all but universal, hence it may be inferred how misleading a hard-and-fast percentage of rice area may be to the total cropped area. In the Indian Museum will be found a collection of rices made in 1872 and for some years subsequently. The collection finally brought together came to something like 5,000 forms. These are probably not all distinct, but even if halved, the number would still be sufficiently significant of the vast antiquity of the cultivation. A remarkable fact is that the *áus*, *áman*, and *boro* rices of one district are often so different from those of another, that if interchanged the one may not grow on the fields where the other has flourished for centuries. Here the European farmer is confronted with a problem scarcely known to scientific agriculture ; for the rice-cultivator of India will detect the one from the other with a perfectly marvellous degree of certainty. In Burma a few forms only constitute the chief crop, and to these the milling apparatus now in use have been adapted, and to such an extent that it is believed the Burma machinery would be quite unsuited to Bengal, and, further, that milling in Bengal on the European method would be impossible, unless a particular rice could be guaranteed in sufficient quantity to justify the preparation of the required special machinery.

Cultiva-
tion in
Dacca.

A. C. Sen gives an instructive account of the methods of cultivation in the Dacca district, and as that is more or less applicable to the whole of Bengal, as well as to Eastern Bengal and Assam, it may serve the purposes of this work better than a series of abstracts of the varying methods

in many districts. He divides the crops into three groups, subdividing each again into two sections. These are (1) *áman*, (a) long-stemmed and (b) transplanted; (2) *áus*, (a) ordinary and (b) *lepi*; (3) *boro*, (a) ordinary and (b) *lepi*.

ÁMAN.—Long-stemmed *áman* is extensively grown in Dacca. Low lands, the sides of *jhils*, and low plains on which 5 to 15 feet of water accumulate during the rains, are selected. The soil best suited is a stiff clay, deposited on the bottom and edges of *jhils*. At harvest-time only the ears with about 1½ feet of the straw are removed. The remainder of the straw is generally gathered in heaps and burnt, and immediately after the field is ploughed, generally in December. It is again ploughed once or twice and left exposed till March–April, when the larger clods are broken. One or two more ploughings and harrowings are given, and the field is ready for sowing in April–May. About 15 seers of seed are broadcasted over a *bigha* of land. In moist low-lying places, sowing takes place a month or even two months earlier, in February–March. Harvest is from 15th November to 15th January. When the seeds have germinated the field is rolled twice with the ladder, and when the plants are 5 to 6 inches high the soil is loosened by the rake. After this the only operation till harvest is a weeding, which may be dispensed with. The yield per *bigha* varies from 3 to 12 maunds.

Transplanted *áman* is grown on two different classes of land, in the upper reaches of the valleys of the Madhapur jungle and in the comparatively high land and old *dearaks* of the Brahmaputra and its branches. The *paddy* in the Madhapur valley is a special variety, known as *shaldan*; the transplanted paddy of other places goes by the general name of *rowa*. Seedlings are prepared in a nursery close to the *rayiat's* homestead, or in a corner of the field. The nursery is ploughed four or five times in April–May, and the next month, when a little rain-water has collected on it, the surface is levelled and plastered. Meanwhile the necessary quantity of seed (6 seers for every *bigha*) is soaked in an earthen pot, drained, and kept covered with mats till it germinates; then it is sown broadcast so thickly that the grains overlap. When the seedlings are 12 to 18 inches high, they are fit for transplantation. In the case of jungle valleys, the first thing done before transplanting is to repair the embankments thrown across for collecting water. The field is prepared by ploughing in the mud two or three times. The seedlings are transplanted at the end of July about half a cubit apart either way, putting in three to four plants in the same place. The crop is harvested in November–December. In the case of *dearakh* land, two ploughings are given in the dry field, as soon as the previous crop, generally *khesari*, is taken off. On such lands two rain-crops are sometimes grown in the same field in the same season. As early as possible the field is sown with jute or *aus* paddy. The jute or the paddy is harvested in July–August; then the field is ploughed and transplanted with the *áman* crop.

ÁUS.—This kind of paddy is grown (1) on the high grounds of the Madhapur jungle, where sufficient water cannot be collected for the cultivation of *shal* paddy; (2) on the comparatively high and sandy *dearakh* lands. *Áus* paddy cannot be grown on land on which more than 2 feet of water accumulates during the early part of the rains. The land on which *áus* paddy grows is light and easily workable. It generally bears two crops in the year—*áus* paddy or jute during the rains and one

Seasons.	of the pulses or mustard during the cold weather. As soon as the <i>rabi</i> crop is off the field, it is ploughed and harrowed as rapidly as possible. Preparation must be hastened, especially on <i>char</i> lands, for here a late crop is sure to be lost by the rise of the rivers. Sowing time, therefore, varies. In the <i>chars</i> of Meghna, it may be sown as early as the middle of February; in the highlands of North Manikgunge it may be delayed till the middle of April. As soon as the plants appear the field is rolled with the ladder, and a week after harrowed with the rake. After this it must be carefully weeded. Harvest extends from the middle of July to the middle of August.
Harvest.	
Boro.	<i>BORO</i> .—The places in Dacca where this class of paddy is most extensively grown are (1) the sides of the <i>jhils</i> and streams of the Madhapur jungle; (2) the <i>chars</i> and edges of the Meghna and its branches; (3) in some of the <i>chars</i> of the Padma. The soil best suited is a mixture of clay and vegetable matter. As soon as the rains are over, a plot, from which the inundation water has just receded, is chosen for a nursery, aquatic grasses, etc., are removed, and the place worked into a soft mud. The seed is made to germinate and then sown broadcast. Thirty seers of paddy sown on a quarter <i>bigha</i> of land give seedlings sufficient for transplanting two <i>bighas</i> . The time for sowing is usually about the middle of October, and for transplanting, December-January. No tillage is generally needed for <i>boro</i> paddy. The harvest time is April-May and the yield per <i>bigha</i> 5 to 12 maunds.
Soils.	
Seed.	
Harvest.	
Lepi.	In some of the islands of the Padma, large areas of land may be seen on the same level with the water at low tide covered by a soft and deep mud. The <i>raiya</i> s have discovered a method of cultivating paddy on these known as <i>lepi</i> . All that is done is to sow the seed broadcast and plaster (<i>lepa</i>) the mud over it. Before sowing the seed, it receives the same treatment as described above for <i>boro</i> and <i>rowa</i> paddy. [Cf. C. B. Clarke, <i>Kew Bull.</i> , 1888, 284-91; Sen, <i>Rept. Agri. Stat. Dacca</i> , 1889, 28-33; <i>Cult. and Prep. of Rice in Beng.</i> , <i>Journ. Agri.-Hort. Soc. Ind.</i> , 1890, viii., 397-405; Basu, <i>Agri. Lohardaga</i> , 1890, pt. 1, 54-63; 1890, pt. 2, 26-8; Banerjee, <i>Agri. Cuttack</i> , 1893, 64-74; <i>Admin. Rept. Beng.</i> , 1901-2, 12-4; Roy, <i>Crops of Beng.</i> , 1906, 1-29; Maxwell-Lefroy, <i>Rice Bug, Mem. Dept. Agri. Ind.</i> , 1908, ii., 1-13.]
Assa .	<i>Assa</i> .—By way of affording a comparison with the particulars already given regarding Bengal as a whole, the following brief statement of the Assam Valley may be furnished. Darrah (<i>Ann. Rept.</i> , 1887-8) discussed the Assam rices under two sections which practically correspond with the chief Bengal crops, viz. early or summer, and late or winter rices. He subdivided these into the two great sections of the province, the Brahmaputra valley—Assam—and the Surma valley—Sylhet and Cachar. Of the rices of the Brahmaputra valley, he enumerates three— <i>sali</i> , <i>ahu</i> , <i>bao</i> . <i>Sali</i> is the general term applied to all transplanted rice grown on land lower than that required for <i>ahu</i> and higher than needed for <i>bao</i> . It is sown about May and June, transplanted in July and August, and reaped in December and January. <i>Ahu</i> is the name given to the numerous kinds of rice which grow on high lands, require little rain, and are sown from March to June and reaped June to September. It is usually sown broadcast, but sometimes transplanted. <i>Bao</i> comprises the varieties grown on the lowest land which will support rice. It is sown in March-April, cut in November-December. When transplanted, the operation is performed in July and August. Of the Sylhet or Surma valley, there are
Summer and Winter Rices.	
Seasons.	
Ahu.	
Bao.	

low-land and high-land *áus*, *murali*, *sáil*, low-land and high-land *áman*, *kataria* and *sáil bura*. High-land *áus* is sown in the higher parts of Sylhet usually broadcast but occasionally transplanted. It is put down in March and April, harvested in August–September. Low-land *áus* is grown in the lower parts of the district, but is never transplanted. It is sown in January–February, cut in May–June. *Murali* is generally sown on lower land than in the case of *áus* of the high-land form, but on higher than the low-land. It is put down in February–March and cut in June–July. *Sáil* is always transplanted; sown in April–May, trans-
planted July–August, and reaped November to January. It is grown on land almost as high as *áus* land. *Áman*, like *áus*, is referred to two sections, according as grown on high or low ground. In the higher parts it is transplanted like *sáil*, but sown and gathered about a month earlier than that crop. In the lower parts of the district one variety is always sown broadcast, viz. the long-stemmed kind. *Kataria* is a form of *áman* sown in April–May, transplanted in May–June, and reaped in October–November. *Sáil bura* is grown on the very lowest land and is generally irrigated; sown in October–November, transplanted in December–January, and cut in April–May. The lands used are those portions of the *haors*, or large natural depressions in Sylhet, which are left dry by the receding of the water in the cold weather.

The Cachar rices enumerated are *dumai*, *murali*, *asra* and *sáil*. *Dumai* comprises the Cachar rices which correspond with the forms of *áus* sown broadcast on high-lands in April–May, never transplanted, and reaped in July–August. *Murali* is sown in March–April, sometimes transplanted about May and reaped in June–July. *Asra* is sown in March and April on low-lying lands, never transplanted, and reaped in December. *Sáil* is practically the same as the *sáil* of the Brahmaputra valley and the *sáil* of Sylhet. [*Cf. Sen, Final Rept. Settl., Jaintia Parganas, 1892–7, 8–9; Banerjei, Final Rept. Settl., Cachar Dist., 1894–9, 65, 111.*]

United Provinces.—The area in 1905–6 was 7,078,563 acres: 4,252,528 acres in Agra, and 2,826,035 acres in Oudh. In Agra the largest areas occur in Gorakhpur, 976,423 acres; Basti, 700,314 acres; Allahabad, 285,503 acres; and Azamgarh, 277,401 acres. In Oudh: Gonda, 565,895 acres; Bahraich, 236,399 acres; Sultanpur, 277,039 acres; and Barabanki, 262,225 acres; etc.

Methods of Cultivation.—Duthie and Fuller give a full and comprehensive account of the cultivation in these provinces; the races are very numerous, strongly marked, and may be assorted under three groups:—(1) those with a tall habit of growth, with the ear protruded from the sheath, feathery and drooping, and with thin usually yellow-husked grain; (2) those with a shorter habit of growth and stouter stems, with the ear not so prominent and carried more erect than that of the preceding, and with thick yellow or red-husked grain; (3) those with short, strong stem, ear partially enclosed in the sheath and grain-husk, dark-coloured or black. The first are most highly prized, the commonest being known as *naha*, *báns matti*, *báns phal* and *jhílma*. Of the second, *seondhi* and *sumhára* are the principal, while *sathi* is the most important of the third. *Munji* is a term of varying meaning, denoting in some places high-class rice, in others being merely a term for rice sown broadcast. Another classification is into transplanted from seed-beds or sown broadcast. As a rule, the finer

varieties, falling under the first two classes named above, are raised in seed-beds and planted out, while the coarser kinds are broadcasted.

Seasons. Rice is sown in all months from January to July, and harvested from May to November. The seasons in which the greater portion is grown are June to August for broadcast rice, and June to November for transplanted. Broadcasted rice is sown mostly on the break of the monsoon and is ready for cutting in August (*bhādoi*) or September (*kuāri*), and hence often known as *bhādoi* and *kuāri*. A certain quantity is also sown two months before the monsoon rain can be expected, and in this case there are two methods of cultivation. Either the rice germination is promoted and its growth stimulated by frequent and copious irrigation till the rains break, or, taking advantage of a fall of rain in April and May, the ground is ploughed up and sown, but the seed allowed to lie unirrigated, and the young plants should not come up before the advent of the rain induces germination. Nearly the whole of the transplanted rice (*jarhan*) is sown in seed-beds at the beginning of the rains, planted out after a fortnight or three weeks, and cut in *aghan* or November, hence also called *aghani*. A small portion, *boron*, *jethi* or hot-weather rice, is sown in January, planted out in February, and cut in May. This is only practised in slimy soils, along the edges of tanks or beds of rivers, which are planted with rice as the water becomes shallow from evaporation.

Sub-Himalaya. Much of the rice land in the Sub-Himalayan districts is prepared by being dug over by the mattock during the cold and hot weather months when the soil has been softened by a fall of rain. For land not dug in this way the number of ploughings varies according as the crop is to be sown broadcast or planted out, two or three in the first case, four or six in the second. For sowing, the soil must be thoroughly moist. If sown broadcast, 40 seers to the acre are held sufficient. If seedlings are to be raised in a nursery, the seed is sown more thickly. If the crop is to be transplanted, the nursery should be about one-twelfth the size of the field. The seedlings are taken up when about a foot high and planted in regular rows at distances of about 6 inches, 2 to 6 seedlings being planted together. For rice grown in the hot-weather months, frequent irrigation is necessary. Seed. Rice sown at the commencement of the rains and cut in August or September under ordinary circumstances needs no watering, but the transplanted varieties, which are not ripe till November, require two or three waterings when the rains cease. At least one weeding is given to broadcast rice. Planted rice in Cawnpore is said to be more frequently weeded than broadcast, but in Allahabad it requires no weeding at all. When ripe, the crop is cut with sickles in the same way as wheat or barley. [*Cf. Dist. Settl. Repts., U. Prov.; Nevill, Dist. Gaz. U. Prov.; Dist. Repts. quoted in Dictionary, v., 605-12.*]

C. Prov. *Central Provinces and erar.*—The area in 1905-6 amounted in the Areas. Central Provinces to 4,178,430 acres. The largest areas occur in Raipur, 1,264,198 acres; Bilaspur, 1,005,941 acres; Bhandara, 433,186 acres; Balaghat, 254,029 acres; and Chanda, 221,465 acres. Of the area under rice in 1904-5, it has been stated that 712,824 acres consisted of transplanted rice (302,794 irrigated and 410,030 unirrigated) and 4,193,045 acres of broadcasted rice (305,492 acres irrigated and 3,887,553 acres unirrigated). In Berar, the total area in 1905-6 amounted to 28,457 acres, almost entirely unirrigated.

RELATIONSHIP TO SOILS

O Y A
ATIVA
Cultivation

Crops in C. Prov., 1894, 10) states that the rice-growing areas fall into three tracts. The first lies in the north, and comprises the southern portion of the Damoh district, the Jabbalpur district and part of Mandla. Rice is here grown from seed, sown broadcast, and the crop is rarely irrigated. In black-soil fields it is generally grown as a catch crop before wheat. On lighter land it forms the only crop of the year. The second tract may be described as the Wainganga valley from its origin in the Seoni district to its termination in Chanda, and includes the southern portion of Seoni, the low country of Balaghat below the hills, and the eastern portion of Bhandara and Chanda, with isolated patches at the northern and southern extremities of the Nagpur district. In these localities most of the crop is grown from transplanted seedlings, and a large proportion is irrigated from tanks. The third tract consists of the plain of Chattisgarh and the Sambalpur district, forming the valleys of the Seonath and Mahanadi rivers. The common method of cultivation in Chattisgarh is to sow thickly broadcast and then to plough up the seedlings when they have made some progress, leaving the land a mass of mud, weeds and rice plants, from which a proportion of the latter make good growth. This process is known as *beasi* in Raipur and Bilaspur, and as *bilura* in Sambalpur. Transplantation of rice is almost unknown in Chattisgarh proper, *i.e.* in the Raipur and Bilaspur districts, and though tanks are numerous, the whole of the crop is practically unirrigated. [*Cf. Dist. Settl. Repts., C. Prov.; Rept. Operat. Dept. Agri., C. Prov.*, 1894-5, 15; Craddock, *Rept. Land Rev. Settl., Nagpur*, 1899, 61-2; *Rept. Dept. Land Rec. and Agri., C. Prov.*, 1902-3, 10-11.]

Rotation.

Irrigation.

Beasi.

Panjáb and North-West Frontier.—The area in the Panjáb in 1905-6 was 493,062 acres, and in the North-West Frontier 29,647 acres. The largest areas in the former were :—Kangra, 96,938 acres; Gurdáspur, 52,361 acres; Sialkot, 38,151 acres; Amritsar, 33,217 acres; Dera Ghazi Khan, 32,152 acres, etc.; in the latter :—Hazara, 12,793 acres; Peshawar, 12,053 acres.

Panjáb.
Areas.

Methods of Cultivation.—In the Upper Kangra valleys, where abundance of water, high temperature and a peculiar soil which favours its growth, are found in combination, rice is the staple product. It is also grown in the irrigated parts of Dehra and Nurpur. Coarser kinds are grown without irrigation in the more elevated parts of the district. There are upwards of 60 cultivated forms, of which the most esteemed are *begami*, *básmati*, *jhinwa*, *nakanda*, *kamádih*, and *rangari*. Each has its special locality, *e.g.* Rihlú is famous for its *begami*, Pálam for its *básmati*. Of the coarser kinds, the best known are *kathón* and *kolhena*; of the inferior unirrigated rices, *rora*, *kalúna*, *dhákar*. Where irrigation is possible, rice is not sown till June. In districts dependent on rain, the seed is sown as early as April. Harvest takes place in October.

Kangra.

Races.

Seasons.

There are three methods of cultivation. By the first, *bátar*, the seed is sown broadcast in its natural state and is the universal method on unirrigated land. In the second, *mach* or *lunga*, the seed is first steeped in water, forced under warm grass to germinate and then thrown into the soil, which has been previously flooded. By the third, *úr*, the young rice, about a month old, is planted out by hand at stated intervals in a well-flooded field. The growth of weeds in the rice-fields is rapid, and to check them the crop, weeds and all, are ploughed up. This practice is called *holdna*, and only the weeds suffer, as the rice springs up again more luxuriant than before.

Methods of
Cultivation.

Karnal.

In the Karnal districts, rices are divided into two well-defined classes—fine, known by the name of *ziri*, and coarse, of which the principal sorts are *munji* and *sánthi*. Of *ziri*, the principal varieties are *ramáli* and *rámjamáni*. *Sunkar* and *ansari* are coarser and grown chiefly where there is fear of too much water. Rice is grown only on stiff soil. The seed-beds are ploughed four or five times and carefully prepared, manure is spread on them, and the seed sown broadcast. More manure is then spread over the seeds and the whole watered. Four days after they are again watered, and after the fifth or sixth day they must be kept wet till ready to plant out. The rice-field is ploughed twice, and such manure given as can be spared. It is then flushed with 3 inches of water, and, if there are weeds, a plough is driven about under water. When the plough has worked the mud to a fine pulp, operators take the seedlings (*pod*) in handfuls (*júti*) and plant them one by one in the water. The field is weeded once at least and must at first be kept under water, but not more than about 6 inches deep. When the ears begin to form, the ground must be kept well wetted, but not too slushy. Reaping must be done directly the grain is ripe.

Manure.

Coarse rice is of two kinds, mentioned above, viz. *munji* and *sánthi*. The former is sown in spots liable to be flooded, since it cannot be drowned, the straw lengthening as the water deepens. The peculiarity of the latter (*sánthi*) is that it ripens within an extraordinarily short time from sowing. It requires but little water, if the soil is thoroughly moist, after the shoots are once up. Both kinds are sown in their final positions. After two or three ploughings, cattle are sent into the water to walk about and stir up the mud or a plough is worked under water. The seed is sown broadcast. No manure is used nor is the crop irrigated. [*Cf. Pb. Dist. Gaz.*; *Pb. Settl. Repts.*]

Kashmir.

Kash ir.—Lawrence (*Valley of Kashmir*, 1895, 326–36) gives a full and interesting account of rice cultivation. The varieties grown are very numerous but may be roughly divided into two classes, the white and the red, the latter being the more alpine form. As a food, the white is more esteemed, and the best are the *básmati* and the *kanyun*. Though of good quality, the white is less popular from the cultivator's point of view, since it is a more delicate plant and suffers more from changes of temperature and from the chill of snow-water. If the cultivator can obtain water and manure, he will continue to grow rice, and no rotation takes place. Where, however, water is uncertain, the rice land is allowed a fallow, and in some cases may be followed by cotton, maize, wheat, barley and *máh* (pulse).

White and Red.

Methods
Pursued.

There are two systems pursued: either the rice is sown broadcast, or first sown in a nursery and then planted out. Results show that the broadcast system gives the best outturn per acre. Preparatory cultivation commences in March, when the fields are hard and stiff. Where the soil is dry ploughed, cultivation is known as *tao*; where wet, as *kenalu*. Previous to ploughing, all the village litter and farm-yard manure are carried to the fields and ploughed in, or heaped in a place through which the irrigation duct passes, and so reach the fields as liquid manure. In June and July the labour of weeding the rice begins. The process is known by the name of *khushába*, and consists in weeding the crop, placing the rice plants in their proper places, and kneading and pressing the soft mud round the green seedlings. Only experts can

Bo bay and Sind.—In 1905-6 the total area was 1,512,261 acres ombay.
in Bombay; 1,013,902 acres in Sind. The largest areas in the Presidency Areas.
occur in the Konkan :—Thana, 304,872 acres; Kolába, 248,067 acres;
Kanara, 185,873 acres; and in the Karnátak, Dharwar, 143,606 acres;
Belgaum, 207,571 acres. Of Sind, the following may be mentioned :—
Lárkhána, 336,019 acres; Hyderabad, 215,297 acres; Karachi, 189,273
acres; Thar and Párkar, 134,192 acres.

The best soils are clays or clay loams with a substratum of other porous material. Embankments are formed, and the surface of the beds made level. Many fields on and under the Gháts are never manured, but the seed-beds invariably are, either by burning *ráb* material thereon or by direct application of manure. The rice-beds of Gujarat and those of the flat bottom-lands of the Konkan and elsewhere are regularly manured. In Gujarat tank-mud, 40 loads per acre, is a favourite application, and the practice of green manuring is also common. Castor cake may also be given as a top-dressing to supplement ordinary manure. Fish manure is similarly employed in the southern *tálukas* of Surat and parts of the Konkan. In Kanara and the forest tracts of Dharwar, leaves and twigs of certain forest trees are used as a green manure. Rice is sown broadcast, drilled, or broadcast in a seed-bed and thence transplanted. The first is seldom adopted except in the case of rice grown on marshy situations reclaimed from the sea. The second plan is very common in the western *tálukas* of Belgaum and Dharwar and above the Gháts in Kanara and in unembanked fields in Gujarat. The third method is most suitable in fields which are embanked and where the rainfall is over 80 inches, or

Irrigation.

Seed.

Yield.

where deficient rainfall can easily be supplemented by irrigation. Broadcasted or drilled rice requires a higher seed-rate than the transplanted, viz. about 120 lb. per acre; the seed-rate of the transplanted varies per acre from 25 or 30 lb. to 90 or 100 lb. In the Konkan, Mollison estimates a full yield under favourable circumstances at less than 4,000 lb. per acre. A full average from transplanted rice ranges from 2,800 to 3,200 lb. of grain per acre, while broadcasted or drilled yields on an average 1,800 lb. per acre. The cost of cultivation is estimated at Rs. 52-15a. per acre. [*Cf. Crop. Exper. Bomb. Pres.*; Mollison, *Textbook Ind. Agri.*, 1901, iii., 32-44.]

Madras.
Areas.

Madras.—The total area in 1905-6 was 7,561,611 acres, and distributed thus:—in Tanjore, 1,074,152 acres; Malabar, 831,545 acres; Kistna, 611,664 acres; South Arcot, 555,574 acres; South Kanara, 530,402 acres; Madura, 376,302 acres; Trichinopoly, 203,967 acres, etc. The *Final General Memorandum* for 1906-7 estimates the area for the year at 6,934,900 acres with a yield of 50,395,700 cwt., or 10·5 per cent. of the total rice area of British India.

Crops.

Seasons.

Methods of Cultivation.—In Malabar the crop is sometimes sown broadcast, but usually transplanted. There are several crops in the year, the principal of which are the *kanny*, sown in April-May and cut in August-September, and the *makaram* crop, sown in September-October, and reaped in January-February. These are the principal rice harvests, but there are intermediate crops in some places; and a third, known as *poonja*, sown in February and reaped in April-May. The greater portion of the land, however, bears only one crop.

South Kanara.

Seasons.

In South Kanara, rice is the staple crop. The land is classified, according to its capacity for irrigation, into *byle*, or rich wet land; *majal*, or middling wet land; and *bettu*, or land watered only by rainfall. On *byle* land of the best quality three rice crops can be raised in the year; on the best *majal*, two crops; while *bettu* land produces only one crop. The earliest rice crop of the season, on whatever land it may be grown, is termed *zenelu* or *carty*. The seed is usually sown in nurseries, highly manured, and the plants transplanted. In almost two months' time the crop comes to ear, and in about twenty-one days more is ready for reaping.

Tanjore.

Madura.

Seasons.

In Tanjore, rice is raised almost entirely by artificial irrigation. There are two chief kinds, viz. *kar* and *pishanam*, each including minor varieties. In all cases of irrigated cultivation, transplantation is the rule. A few coarser sorts, grown in some places beyond the delta of the Kauveri, and on rain-fed land, are sown broadcast. *Kar* is planted in June and reaped in October; *pishanam* in July-August and reaped in January-February. In the Madura district, rice is stated to be grown on almost every description of soil, the only essential being a constant supply of water. The seed may be sown broadcast, but the rule is to sow in nurseries. Sometimes the young plants raised in the nursery are transplanted to a second nursery, and afterwards carried to the field. As a rule, ploughing is done in June or July, after the early rains have softened the ground, and the seed is sown in nurseries at the end of July or beginning of August. After thirty days the seedlings are fit for transplanting, and in January may be harvested. When re-transplanting takes place, the young plants are suffered to remain in the second nursery about 35 days. Weeding is done about a month after sowing or transplanting. During the whole time the plants are in the ground they must stand in about 2 inches of water,

which must not be allowed to stagnate. In lands well supplied with water, as soon as the January crop is reaped, preparations are made for a second crop (*mási kódei*) raised in the same way as the first, but which comes to maturity about May. If the season be unpropitious during January–February, the second sowing will be in March, April or May and the reaping in July or August. The second crop is then called *adi-kódei*. Sometimes there may be three crops of rice raised in succession in a period of 13 or 14 months. [Cf. Sturrock, *Man. S. Canara*, 1894, i., 21, 199–204; Cox, *Man. N. Arcot*, 1895, i., 160–2; Francis, *Gaz. Anantapur*, 1905, 39; *A Root Parasite of Paddy in Malabar*, in *Agri. Journ. Ind.*, 1906, i., pt. ii., 169.]

Mysore and Coorg.—The only available figures are for 1903–4, when the area in Mysore was 792,754 acres, and Coorg, 79,763 acres. The largest areas in Mysore State occur in Shimoga, which grew 244,758 acres; Mysore, 117,749 acres; Hassan, 103,639 acres; Kadur, 97,905 acres, etc.

Methods of Cultivation.—In Mysore the *bara batta* or *punaji* seed is sown dry in the fields; the *mole batta*, germinated seed, in fields reduced to a puddle; and the *náti*, seedlings transplanted from a nursery after having attained a foot in height. Rice (*Mysore Gaz.*) fully describes these methods. There are two crops, the *hain* (rainy season) and the *karu* (hot weather). In the first, dry-seed cultivation is managed as follows:—from February to May, plough twice a month, having previous to the first ploughing softened the soil with water. After the fourth ploughing the field must be manured with dung, and after the fifth, watered by rain or from the canal. Three days later, the seed is sown broadcast and covered by the sixth ploughing. Any rain that falls the first 30 days after sowing must be allowed to run off, but should there have been no rain, the field must be kept inundated till the crop is ripe. If there have been occasional showers, inundation should not commence till the 45th day. Weeding and loosening the soil about the roots of the young plants and placing them at proper distances must be done three times, first on the 45th or 50th day; secondly, 20 days later; and thirdly, 15 days after the second weeding. These periods refer to crops that require 7 months to ripen. Rice which ripens in 5½ months must be inundated on the 20th day: and the weedings are on the 20th, 30th and 40th days. By the sprouted-seed method, ploughing takes place in June–July. During this time the field is inundated, ploughed four times, and at each ploughing turned over twice in two directions which cross each other at right angles. About the middle of July the field is manured, again ploughed, and the mud smoothed by foot. All water except 1 inch is let off, and the germinated seed sown broadcast. For 24 days the field must have some water every other day, and thereafter, till ripe, be constantly inundated.

In the method of transplanting rice, two distinctions are made, one called *bara-vági* or dry plants, the other *nirági* or wet plants. Low land is required for both. In *bara-vági* the ground is worked in the same way as for the dry-seed crop. In May it is manured and the seed sown thickly and ploughed in. If no rain falls till the 8th day it is watered, and again on the 22nd. From the 45th till the 60th day, the plants continue to be removed. The field must be inundated for five days before plucking up the seedlings for transplantation. The ground in which the dry seedlings are to be ripened is ploughed four times in the course of

THE RICE PLANT

Preparation.

eight weeks commencing about 15th May, and all the while inundated. The manure is given before the fourth ploughing. The mud is then smoothed and the seedlings transplanted into it, about 3 to 5 being stuck together in the mud at about a span distant from the next clump. The water is let off for a day, but afterwards the field is constantly inundated till the grain is ripe. In *nirági*, the ground is ploughed three times in February–March while it is dry. About the middle of May the field is inundated, and in the course of 15 days ploughed four times. After the fourth ploughing the mud is smoothed, the seed sown thickly and dung sprinkled over the surface, and the water let off. On the 3rd, 6th and 9th days water is again given, but must not stagnate. After the 12th day, inundation is commenced, and continued till the seedlings are fit for removal 30 days after sowing. The cultivation of the field into which the seedlings are transplanted is exactly the same as for dry seedlings. Various pulses are sown in the fields that are to ripen the transplanted crop, and are cut down immediately before ploughing for rice commences.

Hot
season.

Kár (or *karu*) crops (hot weather) are divided into three kinds according to the time of sowing. When the farm is properly stocked, the seed is sown at the most favourable season, and is called *kumba kár*; but if there be a want of hands or of cattle, part of the seed is sown earlier and part later than in the proper season. When sown too early it is called *tula kár*; when too late, *mésa kár*. The three methods of cultivation described above for the *hain* crop, viz. by dry seed, germinated seed, and transplantation, are found here also, except that in the case of *tula kár* no dry seed is ever sown.

Coorg.

In Coorg there is annually but one rice crop, except in a few valleys in the north. The rice cultivated throughout Coorg and in general use is the large-grained *dodda-batta*. A finer kind is the small rice *sanna-batta*, and a red variety the *késari*. For parched rice the *kalame* is the kind used. The seed is sown in a nursery, and in 20 or 30 days the seedlings are ready for transplanting, which takes place in July and August, regulated by the monsoon. The crop is cut in November or December. [*Cf. Rice, Mysore Gaz.*, 1897, i., 131–44, 217–8; ii., 317–8, 328, 563–4.]

Seasons.

Burma.

Areas.

Bur. a.—The area in 1905–6 was 9,283,801 acres. The districts of importance are, in Upper Burma :—Shewbo, 365,107 acres; Yamethin, 225,170 acres; Upper Chindwin, 160,783 acres; and Kathu, 159,596 acres. In Lower Burma :—Hanthawaddy, 1,114,359 acres; Thongwa, 843,840 acres; Pegu, 778,372 acres; Akyab, 599,880 acres; Thaton, 563,973 acres; Bassein, 536,720 acres; and Myaungmya, 518,508 acres. The crop is divided into three main classes : *kaukkyi* or late-rain paddy; *kaukyin* or early-rain paddy; and *mayin* or dry-weather paddy. *Kaukkyi* is said to occupy the largest area, viz. in 1904–5, 8,833,716 acres; *kaukyin* next with 332,117 acres; then *mayin* with 99,631 acres. The *Final General Memorandum* of the Commercial Intelligence Department estimates the area in 1906–7 at 6,988,500 acres. The yield was given as 96 per cent. of normal, and the surplus available for export was 2,374,000 tons cargo rice, equivalent to 40,237,000 cwt. cleaned rice.

Races.

Producti

Best Soils.

Methods.

Methods of Cultivation.—The most fertile land, where the largest amount and the best quality is grown, is found in the delta of the Irrawaddy. There are five methods of raising the crop, practised in different parts of the country :—(1) On the ordinary swamp land in low-lying plains where the rainfall is sufficient; (2) on level land from which the

rain-water runs off too quickly and irrigation has to be resorted to; (3) on land near the river-bank which is submerged and cannot be planted till after the highest rise; (4) in hill clearings; (5) a hot-weather crop obtained by irrigation either by means of dams or by water-wheels.

For the first three methods, ploughing commences in June, when the rains have softened the soil and rendered the use of the plough possible. Meantime nurseries have been prepared on higher ground and seed sown broadcast. By July or August the fields for the first two classes and the plants in the nursery are ready and the young plants are dibbled in, two together at intervals. In the case of riparian lands, the plants cannot be put out till about September; the harvest begins in November and is over by January. The hot-weather crop is planted in January-March, and is reaped about three months afterwards. The water necessary is usually obtained by throwing a dam across a stream, but at Meng-doon in the Thayet district a self-acting wheel is used.

In cultivating rice in hill-clearings, a site is first selected, thickly covered with bamboos and forest, which is all felled in April. After two months' drying, the fallen trees and scrub are set on fire, the ashes fertilising the ground. After the first fall of rain, the surface is slightly broken with a hoe, the ashes mixed with the soil, and the seed, usually rice and cotton or sesamum and cotton, sown broadcast. The rice and sesamum are reaped in September or October, and the cotton bolls picked in December to April. After this the hill-clearing is abandoned. [Cf. *Dist. Settl. Oper. Repts.*; *Upper Burma Gaz.*, 1900, ii., pt. 1, 337-41; Max and Bertha Ferrars, *Burma*, 1900, 48-56; Nisbet, *Burma under Brit. Rule and Before*, 1901, i., 330-43.]

MANUFACTURE.

Mills and Milling.—An important feature of the Indian rice trade is the rise and present position of the Burma power-mills. These mills had their origin in the very high cost of labour in that province and the disinclination of the Burman agriculturist to undertake any work he can avoid. In Bengal the rice crop is as a rule husked by the growers; in Burma it is conveyed to the market as paddy. It thus soon became evident that if rice was to become an important article of export, it must be husked at Rangoon. This gave rise to the important rice-milling industry of Burma. But these mills were for a long time greatly handicapped by the cost of coal imported from England. Moreover, the question of the disposal of the husk became a serious one. The discovery soon followed that the husk, previously wasted, might be utilised as the fuel to drive the mills. The husk is accordingly conveyed by special contrivances to the furnaces and there consumed, while a stream of water flowing below carries off the ash. By these and other inventions so great economies were effected that it soon became evident that not only was a great export trade possible, but that it would no longer pay to carry rice in husk to be milled at localities remote from the areas of production. To the skill and energy of the European inventors and owners of these mills, therefore, is due the credit of this great and prosperous industry.

According to the *Financial and Commercial Statistics*, there were 127 rice mills in India in 1904 employing 17,814 persons (mostly Madras coolies). The industry, however, is of importance only in Burma, which had of the above totals 114 mills and 17,016 employees. According to the statistical tables, the remainder were distributed as follows:—

Panjab 1 mill, with 33 employees; Bombay 1 mill, with 80 employees; Madras 11 mills, with 685 employees.

Uses of Rice.

Revenue Duty.—In the *Imperial Gazetteer* (iv., 257–8) it is stated that the “revenue derived from rice and millet beer amounted in 1902–3 to about 6 lakhs in Bengal and 11 lakhs in Burma; elsewhere it is inconsiderable. In Bengal, *pachwai* brewed from rice or millet is consumed by aboriginal tribes, and by the lower orders in general, in certain districts. It is valued both as a stimulant and as food. The bulk of the revenue which it yields is derived from licenses for manufacture and retail sale, which are put up to annual auction, the number and sites of the shops having been previously fixed. Licenses for the home-brewing of *pachwai* for domestic purposes are granted in certain districts to the headmen of villages inhabited by aboriginal races, on payment of a fixed fee for each household. In Burma the Native beer is brewed from rice. When consumed by certain hill tribes, mostly in Upper Burma, it is exempted from taxation, otherwise the excise system is similar to that in Bengal. It is almost as easy to brew this beer as to make a pot of tea, and as the main ingredient is a staple article of food, it is almost impossible to check private manufacture.” In the *Moral and Material Progress of India* the excise revenue from fermented local liquors, amounted in 1905–6 to £113,234 in Bengal and to £151,402 in Burma (see pp. 757, 760). The preparation of vinegar from rice is almost peculiar to Burma (see p. 1111). As regards Customs Revenue, rice and rice flour are the only articles on the export tariff schedule, the duty on which is levied at the rate of 3 annas per maund of 82½ lb. The revenue thus obtained during the years 1900–6 amounted to the following sums:—In 1900–1, Rs. 84,89,433; 1901–2, Rs. 90,87,957; 1902–3, Rs. 1,26,06,624; 1903–4, Rs. 1,20,31,363; 1904–5, Rs. 1,31,75,772; 1905–6, Rs. 1,15,11,257 (£767,417). The increase in recent years is doubtless to some extent the direct expression of the economies effected by the Burma milling industry.

It was said some time ago that India held a practical monopoly of the world's supply of rice and accordingly was justified in placing an export duty on the quantities sent to foreign countries. The duty above mentioned was first imposed in 1875, when oil, rice, indigo and lac were subjected to an export duty. In 1880 the duties on the other articles were remitted, and that on rice alone retained. But the exports of rice from the Southern States of America, from Madagascar, from Cochin-China, from Siam, from Japan, etc., have given a new conception of the trade. In fact, it might almost be said that but for the economies effected by Burmese milling, the exports would have by now been lost to India.

TRADE.

The foreign rice trade of India may be said to be very ancient. So long ago as 1503 Vertomannus (*Travels*, in *Hakl. Voy.*, 1811, iv., 577) made special mention of the exports from Mangalore. In present-day traffic almost the entire supplies of the cereal sent to foreign countries are drawn from Burma. It is employed as food, for distillation, and in the manufacture of starch. “Formerly the bulk of the rice exported from Burma consisted of ‘cargo’ rice, of which five-sixths was unhusked (or ‘paddy’) and only one-sixth husked. Gradually, with the extension of rice-mills, the proportion of cargo rice has diminished, this description being replaced by husked and cleaned rice, to the great advantage of the

THE HIGHEST PRICED EXPORT OF INDIA

**Y A
ATIVA
Trade**

trade. For the husk is used as fuel in the mills, the bran lying between the husk and the grain is exported at a good profit for pig-feeding, and a saving in freight is thus effected." "Rice is exported to every quarter of the globe, not more than about half of the total exports being consumed in Europe. Large quantities are sent to the Straits and Ceylon, to other parts of Asia, to East Africa, to the West Indies and South America. Indian rice penetrates to every region to which the Indian or Chinese coolie finds his way. It is to be noted that other countries, such as Siam, Cochin-China and Java, are already competing with India in these markets." Again, "The rice trade is conducted under conditions as regards the effects of the seasons which are unknown in other parts of India, for as yet no failure of the monsoon in Lower Burma has been recorded. The fluctuations of the export trade from Burma depend, however, upon conditions in other parts of India, since bad seasons cause the diversion to India of rice which would ordinarily be exported to foreign markets" (*Imp. Gaz.*, 1907, iii., 284-5). Burma has thus very properly been described as the granary of India, and it plays an important part in securing the balance of food supplies of the East generally.

Countries to
which
Consigned.

Granary of
India.

Staple of Burmese Commerce.—The importance of the rice crop may be seen by the fact that the EXPORTS often constitute the highest valued commodity and have often disputed the first position with raw cotton. Thus in 1904-5 the Rice exports (all kinds) were valued at Rs. 19,62,04,232; Wheat, Rs. 18,59,82,302; Cotton (raw), Rs. 17,43,46,872; Jute, Rs. 11,96,56,462; Opium, Rs. 10,62,34,442; Hides and Skins, Rs. 9,90,58,538; Tea, Rs. 8,46,54,867; Coffee, Rs. 1,66,09,757; and Indigo, Rs. 83,46,073. But in 1906-7 these positions were seriously changed: jute headed the list, followed by cotton, then rice, hides, tea, opium, wheat, coffee and indigo. Other raw products and partially manufactured products might be added to the above enumeration, but enough has been said to show the great importance of the rice traffic—the exports in that cereal being the staple of Burmese commerce.

Relative
Importance of
Rice.

Internal.—The total recorded internal trade transactions by rail and river amounted in 1906-7 to 35,038,390 cwt., of which 8,039,211 cwt. consisted of unhusked rice (paddy) and 26,999,179 cwt. of husked rice. The chief exporting centres were Bengal, 10,364,281 cwt.; Madras, 4,290,216 cwt.; E. Bengal and Assam, 1,228,575 cwt.; Sind, 2,905,816 cwt.; Bombay port, 949,010 cwt.; Calcutta, 6,755,856 cwt.; and Madras ports, 916,575 cwt. The chief imports were Calcutta, 9,470,405 cwt.; Bengal, 3,733,778 cwt.; Madras ports, 3,128,178 cwt.; Bombay, 1,754,606 cwt.; Madras, 1,195,222 cwt.; United Provinces, 460,072 cwt.; Karachi, 2,631,258 cwt.

**Internal
Trans-
actions.**

The total coastwise external traffic by sea in the same year amounted to 19,582,791 cwt. (5,085,681 cwt. unhusked and 14,497,110 cwt. husked). Of this Burma exported 16,259,498 cwt.; Bombay, 800,618 cwt.; Bengal, 309,708 cwt.; Madras, 463,487 cwt.; Sind, 1,684,085 cwt. The chief importing centres by coast were Bombay, 3,755,193 cwt.; Madras, 5,132,772 cwt., and Bengal 5,848,337 cwt.

Coasting Trade.

Foreign.—The EXPORTS of husked rice during the five years 1902-7 were as follows:—1902-3, 47,033,137 cwt., valued at Rs. 18,78,73,780; 1903-4, 44,441,186 cwt., valued at Rs. 18,95,42,429; 1904-5, 48,873,297 cwt., valued at Rs. 19,47,22,505; 1905-6, 42,211,869 cwt., valued at Rs. 18,41,06,407; and 1906-7, 38,054,054 cwt., valued at Rs. 18,32,55,332.

**Foreign.
Husked.**

Unhusked.

In addition to this, a considerable quantity of unhusked rice (rice in husk) or paddy, amounting in 1906-7 to 655,132 cwt., valued at Rs. 19,98,886, and smaller quantities of rice-flour, viz. in 1906-7, 6,165 cwt., valued at Rs. 44,484, are annually exported. Robertson (*Rev. Trade Ind.*, 1904-5, 23-4) states that both in regard to quantity and value the trade of 1904-5 was the largest known, and that the average price was 7 per cent. lower than in 1903-4. The bulk of the exports of husked rice is always from Burma, which, out of the totals above mentioned, contributed as follows:—1902-3, 36,791,543 cwt.; 1903-4, 33,346,351; 1904-5, 37,514,518; 1905-6, 31,067,895; and 1906-7, 28,105,443 cwt. Bengal comes second with, in 1905-6, 8,955,237, and in 1906-7, 4,736,786 cwt. Madras in 1905-6 supplied 1,500,945, and in 1906-7, 3,333,774 cwt. Sind in 1905-6 gave 303,354 and in 1906-7, 1,344,529 cwt. Lastly, Bombay in 1905-6 furnished 584,440 and in 1906-7, 533,443 cwt. According to Robertson, unhusked rice goes entirely to Ceylon, except as a constituent of husked rice to prevent its heating. Of cleaned rice the principal destinations west of Suez are Germany, which, in 1905-6, took 4,968,851 cwt., valued at Rs. 1,97,42,006; United Kingdom, 3,473,883 cwt., valued at Rs. 1,48,95,095; Holland, 2,513,425 cwt., valued at Rs. 89,00,902; Austria-Hungary, 2,442,632 cwt., valued at Rs. 87,55,678. Of the Eastern section of the trade, the most remarkable feature is the development in the export to Japan, which amounted in 1904-5 to 9,277,239 cwt., valued at Rs. 3,52,13,937, an increase of 32 per cent. over the quantity for 1903-4, though it fell in 1905-6 to 6,593,531 cwt. After Japan in 1905-6 comes Ceylon with 5,976,582 cwt., valued at Rs. 3,21,23,634; then the Straits Settlements with 5,028,694 cwt., valued at Rs. 2,05,89,495.

Countries to
which Exported.

Europe.

Japan.

Ceylon.
Straits
Settlements.

The IMPORTS into British India do not amount to much, viz. in 1905-6, 965 cwt. unhusked rice, valued at Rs. 3,263, and 7,230 cwt. husked rice, valued at Rs. 40,018, the bulk of which comes from the Straits Settlements.

Trans-
frontier.

Of the trade by land (Trans-frontier) the latest available figures are for 1906-7. In that year the quantity of husked rice EXPORTED amounted to 69,050 cwt., valued at Rs. 4,31,739, and unhusked rice to 29,682 cwt., valued at Rs. 1,64,542. The Trans-frontier import trade is considerable. In the year under review, IMPORTS of husked rice amounted to 1,173,025 cwt., valued at Rs. 76,08,888, and of unhusked rice to 1,349,532 cwt., valued at Rs. 49,84,420. Almost the whole of this, husked and un-husked, comes from Nepal, viz., in 1906-7, the former, 945,640 cwt., and the latter, 1,215,852 cwt.

Ind., 8; Lisboa, *l.c.* 11. The *shamula*, *shama*, *sâme*, *sanwa*, *jhungara*, *mandira*, *banti*, *chamalu*, etc. A tufted annual, extensively cultivated as a rainy-season crop over the greater part of India and on the Himalaya up to 6,500 feet. In *The Bower Manuscript* (Hoernle, transl., 151) mention is made of "gruel made of *syâmakâ*," and this has been regarded as denoting the present millet. The MS. in question was found at Kucha near Khotan, and is of the 8th century.

Poor-man's
Millet.

This is the quickest-growing of all the millets, and in some localities can be harvested within six weeks of being sown. It thrives best on light sandy soil. Banerji (*Agri. Cuttack*, 1893, 76) says it often follows *kangu* (*Setaria italica*). The soil is ploughed twice, and the seed sown broadcast in the middle of May to the middle of June. In about a month and a half the land is thoroughly weeded. Rain is required till about the middle of August, when the crop is cut. Of the United Provinces, Duthie and Fuller state that it is sown at the commencement of the rainy season and a spring crop usually follows it. The seed is sown at the rate of 10 lb. to the acre, and the young plants require at least two weedings. In the drier regions of the Doab it is frequently grown as a subordinate crop with *juâr* (*Sorghum vulgare*). The yield varies from 8 to 10 maunds grain to the acre. In Bombay the area devoted to it in 1905-6 was 43,586 acres. Mollison (*Textbook Ind. Agri.*, 1901, iii., 61) states that the land is prepared as for *bâjra* (*Pennisetum typhoideum*). The seed is drilled with a four-coultured plough in June-July at the rate of 6 to 8 lb. to the acre. The rows are about 12 inches apart, and the plants should be thinned out where the seed is sown too thickly. The crop is weeded and intercultured with the bullock-hoe as with *bâjra*. It ripens in September-October. In the Deccan it is usually grown on poor, light upland soil where the rainfall is moderately heavy, and on such land a yield of 400 to 500 lb. grain and 1,500 lb. straw is a full average crop.

Six Weeks' Crop.

Seasons.

Yield.

The grain is consumed chiefly by the poorer classes, with whom it has the special merit of ripening early. It is eaten boiled in milk or is parched. Leather (*Agri. Ledg.*, 1901, No. 10, 368; 1903, No. 7, 150, 178) gives the following analysis:—moisture, 7.72; oil, 4.39; albuminoids, 7.06; soluble carbohydrates, 67.56; woody fibre, 7.44; soluble mineral matter, 1.70; sand and silica, 4.13; total nitrogen, 1.18; albuminoid nitrogen, 1.13. In the Madras Presidency and in Mysore the straw is much used as a cattle fodder, and in the Meerut district it is sometimes grown as a fodder crop. [*Cf. The Bower Manuscript* (Hoernle, transl.), 1893-7, 137; Church, *l.c.* 49; Basu, *Agri. Lohardaga*, 1890, pt. ii., 29; Rice, *Mysore Gaz.*, 1897, i., 114-6; Mukerji, *Handbook Ind. Agri.*, 1901, 259.]

P. axi u, Jacq.; Prain, *Beng. Plants*, ii., 1179; *P. jumentorum*, Pers.; Duthie, *l.c.* 9; Lisboa, *l.c.* 18-22. Guinea Grass, *gini gawat*, *geneo-pullu*, *gini hullu*, *nauka-thau-hau*, etc. A tall perennial native of Africa, and now cultivated in India.

Guinea
Grass.

Is best propagated by root cuttings. A sandy soil is most suitable. After the ground has been prepared in the ordinary way, the roots should be planted out 2 feet apart on the flat, at the commencement of the rains, care being taken to arrange them so as to form lines at right angles in both directions. If planted at any other time, the field should be inundated with water immediately after planting. When the crop is established the rows should be ridged up in the direction of the slope. Subsequently, according to Mollison, Guinea Grass can hardly get too much water or manure, but the water must not be allowed to stagnate. The best manure is well-rotted farm-yard, and it should be applied in dressings of at least 5 tons per acre every fourth time the crop is cut. Crops are cut about eight times in the year, and plantations should be renewed every three years. Of the Poona and Surat Farms, Mollison says that it has been known to give outturns of 20,000 to 35,000 lb. per acre according to season. [*Cf. Dept. Land Rec. and Agri. U. Prov. Bull.*, 1897, No. 6; Mollison, *l.c.* 233-6; Leather, *Agri. Ledg.*, 1901, No. 10, 368; 1903, No. 7, 156, 170.]

Ancient Grain.	country up to 10,000 feet on the Himalaya, but nowhere to any great extent. Stein (<i>Ancient Khotan</i> , 376) says he found at the Niya site (3rd century) some ancient straw among which the husk of this species had been recognised by the authorities of Kew.
engal.	Bengal. —Roy (<i>Crops of Beng.</i> , 1906, 58-60) states that this millet does best on a heavy loam and luxuriates on newly formed <i>char</i> lands. The land is ploughed after the 15th December, up to January or even to 15th February, and harrowed two to four times after each ploughing.
Seasons.	By the time of the fifth or sixth ploughing the clods are broken with the hammer and the seed sown broadcast about the 15th February, at the rate of 5 seers to the acre, then ploughed in; but to cover the seed, the land is again harrowed. When the plants are 6 inches high, the field is weeded if necessary. The crop is harvested about the 15th March to the 15th May. The average yield is about 24 maunds per acre, valued at Rs. 48.
Yield.	U. Prov. United Provinces. —It is grown as a hot-weather crop, irrigated from wells. Sown in March at the rate of 10 lb. to the acre, and ripens towards the end of May. Yield, six to eight maunds of grain per acre. In Bandelkhand there are two varieties, <i>phikai</i> and <i>rahi</i> . The former is sown a little earlier than the latter, and yields a heavier outturn.
Two V 'eties.	o bay. o bay. —The area under this crop and under <i>P. miliare</i> are returned together. They are generally distinguished by the names of <i>vari</i> and <i>sáva</i> respectively. In 1905-6 they occupied 231,948 acres in Bombay and 2,140 acres in Sind, and are said to take the sixth place among the cereals of Bombay. Their cultivation is almost limited to the Konkan and the Ghát parts of Násik, Poona, Sátára, Belgaum and Dhár-wár. In these districts <i>P. miliaceum</i> is a <i>kharif</i> crop, depending on natural rainfall, and is never irrigated. According to Mollison, it is raised like <i>nágli</i> (<i>Eleusine coracana</i>) from <i>râbed</i> seedlings transplanted.
Area.	When the seedlings are growing, the field is ploughed three or four times during the first three weeks of the rains. About 1 lb. of seed per <i>guntha</i> (one-fortieth acre) is sown broadcast on the seed-bed. It is grown without manure, and is commonly hand-weeded once in August. If transplanted early in July, the late varieties of the crop ripen towards the end of October.
Seasons.	A full average crop on good <i>varkas</i> land (<i>i.e.</i> upland soils of the Konkan) will yield 700 to 750 lb. grain per acre, worth 40 to 45 lb. per rupee. In Gujarat the crop grown is known as <i>cheno</i> , and according to Mollison is agriculturally very different from the crop of the Konkan and Ghát districts.
Yield.	It is grown in garden lands as a hot-weather irrigated crop. When ginger or other garden crop is removed in December-January, the land is ploughed several times and beds formed for irrigation. The seed is sown broadcast, 10 lb. per acre, and lightly covered. Light irrigation is given as required, and the crop is hand-weeded once. If sown at the end of January it comes into flower in March and is fully ripe in April.
Gujarat Form.	A good crop yields about 2 tons straw and 1,000 to 1,200 lb. grain per acre.
Seasons.	Uses. —The GRAIN is considered digestible and nutritious, and in many places is eaten whole, being cooked like rice. In Bihar, when boiled and parched, it is called <i>marha</i> , <i>manhra</i> or <i>már</i> . Prepared with milk and sugar it is a favourite food at marriage ceremonies. Near Simla it is sometimes used as bread in the form of <i>chapatties</i> , called <i>chinatti</i> (pan-cakes). Leather gives the following average analysis of three samples

Little
illet.

Of Bengal, Roy (*Crops of Bengal*, 62) states that this millet is largely cultivated in the Lower Province. No manure is used, and it may be followed in rotation by a *rabi* crop. The land is ploughed and harrowed from January to March and the seed sown from March to May, at the rate of 18 seers per acre. No further operations are necessary till August or September, when the crop is cut and threshed like *áus* paddy. The yield is stated to be 24 maunds per acre. In the United Provinces its cultivation is confined chiefly to the southern hilly districts. It is sown in June and reaped in October, forming, together with *kodon* (*Paspalum scrobiculatum*), the crop generally taken from the poorest land in the village. In Bombay, the description from Mollison given under *P. miliaceum* applies equally to the present crop.

PAPAV AN PIU ; PAPAVERACEÆ. Opium is an inspissated juice obtained by scratching the unripe capsules of *Papaver somniferum*, Linn., and allowing the milky sap, which exudes therefrom, to dry spontaneously. There may be said to be two chief kinds of opium, that used for medicine (produced chiefly in Asia Minor), and that smoked, eaten, etc. (grown in India and China).

D. P.,
vi., pt. i.,
15-105.
Opium.

istory.—Various species of poppy are mentioned by the early Greek writers (Homer, etc.) as ornamental garden plants or as attractive-looking weeds of the fields ; the merits of the seed as an article of food and as affording oil were extolled before the discovery had been made of the somniferous property of the capsules, and certainly long anterior to the recognition of the value of the milky sap. The capsules, stems and leaves were employed by the Greeks in the preparation of an extract called *meconium* (cf. Hippocrates, Theophrastus, etc.), which was employed as a porific drug and used in the fabrication of a soothing beverage exactly corresponding to the *post* of the Panjáb to-day and the *kuknár* of Akbar's time. Lastly came the discovery of the more potent nature of the inspissated sap, the *opion* of the Greeks, a word that may be spoken of as the diminutive of *ópis*—the juice. *Papaver somniferum* was grown in Asia Minor for its capsules, which the Arabs carried all over the East, even to China, sometime before the Greek discovery of the value of the juice.

Oil-seed.
Capsules.
Milk.

Meconium.

Post and
Kuknár.

The discovery of opium began to attract attention about the 3rd century B.C. Theophrastus was acquainted with it, and describes the method of obtaining it by scratching the green pods. Virgil (*Georg.*, iv., 545) speaks of the lethean virtue of the plant. Pliny pays special attention to the medicinal value of

Greek
Knowledge.

Roman
Empire.

opion, while Dioscorides narrates with the minutest detail the process of extracting and manufacturing the drug, and is careful to distinguish it from the older preparation *meconium*. In his time the drug would seem to have come mainly from Asia Minor. Indeed, during the Roman Empire, as also the early Middle Ages, the only sort of opium known was that of Asia Minor. And even in the 13th century Simon Januensis (physician to Pope Nicholas IV.) spoke of *Opium thebaicum*.

Arab
Influence.

But if the Greeks discovered the potent juice—opium—the Arabs were chiefly concerned in disseminating the knowledge of the plant and its uses. The Arab medical writers from about the 9th to 12th centuries give a full account of it derived almost exclusively from Dioscorides and Galen. That the followers of the faith of Islam proclaimed the properties of opium to the people of India and China there can be no doubt, since the Sanskrit and all the vernacular names in use to-day are clearly traceable to the Semitic corruption of *opos* or *opion* into *afyun*. Thus the Hindi *afim* points to *afyun* as the transitional stage from *opion*. In the same way the Arabs carried the poppy capsules and opium to China, hence the name *ya-pien*, also *a-fou-yong*, in the Chinese language. Previous to the Táng dynasty the opium poppy was apparently not known to the Chinese.

Afyon.

Sanskrit Name.

According to one writer the Sanskrit name is *ahipena*, and, explained as meaning "snake venom," would thus not be derived from the Greek. But it is more often written *ahipana*, a word which most authors speak of as being quite modern and derived directly from the Arabic. Sir George Birdwood (*E.I.C. First Letter Book*, liv.), for example, says, "It does not occur anywhere until it appears in a Sanskrit dictionary published in Calcutta about seventy years ago." Mr. R. M. Dane (*Hist. Mem.*, in *Rept. Roy. Comm. on Opium*, vii., app., 28-63) says that evidence was placed before the Commission to the effect that it is mentioned in the *Bhavaprakasha* and other Ayur-Vedic medical works supposed to have been written not less than 800 years ago. He then adds that the history of the production and use of opium in India before the commencement of the 16th century is, however, obscure.

Indian
Knowledge.

On the other hand, Grierson (*Bihar Peasant Life*) gives a complete vocabulary of words for the plant, its varieties, every part of it, as also every product it affords and every feature and stage in its cultivation and manufacture. Still there can be no possible doubt that the poppy cultivation of Bihar does not date further back than a couple of centuries or so. While that view is doubtless correct, and extreme caution is necessary, still there are words, such as *post* or *pust* (already mentioned), that seem quite unconnected with Greek literature, and which indicate, as has been suggested, a more ancient knowledge of the plant than in its special sap—opium. The word *post* usually denotes the capsules, and in South India it becomes *postaka-tol*. Dutt tells us that in Sanskrit the poppy capsules are *khákhas* and the seeds *khashila*, but that there is no classical name for opium. The seeds are *kashkash* in India generally, and in South India *gashagasha*. So also in China there are names for the poppy that carry the knowledge of the plant back to the 7th century. Dr. Edkins (*Hist. Notes on the Poppy in China*, in *Rept. Roy. Comm. on Opium*, 1894, i., app., 146-58) points out that in the 10th century the Emperor Sung T'ai-tsu directed the first great medical work to be written; in that, the names given to the poppy are *minang* (= millet vessel) and *ying-su* (= jar-millet). Both names of necessity denote the poppy capsule and its seeds, and involve most probably a knowledge in their respective properties prior to the discovery of opium. Su Sung compiled the second great medical work (which appeared in 1057 A.D.), and it is there stated that "the poppy is found everywhere. Many persons cultivate it as an ornamental flower. There are two kinds, one with red flowers and another with white." This, therefore, implied that though the name that nowadays denotes opium had not come into use, the two forms of the opium-yielding plant were well known in China at the period mentioned. Lin Hung, in the 12th century, alludes to the milk from poppy heads. A poem written during the Sung dynasty speaks of the poppy fields resembling snow. Thus there can be no doubt the opium poppy was extensively cultivated in China long anterior to the importation of India opium. Wang Shih, in the 13th century, speaks of the prepared drug as simply magical in the treatment of dysentery.

Early
Exports
from India.

At the beginning of the 16th century the opium imports into China from India had not only been fully established, but the cultivation of the poppy plant and the manufacture of opium at Malwa had become regular industries, thus

fully two centuries prior to the conquest of Bengal by Clive. And there can be no manner of doubt that prior to the British, the Portuguese controlled the Chinese opium exports from India. It is significant that while Baber (*Memoirs*, 1519, 334) makes no mention of opium in connection with his discussion of the revenue of Bihar, his grandson, the great Emperor Akbar, on the subjection of Malwa and Cambay, found the opium traffic a distinctive and important feature of these new dominions. Moreover, Abul Fazl specially mentions Fatehpur, Allahabad, Ghazipur, Lahore, etc., as concerned in poppy culture, and lays stress on the excellence of the crop in Malwa. Sir J. B. Lyall (*Hist. Sketch in Rept. Roy. Comm. on Opium*, vii., app., 5-28) says that it seems certain the Mughal monopoly began a little later than Akbar's time. He, moreover, came to the conclusion that it probably was confined to Bihar. The right to manufacture and sell the drug was finally placed by the Muhammadans under direct supervision; it was farmed out, and land devoted to this cultivation subjected to a higher tax than that for other produce. But as bearing on the probable date of the State monopoly, it may be mentioned that in the *Mirat-i-Ahmadi* we learn of the systems of taxing and the revenue realised from opium by the city of Ahmadabad in the time of Sultan Muzoffar and other Gujarat kings, before the overthrow of the dynasty by Akbar in 1573 A.D.

Mughal
Monopoly.
Bihar State's
Monopoly.

The antiquity of the opium traffic may be judged of by the fact that Giovanni da Empoli (in 1511) mentions that Alboquerque had captured eight "Guzzarate" ships that contained, among other merchandise, "*arfuin*, for so they call *opio tebaico*." In 1516 Barbosa tells us that this drug was among the articles brought to Malacca by the Arab and Gentile merchants to exchange for the cargoes of the Chinese junks. He also informs us that opium was carried from Arabia to Calicut, and from Cambay to Calicut, the Arabian being one-third higher priced than that of Cambay. Garcia de Orta, in 1563, published a full account of the Indian habit of eating opium, and Frederike speaks of going (1568) to Cambay, where he purchased sixty parcels of opium. Shortly after, Acosta (*Tract. de las Drogas*, etc., 1578, 408) and Linschoten (1598) amplified very greatly the particulars made known by Garcia regarding the Indian habit of eating opium. Bocarro (1644) laid stress on the importance of the three great products of Cambay, viz. opium, indigo and cotton. Thevenot (*Travels in Levant, Indostan*, etc., 1687, pt. ii., 97) mentions the use of opium in Persia. In the *Tuzuk*, reference is made to the Governor of Bihar being much given to *kuknar* (opium-hemp), and his consequent neglect of his duties. If this can be accepted as denoting a Bihar cultivation, it would be the earliest known. The first direct mention of Patna opium appears to be given by Ralph Fitch, an Englishman who travelled in the East from 1583-91 A.D., and who visited Agra, Benares, Patna (Patenaw). He describes the last town very correctly "as a very long and great towne," which had a large trade in cotton, sugar and opium. The Abbé Raynal (*Hist. Philosoph. des deux Indes*, 1770, a work translated into English in 1777, i., 424) says that "Patna is the most celebrated place in the world for the cultivation of opium. Besides what is carried into the inland parts there are annually 3,000 to 4,000 chests exported, each weighing 300 lb." Alexander Hamilton, (*New Acc. E. Ind.*, 1727, i., 315; ii., 22) speaks of the chiefs of Calicut vending from 500 to 1,000 chests of Bengal opium yearly, up in the inland countries where it is very much used. Mr. J. F. Finlay (*Rept. Roy. Comm. on Opium*, ii., 371-99) furnishes particulars of the proposals to abolish the Government monopoly. He gives the early history and fixes the present arrangements as dating from 1797.

Establishment of
Present System.

Thus then the opium monopoly was a direct legacy from the Muhammadan rulers of India and from the early Portuguese traders, that had to be assumed by the British shortly after the battle of Plassey (1757). Mention, for example, is repeatedly made of the traffic having expanded so inordinately as to have forced the East India Company to assume its control and supervision in 1781. But prior even to the advent of the Portuguese, the Chinese had become possessed of a full knowledge of the drug. Wang Hsi (who died in 1488 A.D.) speaks of opium being obtained from Arabia and being the produce of a poppy with red flowers. He died thus ten years before the arrival in India of Vasco da Gama, and not only describes the use of opium, but the methods pursued in the cultivation of the poppy and the extraction of the narcotic. There can, therefore, be no sort of doubt that the cultivation of the poppy plant, as a source of opium, was fully established in China by the middle of the 15th century. The prohibition against foreigners trading with China, issued in 1523, was a

Establishment of
Chinese
Production.

History

consequence of Japanese raids, but its immediate effect was to lessen the supply of foreign opium, and in consequence regulations were issued with the view to improve and extend Chinese home production.

Opium
Smoking.

Dr. Edkins, from whom most of the above historic facts regarding China have been derived, says that towards the end of the Ming dynasty the legitimate practice of taking opium medicinally was destined soon to change into that of smoking it. The new phase, he affirms, was intimately associated with the introduction of tobacco-smoking from the Philippine Islands. Tobacco reached China about 1620 A.D., or just about the time that King James I. published in England his *Counterblast to Tobacco*, and the last of the Ming Emperors prohibited the smoking of tobacco. But the habit nevertheless spread rapidly, and unfortunately various substances came to be mixed with the tobacco, such as opium, arsenic and the like. These were for some years used as flavouring ingredients, but in time they became the chief materials smoked. It may thus truly be said that tobacco was a lesser evil than the early Chinese reformers supposed, while opium-smoking proved a far greater danger than they feared. The Emperor Ch'eng Tsung is much to be respected for his strong moral convictions. He made great efforts to cope with the evil of narcotic indulgence, but in vain. According to Bretschneider, opium-smoking is a Chinese invention and quite modern. Nothing, he adds, proves that the Chinese smoked opium before the middle of the 18th century. Dr. Edkins regards the connivance of the Chinese authorities (during 1729-96), from the highest to the lowest, as having served to render repressive measures futile, both against local production and foreign importation. Opium-smoking originated, moreover, in a lawless locality, at a great distance from Peking, and (as observed by Holmes) "while the Court at Peking was endeavouring to suppress the foreign trade in opium, from 1796 to 1840, it did not or could not put a stop to the home cultivation of the drug, since a Chinese Censor in 1830 represented to the throne, that the poppy was grown over one-half of the province of Chekeang, and in 1836 another (Cho Tsun) stated that the annual production of opium in Yunnan could not be less than several thousand piculs" (*Encycl. Brit.*).

Method of Sale.

This state of affairs culminated, and naturally so, in a conflict of interests as represented by local production on the one hand (an item of provincial revenue) and foreign importation on the other (an item of Imperial revenue). While the British and Indian Governments were in treaty with the Emperor of China, with regard to the enforcement of such restrictions on the foreign traffic as the Imperial Government of China deemed desirable, the provincial authorities of China, as represented by the Commissioner Lin Tse-hsu, demonstrated their desire for the complete discontinuance of the foreign supply by destroying £2,000,000 worth of opium, the property of British traders. Had the Chinese Government taken the course open to it, and that, too, without arbitrary injury to a trade of large proportions (the growth of several centuries), namely to impose a gradually increasing taxation on imported opium; had it exercised also the power, which it should have possessed if it did not do so, of restricting or prohibiting the cultivation of the poppy within its own territory, little would have been heard of the perplexing Opium Question of the present day.

By the middle of the 18th century Bihar had become the province in which opium of the best quality and greatest quantity was produced. In the anarchy of the period, the Government monopoly had fallen into abeyance. The system under which, in the early part of the century, business in opium was conducted, in that part of India, is described by Ram Chand Pandit. In the first year of the British monopoly he was one of the joint contractors of the opium provision. There was, he tells us, a body of Native merchants, then resident at Patna, known as the opium-dealers, who made advances to the cultivators and received in return the opium produced, took it to their houses, and made it up in the form required by the exporters. After the growers had delivered as much as liquidated the advances received, they disposed of the surplus as they thought fit, and the price rose accordingly. In October, the opium being prepared in the required form, the merchants used first to offer it for sale to the Dutch, having previously agreed among themselves as to the rate they would accept. A dealer owning, say, 500 maunds would dispose of 200 to the Dutch. After such preliminary sales, the dealers would then go to the English merchants and offer a further quantity, at a higher rate, and finally they would go to the French and dispose of some more at a still higher rate. Thereafter, say in November, the Dutch would make a second contract with the opium merchants, but at a higher price

than their first agreement, and usually by this time the *pykars* or small traders, who had picked up here and there odd parcels, brought their much adulterated article to market and thus lowered the price of the closing sales. The usual price averaged from 100 to 150 rupees per maund, but might rise to Rs. 200 or, during the wars among the Europeans, would fall to ruinous rates—Rs. 70 to Rs 75.

With such a state of affairs it can be no matter for surprise that corruption became universal with the growers, the traders, and the exporters, nor that misunderstandings should have threatened both internal and external peace and thus rendered imperative some system of supervision. An end, as it was thought, was put to all disputes in 1773 by the Governor of Bengal, Warren Hastings, assuming supreme control, on behalf of the East India Company, an agreement having been entered into to supply the Danes, Dutch and French with fixed amounts annually. From 1773 to 1797, in virtue of this new arrangement, the right to the exclusive manufacture of opium, on account of the Company, was sold annually in the first instance, but from 1781, by four-year contracts, on private bargain. In 1785 the contracts were opened to public competition and assigned to the highest bidder. Definite stipulations were thenceforward exacted from the contractors with a view to protecting the cultivators from being compelled to grow the poppy; for securing to them freedom from vexatious imposts and ensuring a fair price for their produce. The cultivators, on the other hand, were made liable to penalties for keeping back the opium produced, and to a deduction of *batta* (assessed by arbitrators) upon opium adulterated. Dealing in opium contrary to the conditions of the monopoly was made criminal by whomever conducted. But in spite of all the regulations that could be framed, the system of farming became oppressive. Cultivators were often compelled by the contractors to grow the poppy when they had no desire to do so. The contention was advanced that the contractors must have an assured production, and hence, they said, once land came under opium, it had throughout the period of contract to continue to produce it. If the owner or cultivator of opium land objected, he should, they said, be compelled to vacate it and allow some one willing to grow poppy to be placed in charge. Instances of such high-handedness and abuse became so rife and flagrant that the Board of Directors were forced to seek some other plan of operation than that of farming out the right to produce a drug of such potency.

It had been early resolved by the Company that the profits of opium traffic should be credited to Revenue, not to Commerce. The country, and not the shareholders, thus participated in the profits. The vested interests of the Indian people were thus early recognised as demanding efficient control. Ram Chand Pandit, who could contrast the free-trade system, in which he had, in fact, participated, with the subsequent contract system and its grievances, bribery, corruption and dishonest weights, etc., admitted that the carrying on of the opium traffic as a State monopoly was the best mode "as well for the *raiyyat* as for the preservation of the quality and the good of the country at large." After discussing the many recommendations of the new system, viz. constant market, liberal advances, freedom from all compulsion, etc., he added that the *raiyyats* should be punished whenever detected either delivering adulterated juice or disposing of the produce other than to the Company, and that after receipt into warehouse it should be made up with the greatest care so that its good quality might redound to the honour of the agent. It will thus be seen that in the growth of the present Indian opium traffic, free trade was tried and found wanting: that the contract system proved defective and pernicious; hence that direct control was hailed by the people of India as a greatly needed and much valued reform.

The Government of India, in a Dispatch issued during the Marquis of Ripon's administration, stated their case fully. One passage from that dispatch gives the key-note to the whole controversy—"The economic objections to the manner in which opium revenue is raised, whether in Bengal or Bombay, may be admitted to be considerable. In the former case, the Government itself engages in private trade, a course which is open to obvious objections. In the second, a very heavy export duty is imposed. In both cases the course adopted interferes with and restricts the free production of the trade in opium. It cannot be doubted that it would be highly profitable to any private trader to pay for crude opium a very much higher sum than is paid now by the Government to the cultivators of Bengal. If, therefore, supposing such a thing to be possible, no restriction were placed upon the cultivation of the poppy, and if, at the

same time, the export duty were taken off, it is certain that an immense stimulus would be given to the production of opium, and that China would be flooded with the Indian drug. Thus, in direct proportion to the removal of the economic objections, the moral objections would be intensified in degree." "If, therefore, the policy is to be not merely theoretical, but is to be productive of some practical good, it must aim, not only at the disconnection of the Indian Government with the opium trade, but at the total suppression of the trade itself."

Chinese
Production.

China produces locally the major portion (some writers say nine-tenths) of the opium it consumes. The province of Yunnan, where opium indulgence is carried to the greatest extent, is self-supporting in the matter of opium, that is to say, it exports opium but imports none. But Yunnan does not stand alone. Mr. A. Hosie, Consul-General, says that with the province of Ssu'ch'uan (*Report*, 1904) the greater profit of opium as a crop has driven wheat very largely from the list of surplus products exported from the province. Out of a population of 45 millions, nearly 3 millions are opium smokers. The locally produced article is gradually displacing the imported, and the province even now exports to other parts of China 20,000 piculs of opium a year. There would thus seem no manner of doubt that the exclusion of Indian opium from China would not affect materially the indulgence of the peoples concerned. The earnest words of the Hon. the Maharaja Bahadur of Durbhanga should be read by all persons interested in this subject (*Rept. Roy. Comm. on Opium*, 1895, vii., suppl.) and its bearings on India and the Indian people. Some few years ago the export of Yunnan opium into Upper Burma was a source of much annoyance that led to special regulations. Col. Manifold has published a vivid account of the effects of opium-smoking in Yunnan.

Exclusion of
Indian Opium.

Treaty of
Tientsin.

The Royal Commission on opium showed that the trade was simply legalised by the Treaty of Tientsin (1858). Prior to then the traffic was irregular, and disturbances were almost of constant occurrence that greatly interfered with ordinary trade. In the instructions given by the British Government to Lord Elgin there occurs the following:—"There would be obvious advantages in placing the trade (opium) upon a legal footing by the imposition of a duty instead of its being carried on in the present irregular manner." The Treaty of Tientsin was to regulate general commercial relations between China and Great Britain, and opium was only a side issue. Mr. H. N. Lay (*Rept. Roy. Comm. on Opium*, i., 84), in fact, says that in framing the Treaty, opium was not so much as mentioned, either by the Chinese or the British Commissioners. The terms of the Treaty are such that the duty by constitutional methods might be increased indefinitely or the imports prohibited. By the authorities subsequently appointed to frame regulations based on the Treaty, opium was of their own free will accepted by the Chinese as a foreign drug, that might be imported and upon which a duty was to be levied (*l.c. app.*, 137).

Convention
of Cheefoo.

Sir James Fergusson, in a debate in the House of Commons (April 10, 1891), remarked, "The Chinese at any time may terminate the Treaty on giving twelve months' notice, and to protect themselves they may increase the duty to any extent they please or they may exclude it altogether." Sir Joseph Pease, commenting on that view (*l.c.* 4), amended the interpretation of the Treaty by saying that while the Convention of Cheefoo might be recast every twelve months, the Treaty of Tientsin could only be modified every ten years. The Convention of Cheefoo simply consolidated the *Wkin* (provincial) taxes on imported opium into one common Imperial import duty, thus doing away with a source of much trouble and conflict. This was of great advantage to the Imperial Government, no doubt, and checked materially the smuggling of foreign opium through the country (*l.c. app.*, 137). A duty levied on imports was, in other words, a simpler and more effective tax than fiscal duties on the drug being carried across provincial boundaries.

CULTIVATION AND AREA OF INDIAN PRODUCTION.

D.E.P.,
vi., pt. i.,
47-55.
Cultiva-
tion.
Indian Races.

There can be no doubt that much still remains to be done in selecting stock, toward the production of desired qualities of the drug. In Bengal (Patna and Benares agencies) the plant chiefly grown is one or other of the many white-flowered races, especially that with a pale-coloured capsule (*sájed dherri*). In Malwa, on the other hand, the poppy most frequently seen has purple flowers. In the Himalaya a parti-coloured form is occasionally met with. No one, subsequent to Scott (*Manual of*

Opium Husbandry, 1877), appears to have given the subject serious attention, and the merits of the opium of India have become an accepted axiom, without the endeavour having been made to trace out how much depends on climate, soil, stock of plant, system of agriculture or purity of manufacture. Even when cultivated side by side in the garden, Scott noted that the various races which he found in the hands of the cultivators, or which he was able to select and perpetuate, yielded materially different results in quantity and quality of the drug. Nevertheless it is freely admitted that the highly valued medicinal form of opium obtained from Asia Minor is the produce of a special variety known to botanists as *glabra*. At present we possess no evidence as to whether that particular plant exists in India or could even be cultivated there. While the opium used medicinally in Europe is obtained to-day, as it appears to have been centuries ago, from Asia Minor, the opium used medicinally in India is the Indian grown and specially prepared drug obtained from *var. alba*. While in many respects the chemical nature of the two would seem widely different, Indian medical men claim that, given in the same doses, the Indian is in no way inferior to the European. [Cf. Heuzé, *Les Pl. Indust.*, 1895, iv., 91-105, 357-60; *Kew Mus. Guide*, 1907, 13.]

Plant of
Asia Minor.

Medicinal
Properties.

Area and Yield.—In modern language, "Bengal Opium" means opium manufactured at the factories of Patna and Ghazipur, and therefore grown in the provinces of Bengal, Agra and Oudh. Then again, "Malwa Opium" means opium grown in Central India, Rajputana and certain other Native States. The former class of opium is exported from Calcutta and the latter from Bombay. The area devoted to Bengal opium is accurately known; that devoted to Malwa can be ascertained only approximately, namely by estimates based on the annual exports to foreign countries. In the former, the cultivation is directly controlled by Government—a State monopoly; in the latter, by export duties only.

Area.
Bengal.

Malwa.

Control.

During the years 1872 to 1892 the area under the poppy in the British districts (Bengal opium) averaged 515,000 acres. The following were the areas returned officially as devoted to the crop for the five years ending 1901-2:—British districts, in 1897-8, 592,232 acres; in 1898-9, 602,975; in 1899-1900, 640,263; in 1900-1, 621,891; in 1901-2, 607,418. Since 1902 the net area in the Ganges valley, excluding areas on which the crop was sown but failed, has been:—1902-3, 582,807 acres; 1903-4, 642,831; 1904-5, 587,140; 1905-6, 654,928. In 1906-7 it is stated that the Government of India have decided to reduce the area to about 562,500 acres. [Cf. *Moral and Mat. Prog. Ind.*, 1905-6, 75.] In the Native States for which agricultural returns are available, the average has been about 70,000 acres. Of the British districts, approximately 200,000 acres are in Bengal, the same in Agra, and a little less in Oudh. The cultivation beyond these provinces is insignificant, and can be described as a concession practically to ancient usage or aboriginal tribes. In the Panjáb, Ajmir-Merwara and Upper Burma, for example, there have been on an average about 6,000 to 7,000 acres between them under the crop, mostly in the hill districts (Karnal, Ambala, Kangra, Shahpur, etc.). Of the Malwa production, the Native States of Gwalior, 36,378 acres; Tonk, 9,733 acres; Kotah, 31,166 acres; and Jaipur, 3,077 acres, are the published returns for 1904-5. Others, such as Baroda, Indore, etc., do not furnish particulars.

Production and Profit.—The cultivator of opium, in the monopoly Production.

roduction.

districts, is licensed and money advances made to him (if he so desires) to enable him to prepare the land for the crop in accordance with the somewhat expensive system recommended. As the advances on opium are made at the very time the rent has to be paid, they are much valued, and the profits may pay the rent of the entire holding. The cultivator is next required to deliver the whole produce at a fixed price to the Government local agents, by whom it is dispatched to the factories. The fields are surveyed when under the crop and a fairly accurate forecast of production obtained as a check on deliveries.

rice Paid.

The price paid had for some years been fixed at Rs. 5 per two pounds, but it was raised recently to Rs. 6. Still, at the former figure the value to the Bengal and United Provinces cultivators may be judged of by the fact that the average payments for some years have exceeded £1,500,000, and occasionally as much as £2,000,000. The opium is specially prepared both for the home and foreign markets in accordance with long-established custom at the Government factories. The foreign supply is sold by public auction at monthly sales which take place at Calcutta; but, in order to check speculation and steady prices, the exact amount to be offered at each sale is previously notified for twelve months. The amount to be manufactured each year is also determined beforehand, the area necessary for the production fixed, and permits issued accordingly. The opium used up in India is technically designated "Excise Opium," that which is exported being called "Provision Opium." In 1888 and some time subsequently, the estimate of required production was 57,000 chests of provision opium per annum. In 1896 the standard was reduced to 54,000 chests; and at present it is 48,000 chests. The excise opium fluctuates considerably; during the past thirty years the minimum has been 2,243 chests, and the maximum 5,554 chests. This represents the total Indian consumption, less the supplies produced within the Native States.

Check on
profits.

Most of the Native States assimilate their internal opium arrangements to those prevalent in the British districts, and, moreover, make strenuous efforts to prevent contraband dealings. Still, there must be a considerable personal traffic from the Native States into British territory. Were greater restrictions placed on the production and supply within British territory than presently prevail, illicit traffic would assume political importance and become a danger of no ordinary magnitude. As now administered, the Native States levy heavy dues on opium exported from their territories for the China market, and such opium, moreover, pays to the Indian Treasury a transit duty which in 1894 was £43½ per chest of 140 lb., in 1896 became £40, and in 1897 £33½ per chest. The decline stated in the exports of Malwa opium is attributed to Chinese production directly competing, and successfully so, with all inferior grades, none but the finest and purest Bengal opium finding a steady market. Thus at every stage the Government directly controls production and manufacture. There can be no doubt that with a commodity that bears such heavy taxation, an infinitely higher price could easily be paid to the cultivator than the amount actually received from Government, were the traffic free from all restraints and regulations. Here the first check is given by the prevention of the profits of production becoming an incentive to illicit traffic. The yield per acre may be put at from 6 to 8 seers, so that the profits of the cultivators are not materially greater than with other crops. It has been pointed out that the consumption locally of Govern-

ADVANTAGES OF THE CROP

PAPAV
O I U
Cultivation
Ben al

ment opium is much lower in opium-growing than in non-opium-growing districts—a circumstance explained on the supposition that the cultivators always retain a portion of their produce for their own consumption and that of their friends. This deduction has therefore seemed to justify the belief that an average yield of 9 seers (18 lb.) to the acre would perhaps be more like that actually attained in good seasons. Mr. W. B. Johnson of Patna, who wrote an account of the cultivation of the poppy, given as an appendix to Sir W. O'Shaughnessy's *Bengal Dispensatory* (1841, app., 749), puts, however, the yield still higher, viz. 15 seers per *bigha*, and the total value of the crop at Rs. 80. The great advantages of the crop are advances made free of interest; the wells or other permanent improvements that become possible; an absolutely certain market; no fear of sudden changes in price or demand and prompt payment for produce; while in times of scarcity and famine it is an invaluable source of income.

Yield to Acre.

Cultivation in Bengal and the United Provinces.—The opium year is considered to commence in September. It is customary to follow poppy after Indian corn or other *kharif* crops, the soil being at once taken in hand after the removal of the corn. It is ploughed at an interval of every ten days till the middle of October, when the sowing commences and may be extended to the middle of November. Land in the immediate vicinity of the village or homestead is selected for the crop on account of its being higher, usually more richly manured and more easily supervised. It requires a rich dark, sandy loam. The soil is often specially manured to the limits of the cultivator's resources—frequently 150 to 200 maunds of farm-yard manure. Penning sheep and goats on the field is regarded as one of the most satisfactory methods. Nitrate of potash is highly commended as a mineral manure. When top-dressed to the extent desired or possible, it is next partitioned off into oblong plots 6 or 8 by 4 feet for convenience of weeding and irrigation. The seed is usually specially selected from extra large or highly productive capsules. The advantage of the exchange of seed is also fully recognised, and the seed from certain localities is regarded as specially good. Still, there are no expert seed-producers, and much therefore depends on the integrity of the person with whom the exchange is made.

engal.

Seasons.

Soils.

Manure.

Selection and
Exchange of
Seed.

The day the seed is sown the land is well watered, and the next the clods on the surface are carefully broken. Six pounds are considered sufficient for a *bigha* of land (3,025 sq. yards). The seed is often soaked in water the night before sowing, and for this purpose some cultivators use a liquid manure. About a week after the plants shoot up, and when about 6 inches high the plots are weeded and thinned. Vigorous plants only are retained, and in the final condition these should not be closer than 7 to 8 inches each way.

Sowing.

Weeding.

Irrigation commences as soon as the plants appear, and resowing made in places where failure seems indicated. At regular intervals right up to the maturing of the fruit, flooding of the plots must be continued, but care has to be taken that the plants are never submerged or kept in stagnant water. Where subsoil moisture exists, watering may be delayed until December, and with certain soils may not be necessary at all.

Irrigation.

Flowering and Collection.—The plants take from 75 to 80 days until full flowering can be said to have been attained. The petals, which are four in number, are removed the third day after expansion. These are carefully preserved and are the "Flower Leaves" of the casing employed with the

provision opium. Some eight or ten days after the removal of the petals the capsules are ripe. The earliest collection of opium in Bengal is, therefore, about the end of January, and may be continued to the middle of March. In the United Provinces the seasons are a little later, flowering not being general till March and collection of the drug extended well into April, and in the hills till June. After the poppy is off the soil the land is usually left fallow till the succeeding *kharij* and is then sown with other crops, or in rare instances is highly manured and sown again with poppy. [Cf. Baden-Powell, *Pb. Prod.*, 1868, i., 295-7; Stewart, *Pb. Plants*, 1869, 10; Duthie and Fuller, *Field and Garden Crops*, 1883, ii., 64-8; Basu, *Agri. Lohardaga*, 1890, ii., 41-2; R.E.P., *Rev., Offic. Corresp. on Opium*, 1896; Mukerji, *Handbook Ind. Agri.*, 1901, 441-5; *Shahpur Gaz.*, 168-70; *Excise Admn. Repts.*]

Malwa, Panjáb, etc.—Of Malwa, for example, it has been said a mild climate, plentiful irrigation, rich soil and diligent husbandry are indispensable. The black cotton soils from which annual crops of wheat may be obtained without any manure are useless for poppy unless richly fertilised. In Baroda, poppy follows a crop of *bájra*. The following are the centres of production of Malwa opium:—In *Central India*—Indore, Gwalior, Bhopal, Bandelkhand, Baghelkhand, Malwa and Bhopawar: in *Rajputana*—Mewar, Jaipur, Haraoti and Tonk, Eastern Rajputana States, Kotah, Alwar, Bikanir and Western Rajputana States. An interesting account of *Opium in Malwa* was prepared by Mr. H. Hastings in 1895. Shahpur is the chief opium-growing district in the Panjáb, the supplies going mainly to the chief Sikh centres of Lahore and Amritsar. [Cf. Mollison, *Textbook Ind. Agri.*, 1901, iii., 245-7.]

EXTRACTION AND MANUFACTURE OF OPIUM.

The cultivation of the poppy yields several distinct and paying substances. There are (1) the inspissated sap of the green capsules—crude opium; (2) the moisture and soluble substances that drain from the opium, known as *pasewa*; (3) the poppy petals; (4) the “trash” or powder prepared from the leaves, dried stems, etc.; (5) the capsules; and (6) the oil-seed. The first-named three substances are those alone with which the Opium Department are concerned, and these, therefore, have to be dealt with here in some detail.

1. **Crude Opium.**—The green capsules are scratched in the afternoon with an instrument called the *nashtar*. This consists of four sharp blades tied together with cotton, passed between the blades so as to keep them one-thirtieth of an inch apart and allow of scratchings being made to a certain depth through the wall of the capsule and no farther. It is important that the wall of the capsule be never completely severed, but at the same time a purely superficial scratching is useless. The exact degree of penetration to ensure the best possible flow of milk requires great skill. The padding of cotton between the blades is intended to assist in this matter, since the blades can but cut up to that point when drawn at a certain angle. The incisions are usually made from below upwards, more or less perpendicularly. By modern usage this is done in the afternoon, but according to Johnson, “in the hottest part of the day, the juice as it exudes in the night may be protected by the pellicle formed in the day; the wound ought to be diagonal to prevent the juice from falling off in the night when the dews are heavy.”

Each capsule is usually lanced in this manner three or four times at

intervals of two or three days, but sometimes a single scratching may exhaust the drug, while occasionally an extra fine capsule may afford eight or even ten discharges. The opium from early sowings is thin but plentiful, and that from later sowings scanty but of a high consistence. The field is usually divided into certain portions, each taken in hand and scratched in one day, the others in succession and rotation until the entire crop has been collected. This ensures regular and systematic scratching which would not be attained by promiscuous work.

The drug formed is collected in the early morning on the day following the scratching. The juice adhering to the incisions is scraped off with a small trowel-shaped scoop of thin iron called the *setwah*. On the scoop being filled the drug is transferred to a metal or earthen vessel and conveyed to the farmer's house for further manipulation. It is stored in an earthen pan tilted to one side so as to allow the liquid *pasewa* to drain from the more solid extract. In Benares the standard of good-quality crude opium is 70 per cent. opium, 30 per cent. fluid. The *pasewa* is decanted from time to time into another vessel, and the opium turned over as occasion arises to facilitate the draining off of the *pasewa*. In the Bengal agency the standard is a little higher, viz. 75 per cent. opium, and to obtain this condition the opium is dried by being placed on a cloth tied over the mouth of an earthen pot. The required further draining away of the *pasewa* takes place, but as the cloth gets impregnated with opium it comes to possess a money value, and is purchased at the factory under the name of *kaffá* (*kaphá*). The average yield for each scarification is about 10 grains, and a healthy plant after five to eight scratchings may yield 75 grains in all.

2. *Pasewa*.—This is the dark coffee-coloured fluid (as mentioned above) that drains from the crude opium in the process of drying. The chief purpose in removing this substance is to prevent the physical depreciation which its presence effects on the drug, viz. it turns it black and makes it liquid. *Pasewa*, however, consists of the most soluble of the opium principles dissolved in dew or moisture absorbed from the atmosphere. It has a peculiar smell, is strongly acid, and contains meconic acid, resin, morphia and narcotine. It is less abundant during westerly winds or in the absence of dews at night.

3. *Leaves (Petals)*.—As already mentioned, the flowering season is January to March. But here again considerable skill is required, since if plucked off before they are ripe, the capsule afterwards contains much less opium than if the petals be allowed to fully mature. The hand is made to gently encircle the base of the flower, then drawn upwards, when, if properly matured, the petals will come away naturally. A day is selected for collection of petals when they are not moist, as otherwise they would get discoloured. The petals are then made into what is technically called "leaves." For this purpose an earthen plate is placed over a slow fire, and over it is spread a handful of petals. These are then covered over with a damp cloth and pad until the steam from the cloth causes the petals to adhere together. The thin cake thus formed is turned over and the damp pressure repeated to ensure the union of the petals on both surfaces. When fresh they have a pleasant aroma, said to be imparted to the opium for which they are subsequently employed as the packing material. There are various grades or qualities of these petal cakes recognised and sold, separately packed in specially prepared baskets. These realise Rs. 10, Rs. 7 and Rs. 5 a maund according to quality.

Lewa.

5. *Lewa*.—This is the paste used in consolidating the "leaves" in the formation of the casing employed with provision opium. It is formed of all the inferior opium and *pasewa*.

Oil.

6. *Seed and Oil*.—The best seed is obtained from capsules that have not been lanced. They yield a sweet edible oil absolutely devoid, of course, of any trace of opium, though in preparing the excise opium it is the sweet oil employed to prevent the opium adhering to the paper in which it is packed.

alwa.

Malwa Manufacture.—The systems of collection pursued in other parts of India differ almost wholly in the number of blades formed into the *nashtar*, the direction of the incisions, the method of collection and drying. The work of adulteration begins with the act of scraping off the drug from the capsules. If honestly done, the pure extract alone is removed; but if adulteration be desired, a portion of the superficial tissue of the capsule may be carried away with the drug. In Malwa the system prevails of depositing the collection of crude drug (known as *chick*) into a vessel containing linseed oil, in the proportion of one of *chick* to two of oil. This is justified from the desire to prevent evaporation. It is in reality a mode of adulteration, and the dealers refuse to purchase any opium that is thinner than half-dried glue. One acre of land well cultivated yields 70 to 100 lb. of *chick* which fetches 3 to 6 rupees a pound, so that the total crop will realise from 200 to 600 rupees to the acre.

Adulteration.

Linseed Oil.

Yield.

Subsequent Treatment.

The traders place the oil-adulterated drug in double bags suspended from the ceiling of a close and dark room, to allow of the excess oil draining off. In a month's time all the oil that can be separated is drained away. By June or July the opium is removed from the bags and thrown into large vats, where it is worked up until it attains a uniform colour and consistence. It is now made into balls of 8 to 10 oz. each, which are thrown into baskets full of a chaff prepared from the dried poppy capsules. It is then spread out on a floor covered with the "trash" or powder of the poppy leaves and stems, and there it remains until it has dried sufficiently to allow of packing, when about 150 of the cakes go to each chest. It is ready for the export market by October or November.

Engal Manufacture.—It may now be desirable to describe the stages of manipulation pursued at the Government factories in contrast with that mentioned above with the Malwa drug. The opium, as purchased from the cultivators, is first tested for purity and quality. It is then stored in large wooden boxes capable of containing 10 cwt. Whilst thus stored it deepens in colour by exposure to air and light. From this is taken the quantity that is daily to be manufactured. This is sampled, assorted, kneaded up together and thrown into boxes, certain ones being again assayed. The opium is next placed in troughs and kneaded and thoroughly mixed by men wading knee-deep in it. When uniformity by these various stages of separating, sampling, mixing and kneading has been attained, it is next day made up in cakes. For this purpose the "leaves" required, having been weighed out and damped over-night, are given to each operator along with a supply of *lewa*. The leaves, *lewa* and opium required for each cake are accurately weighed out. The operator, taking a brass cup in his hand, places the leaves within it layer upon layer, moistened with the *lewa*, until

REVENUE

he thus builds up the *shul* (a structure half an inch thick). The cake of opium, brought direct from the scales, is now inserted within, and leaf after leaf moistened in the *lewa* is inserted until the space around the cake is filled up. The layers of leaves are now brought up over the opium and compacted together until the finished cake looks like a Dutch cheese in size and shape. It is now removed from the cup and rolled in a fine powder of "trash." It is then placed in earthen cups of the size to hold it comfortably, and carried out to be dried through exposure to the sun. In this position it is retained for three days, the cakes, or balls rather, being occasionally turned round. The weight of an average cake is about 4 lb. 3½ oz., but of that fully half consists of the *shul* that surrounds it.

Encasing Shell of Leaves.

Dried.

Excise opium (known as *Abkari* opium) is inspissated by direct exposure to the sun until it attains the standard of 90 per cent., when its consistence resembles wax. It is then moulded into square bricks weighing about 2 lb. These are wrapped in oiled Nepal paper and packed in boxes furnished with compartments for the bricks.

Opium.

REVENUE AND TRADE IN OPIUM.

Consumption in India.—The excise systems of the local Governments are framed in accordance with the Opium Act of 1878. To review even briefly the various enactments and methods of fiscal administration that prevail in the various provinces of India would, however, occupy many pages. For a concise statement, mention may be made of the *Moral and Material Progress and Condition of India* (1903, 171–6). Briefly, the consumption of opium is highest in the damp malarial tracts of India, where its use is universally believed to be beneficial. It is nowhere consumed to an extent to occasion anxiety; in fact, the use of opium by the people of India, as a rule, is distinctly moderate, excess being very exceptional and condemned by popular opinion. No physical or moral degradation can be regarded as occasioned by the Indian habit, at all comparable with the use of alcohol in Europe. The mean consumption expressed to head of population in British India (including the high rate prevalent in Assam) comes to 38 grains per head per annum, and if Assam be excluded it is under 30 grains. [*Cf. Papers relating to Consumption of Opium in Brit. Burma, Rangoon Press, 1881.*]

Excise
systems.

Consumption.

To Head of
Population.

In India, opium is eaten, drunk or smoked, opium-smoking being by no means uncommon. *Madak* is the special Indian preparation smoked by the lower classes. *Chandu* is a smoking mixture made after the Chinese method, and in India is used mainly by the Chinese. Opium is, as already remarked, almost a necessity of life with certain communities, and so much faith do the people place in the drug that they by no means infrequently give it to their horses when an exceptionally heavy task has to be performed. Moreover, with the people of India the danger of accumulative action or the establishment of a craving does not seem to exist. A very large number of persons take a daily allowance throughout life, and never show any tendency to increase the amount consumed. And some of the strongest and most healthy communities, such as the Sikhs, have to be placed in this category.

Madak.

Chandu.

Daily
Allowance.

Internal Traffic.—The returns of traffic by the railways were, in 1904–5, 127,509 cwt.; in 1905–6, 130,412 cwt.; and in 1906–7, 144,255 cwt. The distribution from the provinces of production to those of consumption and to the ports of export were in 1906–7 as follows:—United Provinces, 69,574 cwt.; of which 54,057 cwt. went to Calcutta, 13,830 cwt. to Bengal,

Internal
trade.

Centres
of Production.

THE OPIUM POPPY

1,416 cwt. to the Central Provinces and Berar, and 271 cwt. to the Panjáb. The next important centre is Bengal, which exported 50,171 cwt., mainly to Calcutta. Then come Rajputana and Central India, which exported 18,500 cwt., mainly to Bombay town; and lastly the Bombay Presidency exported 2,983 cwt. to Bombay town, and these two items of Bombay town supply constitute the Malwa opium of commerce.

Revenue.

Opium Revenue.—The following statement of the opium revenue for five years may be instructive :—

—	1901-2.	1902-3.	1903-4.	1904-5.	1905-6.
<i>Receipts :—</i>	£	£	£	£	£
1. Sales (Bengal) ..	4,150,290	3,662,600	4,678,371	5,079,541	4,703,574
2. Duty (Bombay) ..	542,683	661,033	871,383	749,125	569,400
3. Sales to local Govern- ments	159,049	174,805	186,291	192,833	195,806
4. Total	4,852,022	4,498,438	5,736,045	6,021,499	5,468,780
5. Less Expenditure ..	1,608,690	1,648,483	2,225,744	1,967,085	1,892,441
6. Net Opium Cus- toms Revenue ..	3,243,332	2,849,955	3,510,301	4,054,414	3,576,339
7. Add Provincial Ex- cise Revenue on 3 ..	652,429	735,207	913,000*	991,000*	910,243
8. GRAND TOTAL ..	3,895,761	3,585,162	4,423,301	5,045,414	4,486,582

* Approximates.

The excise revenue on opium is composed of duty and vend fees. The former varies with local conditions, being highest where smuggling is most difficult. The average per seer in Assam is Rs. 28·5; in Bengal, Rs. 20·5; in Central Provinces, Rs. 13·5; in Madras and Bombay, Rs. 10; in the United Provinces, Rs. 8·8; and in the Panjáb, Rs. 3·6. Adding vend fees the average ranges from Rs. 34·9 in Assam to Rs. 11·5 in the Panjáb.

Forei n
ales.

Foreign Sales.—The number of chests of Bengal opium sold (*Fin. and Comm. Stat. Br. Ind.*, 1906, 56), and the average prices realised during the six years 1897-8 to 1903-4, were as follows :—

Year.	Number of Chests of Bengal.	Price obtained per Chest of Bengal.	Number of Chests of Malwa.
1897-1898	39,450	Rs. 1,023	18,664
1899-1900	41,700	Rs. 1,221	25,822
1900-1901	45,300	Rs. 1,361	26,007
1901-1902	48,000	Rs. 1,297	17,586
1902-1903	48,000	Rs. 1,144	20,345
1903-1904	48,000	Rs. 1,460	26,737

The actual exports from Calcutta and Bombay were :—

Canton is the chief market for the Indian opium. According to the Consul-General's Report for 1905, 75 per cent. of the drug there used comes from India. The annual average imports by Canton are about 12,000 chests, or, say, about one-fourth of the total Chinese imports. But it is ascertained that about an equal quantity of local opium is smuggled into Canton *via* Pose and the West River from Ssu'ch'uan, Yunnan and Kweichow provinces. The Chinese drug is 40 per cent. lower priced than the Indian, and can thus easily sustain all the risks incurred. According to Hosie (*Opium Trade of China*, in *Pharm. Journ.*, Nov. 10, 1906, 512-3), the average import of foreign opium into China for the ten years ending 1904 was 52,127 piculs, and in the previous decade 72,298 piculs, so that for the twenty years since 1885 the average annual decline has exceeded 1,000 piculs. The import in 1905 was 51,890 piculs, or 2,876 piculs less than in 1904. That decline, says Hosie, is due not to a decrease in opium-smoking, but to an increased consumption of the Native drug. The greatest decline occurs in Northern China, where the import has fallen from 1,735 piculs in 1895 to 690 piculs in 1905. In Central China, the decrease in 1905 was 3,740 piculs as compared with 1904. In Southern China, on the other hand, the figures show an apparent increase. In 1895 the imports amounted to 18,708 piculs, in 1905 to 25,209 piculs. It is stated, however, that these figures must not be taken to indicate an increase in consumption of the drug by the people. They are due chiefly to the fact that with the final absorption of the Native Customs in 1901 the carrying trade for opium passed to steamers and entered and paid

Imports by
Canton.

Decline of
Demand.

South
China.

duty at the maritime customs. The imports, in short, are believed to have remained stationary, and that there has only been a transfer from the Native to the Maritime Customs.

Persian Opium.

The Persian production of opium and traffic with China is seemingly assuming considerable proportions. It is grown in the central provinces and carried *viâ* Bokhara, Khokan and Kashgar, and also, more recently, by sea. The Kermanshah opium is in consequence being frequently alluded to in *Consular Reports*. The shipments in 1895 were 2,440 chests, and in 1903 they had become 4,859 chests. While often much adulterated, Persian opium has a good name in Hongkong.

Poppy seed and Oil.

Poppy Seed and Oil.—Buchanan-Hamilton (*Journ. Mysore, etc.*, 1807, i., 295-6) observes: "The poppy (*Papaver somniferum*) is plentifully cultivated both for making opium and on account of the seed, which is much used in the sweet cakes that are eaten by the higher ranks of the Natives." The seeds form a valuable article of food in the districts where poppy cultivation occurs. They have no intoxicating properties, but are better flavoured and richer in oil when taken from capsules that have not been tapped. The seeds are exported from the districts of production all over India, and are extensively employed by the sweetmeat makers or in the manufacture of certain curries. The oil obtained from the seeds is largely used for culinary purposes, the lowest grades being employed for lubrication or burning. The cake is said to be a wholesome food often resorted to by the poor, and is remarkably sweet and nutritious, and accordingly is greedily eaten by cattle. In India the oil is expressed by the cold process, the yield being about 30 per cent. In France three stages are observed:—1st, cold expression—a very superior oil used for table purposes and in the manufacture of very high-class paints; 2nd, cold expression—a lower-grade edible oil used also for paints and in illumination; and 3rd, hot expression—a much inferior oil to either of the others used chiefly in soap-making. The oil is rendered perfectly colourless by exposure to the sun. It is accordingly peculiarly suitable for mixing with paints; with white lead, for example, it forms a paint that does not readily tarnish. The price of the oil is the chief reason of its not being more extensively used in paint-making, as it is moreover a good drying oil. It is largely used by artists. Mixed with strong sulphuric acid, the rise in temperature is from 88° to 90° C. It takes about 19 per cent. of caustic potash to saponify it, and absorbs about 134 to 137 per cent. iodine.

Drying Oil.

Poppy Seed
as Food.

Prices of Seed.

Leather (*Agr. Ledg.*, 1903, No. 7, 153, 180), in an article on Indian food-grains, gives the chemical composition of the poppy seed, in which he shows it to contain 48.95 of oil, 4.07 moisture, 17.75 albuminoids, 16.99 soluble carbohydrates, 5.09 woody fibre, 6.85 soluble mineral matter, 0.30 sand, 2.97 total nitrogen, and 2.84 albuminoid nitrogen.

Price.—The average wholesale price does not appear to have changed materially for some years past. In Benares, for example, it was Rs. 47.21 per ten maunds, and in 1904 it stood at Rs. 35.6 for the same quantity. In Oudh, similarly, it was Rs. 45.57 in 1897, and Rs. 37.78 in 1904. In Ajmir it was Rs. 66.57 in 1897, and Rs. 66.56 in 1904. In Lahore, Rs. 56.08 in 1897, and Rs. 53.01 in 1904. These are fairly representative quotations—the price is higher in non-producing than in producing centres.

Trade in
seed.

Trade in Seed and Oil.—Perhaps the most significant feature of the foreign

trade in poppy seed (though an unimportant one relatively) is the fact that India imports this seed. The supply comes mainly from Persia, but during the five years 1901-6 has steadily declined from 3,858 cwt. in 1901-2 to 151 cwt. in 1905-6, nearly the whole quantity being taken by Bombay. In 1906-7 there was a slight increase on the previous year to 195 cwt. The EXPORTS are very considerable:—In 1900-1 they were 802,186 cwt., valued at Rs. 68,65,266; in 1904-5 they had expanded to 1,362,599 cwt., valued at Rs. 78,43,018; though in 1906-7 they declined to 802,615 cwt., valued at Rs. 65,77,231. The price seems to fluctuate very greatly, for while the quantity exported in 1902-3 was only 966,220 cwt., it realised Rs. 82,45,096. These exports go very largely to France, Belgium and Germany, only a very insignificant quantity to Great Britain. During 1906-7, out of the total indicated, the following were the shares taken:—France, 387,252 cwt.; Belgium, 326,038 cwt.; Germany, 88,260 cwt.; and the United Kingdom, 2 cwt.; all other countries the balance of the total. The shares supplied by the chief exporting provinces were Bombay, 526,262 cwt., and Bengal, 276,348 cwt. No figures are available for the exports of poppy-oil. The cake is chiefly employed as manure (see p. 771).

Exports.

Countries to
which Consigned.

PAP A AP A IAL.—The word PAPER is derived from *papyrus*, the name of the Egyptian reed which afforded the material chiefly used to write upon in the classic times of Europe. On this subject Prof. E. Rapson of Cambridge writes me—"There is no ancient paper (in our sense of the word) in Egypt. When people speak of Egyptian paper they mean *papyrus*."

D. P.,
vi., pt. i.,
105-
Paper.

In other parts of the world various substances have similarly been employed as paper substitutes; for example, in classic India and Central Asia, more especially with the Sanskrit people, the birch-bark (*bhuijpattra*) was, and to this day is still used for most of the purposes of paper (see p. 131). But in the moist climate of the plains of India, birch manuscripts would of necessity be very perishable, hence as a rule they are hardly more than 300 years old. As they exist they are copies of copies of copies. In Chinese Turkestan, however, manuscripts of the 3rd or 4th centuries A.D. have been found. On the plains of India, and from fairly ancient times, the leaves of certain palms have been employed for writing on. The oldest of all known Indian manuscripts are the palm-leaves found in Nepal, which belong to the 9th century A.D. The leaves most largely used are those of *Corypha umbraculifera* (*ola*, see p. 429) and *Borassus flabellifer* (see p. 170). While being written upon, the specially prepared strips of leaf are held in the left hand and the words scratched on the surface with a sharp style, the scratchings being sometimes loaded with pigment. In Assam the aboriginal tribes have for several centuries past used the inner bark of *Aquilaria A allocha* (see p. 73) as a natural writing material, a substance that not inaptly compares with the thin boards of beech-wood (the material upon which the Teutons first wrote, and from which have come the words *bece*, *boc*, *buche*, *book*). It has been said that the ancient history of China was written on finely prepared strips of bamboo, and that these were destroyed during one of the dynastic wars. It is often, in fact, affirmed that bamboo as a writing material is even more ancient than the papyrus.

Substitutes.

Ancient
Man ripts.

istory.—Stein (*Ancient Khotan*, 1907, 345) furnishes much interesting information regarding the official documents, letters, etc., found by him during his excava-

Khotan
Discoveries.

Discovery of
Paper-making.

tions of the Niya and other sites. These MSS. consist, for the most part, of two sets: (a) those written in Khotan State itself, and (b) those in China. The materials used are specially prepared strips of wood (presumed by Stein to be *Populus alba*), the older ones being in imitation of bamboo slips; next, neatly folded pages of leather; and various kinds of paper; also, more rarely, birch-bark. Bamboo slips, according to Chavannes (*Les livres Chinois avant l'invention du papier*, in *As. Journ.*, 1905, 5-75), were used in China before the discovery of paper in 105 A.D. [Cf. Raynal, *Hist. Phil. et Polit.*, 1782, iii., 146.] In fact, wood had come into use to displace bamboo, but was invariably cut to the size and shape of the older bamboo stationery. The Chinese wooden letters discovered by Stein bear out completely the tradition of the early Chinese letters. Why paper should not have reached Khotan until at least a century and a half after its discovery in China is hard to say. Whatever the cause may have been, wood was undoubtedly continued as the stationery of distant Khotan till the latter half of the 3rd century. Moreover, the early wooden letters found at Khotan are of two kinds: long, narrow and pointed (*kilamudras*), and rectangular tablets (*likitakas*), both being neatly tied up and furnished with seals. The pointed wooden letters were apparently of purely local manufacture, hence deal with local affairs, reports, official orders. The Chinese bamboo-like letters were not pointed nor furnished with seals, but they also convey official orders, and it has been established that they date from the Han epoch; in fact, one bears the actual date of 265 A.D., and is connected with the Wu-ti Emperor, the founder of the Western dynasty of China. While the imperial control of China was thus placed on the Khotan administration, it is quite clear that local self-government was to a large extent retained.

Wooden Letters.

Letters on Paper.

The letters on paper are all of a later date than those on wood. One picked up at Endere (Stein, *l.c.* 426) has been examined by Prof. J. Wiesner and determined as made of *Daphne* bark, and hence it is surmised the letter in question came from Tibet. Moreover, it was ascertained to date from early in the 8th century, and was noted to have had the surface sized and dressed with rice-water in order to render it suited for writing purposes. It may thus be regarded as marking an important advance in the knowledge of paper-making accomplished by the people of Tibet. In passing, it may be added that the further advance of sizing with gluten was not made until the 14th century. So again it may be added that a dressing with rice-water was and still is the universal practice in the manufacture of the once famed Kashmir paper, an article greatly in demand some centuries ago for making copies of the Koran. Sir Walter Lawrence points out, moreover, that this dressing allowed of passages being readily obliterated with water, and was thus objectionable.

Sized Paper.

Kashmir Paper.

Persian Paper.

Another paper mentioned by Stein (*l.c.* 307-8) dates from 718 A.D., and has been found to be written in Judæo-Persian. This is, in fact, the oldest actual example of that language known. It was written apparently by a Jew resident in Persia, and was addressed to a Khotan official. Wiesner, who apparently examined the paper of this document also, has not determined the material used—except that it was different both from the Tibetan letter and from the numerous other examples of paper presumed to be of Khotan manufacture. Stein, commenting on the absence of paper from all the older ruins explored by him, adds, "The fact itself must be considered as certain, for rich though the ruins explored by me at the Niya river site were in rubbish remains of all kinds, not one of them yielded the smallest scrap of paper. This total absence of records on paper is all the more curious in view of the political connection with China, which did not cease, as our Chinese documents plainly prove, even after the close of the Han dynasty. Nor can it be attributed to the possible want of the paper-mulberry tree (*Broussonetia papyrifera*), from the bark of which the modern paper of Khotan is extensively manufactured, seeing that the alternative use of rags, hemp and other substances was known in China from the very time of the first invention of paper (105 A.D.)." The MS. found at Dandán-Uiliq (8th century) has been identified as very possibly of Khotan manufacture, and so also those found at Kucha, which, though a little earlier (5th century), are also regarded as made of *Broussonetia* fibre. But as opposed to the idea of an ancient local industry in paper-making, there are two circumstances that seem worthy of mention in this place:—

Chinese Paper.

Paper-mulberry.

(a) None of the botanists who have collected plants in Turkestan, Mongolia, Yarkhand, Gilgit, Ladakh, Kashmir, Afghanistan, etc., appear to have seen *rous-*

sonetia, while locally made paper is sometimes spoken of as procured from other indigenous plants, such as a species of *Desmodium*.

(b) The material of the Bower, Macartney and Godfrey *Manuscripts* was found by Wiesner (*Denkschr. Akad. Wiss. Wien. Math.-Nat.*, 1902, lxxii., 1-50) to be usually a mixture of fibres in which *Behmeria* (ramie) and *Broussonetia* (paper-mulberry) were the chief. These MSS., being for the most part in Sanskrit, were not likely to have been written in China, while the presence of ramie fibres in their fabrication precludes all idea of having been made in Khotan or anywhere in East Turkestan.

Rhea Paper.

Wiesner, reviewing the information to hand regarding the paper-mulberry tree, says that in Japan the fibre has been used for the manufacture of paper since the 6th century of our era, but earlier still in China. The Chinese use the young shoots of the bamboo in paper-making. [*Cf. Karabacek, Das Arabische Papier*, 29.] Prof. Giles (in a letter to Wiesner) remarks: "The earliest paper (in China) was made from tow, old linen, fishing-nets, etc. Modern paper is made from bamboo fibre, the bark of the *Broussonetia papyrifera* and rice straw. I can find no record of different papers at different periods. It is expressly stated that in Ssu'ch'uan hemp was used for making paper, in Fukhien bamboo, in the north mulberry bark, in Kiangsu rattan, on the sea coast lichen, in Chahkiang husk of grain, in Central China silk and in Hupeh *Broussonetia papyrifera*, vide the *Pen tsoa kang mu*, or *Materia Medica*." The MSS. discovered by Stein at Khotan thus prove that paper manufacture was very possibly known and practised in Persia, Central Asia, Tibet and China many centuries before the art was known in Europe.

Bamboo Shoots

Rags.

There is no very certain knowledge when the art of paper-making came to India. It is not mentioned by any trustworthy writer until the 14th or 15th century. Recently it has been affirmed in the Indian public press that paper-making was practised at Sialkot 620 years ago. Marco Polo, towards the close of the 13th century, was one of the earliest authors who made known the fact that the Chinese issued paper money, the paper being prepared from the bark of the mulberry. [*Cf. Travels* (ed. Yule), i., 378.] Kublai Khan had paper-money made in Peking about 1260 A.D., and thus about the time when paper, as we now understand it, was first made known in Europe. Polo, therefore, expresses no astonishment at the material paper, but simply at the fact of its being accepted in place of gold and silver. John Ray (*Hist. Pl.*, 1688, ii., 1302) mentions that the art of paper-making was introduced into Germany from Galicia in 1470 A.D., and he gives a description which is interesting from the fact of its being supposed to have been new and instructive at the time when penned.

Indian Know-ledge.

Nicolo Conti, who visited India in the early part of the 15th century, says, "The inhabitants of Cambay alone use paper; all other Indians write on leaves of trees, of which they make very beautiful books. But they do not write as we, or the Jews do, from left to right or right to left, but perpendicularly, carrying the line from the top to the bottom of the page" (Winter Jones, transl.; also in ed. Hakl. Soc., 1857, 31). A little later Abd-er-Razzak, Ambassador from Shah Rukh, visited India in 1442 A.D., and, like Nicolo Conti, went to Bidjanagar (Vijayanagar), the capital then, as he says, of the mightiest kingdom on earth. To-day that great city is a vast ruin, no part of it inhabited, and palaces and public buildings that were in process of erection are left as if the stone-workers had but gone for their midday meal.

Cambay.

Vijayanagar.

"The writing of this people, says Abd-er-Razzak, is of two kinds: in one they write their letters with a *kalam* of iron upon a leaf of the Indian nut (the cocoa-nut tree)." "These characters have no colour and the writing lasts but a short time. In the second kind of writing they blacken a white surface; they then take a soft stone, which they cut like a *kalam* and which they use to form the letters; this stone leaves on the black surface a white colour, which lasts a very long time, and this kind of writing is held in high estimation."

It is customary to read that paper-making was introduced into Hindustan from Kashmir in the 16th century about the time of the Emperor Akbar. Lawrence (*Valley of Kashmir*, 379) tells us that Kashmir was once famous for its paper, which was in much request in India. It was made from rags and hemp fibre sized with rice-water. He then adds that it is believed the art was introduced from Samarkand. It is often said the Arabs learned the art on the capture of that city and thence in due time carried it to Spain. So also Gibbon mentions that the knowledge of paper-making from linen rags was diffused from Samarkand, and Cassire is of opinion that it reached Mecca in the year 710 A.D. It is,

Kashmir Paper.

Arab Knowledge.

Nepal Paper.

however, highly likely that Nepal was possessed of the same knowledge, and that both States may have derived their skill from Tibet or China; and it is certain (from Nicolo Conti and others) that paper was used in India at least a century prior to Akbar's time. Pietro della Valle (*Travels, etc.*, 1623 (ed. Hakl. Soc.), ii., 291) speaks of books being written on palm-leaves at Mangalore, "not on paper," and Thevenot (*Travels in Levant, Indostan, etc.*, 1687, pt. iii., 90) also mentions that palm-leaves were used by the Malabars as a writing material. But Ovington (*Voy. to Suratt*, 1689, 249), less than a century after Akbar's time, gives so vivid a picture of the merchant's account books that it is difficult to realise that he is speaking of fully two centuries ago. "The paper-books," he says, "in vulgar use among the Inhabitants of India, on which they write, are long Schrowls of Paper, sometimes Ten Foot in length, and a Foot broad, sewed together at the upper end, as many long Sheets as the occasion of the Writing requires. The Pen they write with is the ancient *Calamus* or Reed, about the thickness of a large Goose Quill. And some of their Standishes are made long and square and above an Inch broad and of sufficient length to contain both Pens, and a place for Ink." He then describes the manner of writing obliquely and down the long pages in such a fashion as to explain Nicolo Conti's statement of the Indians writing from the top to the bottom of the page. Ovington expressly says that the Indian writing is not like the Chinese, in straight lines downwards, but "from the uppermost corner of the left to the lowermost corner of the right." The long page of the books, however, was doubtless the idea that inspired Nicolo Conti. But Ovington goes on to say that the paper used in India "by its Slickness and Smoothness appears shining, which is of ordinary use; but that which they write upon, either to the Emperor or Persons of consequence is gilt all over the surface, as ours is on the Edges."

San Hemp Paper.

Ironside published in 1774 (*Phil. Trans.*, lxiv., 99; abridg. ed., xiii., 506) an interesting account of the Indian paper manufacture practised in his day. The material was *san* hemp (*Crotalaria juncea*), but for paper-making "old ropes, clothes and nets, made from the *san* plant" were preferred to fresh fibre, presumably because of their cheapness. These *san* rags were cut up into small pieces, macerated in water for a few days (generally five), washed in the river in a basket, and thrown into a jar of water lodged in the ground; the water being strongly impregnated with a lixivium of "*sedgi-mutti*" (crude carbonate of soda) six parts, and quicklime seven parts. "After remaining in this state eight or ten days, they are again washed, and while wet broken into fibres, by a stamping lever, and then exposed to the sun, on a clean terrace, built for this purpose; after which they are again steeped in a fresh lixivium as before. When they have undergone three operations of this kind they are fit for making coarse brown paper; after seven or eight operations, they are prepared for making paper of a tolerable whiteness." The pulp thus produced is taken up on a fine-wire frame just as in the English manner.

Burmese
Parabaik.

Nisbet (*Burma under Brit. Rule and Before*, 1901, i., 386) says the Native manufacture is now confined mainly to "the preparation of *parabaik* or paper-slates used at the monasteries, and of umbrellas." "The inner fibre of soft bamboo shoots or the bark of the *mahlaing* or paper-mulberry (*Broussonetia papyrifera*) being pounded into a pulp with water, and half its weight of lime being then added, it is boiled with water until nothing but the pulp is left. This is pounded and spread thinly over a coarse cotton muslin framework, and allowed to dry in the sun. It now forms a rough grey parchment, about a cubit in breadth, which is folded up in alternating folds of about nine inches wide. When coated with finely powdered charcoal dust mixed in glutinous rice-water it is ready for being written upon with pencils of steatite or soap-stone." The use of paper in the manufacture of Burmese umbrellas is an important branch of the local industry, but unfortunately the artistic indigenous paper umbrella is rapidly being displaced by the cheap European article, and the making of the special umbrella paper is accordingly rapidly becoming a thing of the past. The Burmese system of writing on black-coloured pasteboards (*parabaik*) recalls Abd-er-Razzak's story of the people of the now lost empire of Vijayanagar (see above), who wrote on black surfaces with a soft stone. The supposed close affinity of the Telegu people to certain of the Burmese races gives an interest to this curious circumstance that it might not otherwise be supposed to possess. In Japan, paper-making is very ancient and the plant chiefly used is (as in Burma) the paper-mulberry. The reader will find Rein's account of Japanese paper-making most instructive (*Indust. of Japan*, 1889, 393-419).

Paper
Umbrellas.

Japanese Paper.

Paper Manufacture.—The Native art of paper-making in India to-day is very much like that of glass-blowing: it consists in re-making waste paper. In a country teeming with fibres, it is surprising that the question of a good paper material has not been satisfactorily determined. And this theme seems to be constantly revived by residents in Europe who overlook the immense size of India. A few hundred miles are of little concern in most questions, but with paper-making transit freights soon kill the prospects of supplies. Then again the cost of land near the centres of trade where paper mills are usually built, precludes the special cultivation of paper stuffs. Moreover, as paper fibre, like esparto, must be fit for almost immediate immersion in the vats, paper-making can never pay the cost of separation and preparation, however simple and inexpensive. No fibre known to commerce can compete with jute in point of cheapness, yet the paper-makers can afford to purchase jute waste and jute cuttings only, so that but for the demand for an altogether different purpose the paper-maker could never procure jute at all.

The two most important paper grasses in India are *bhabar* (*Ischænum*, p. 694) and *munj* (*Saccharum*, pp. 929–30). These are now being largely used by the Indian steam-power paper mills, the supply at a remunerative price being the chief obstacle to their further utilisation. It has been demonstrated that bamboo (pp. 108–10) affords an excellent paper, but practical difficulties exist such as the cost of the chemicals required, and the fact that the wholesale removal of the young shoots, which alone are serviceable, injures the stock. It accordingly has to be added that, at present, the most valuable paper materials in India after *bhabar* and *munj* are old rags, waste gunny bags, waste jute and *san* ropes, old paper, etc.

Whatever may be the source of the cellulose, it has to be reduced to pulp, and in most cases bleached. If rags are used, a preliminary dusting is essential. The material is then boiled with alkalis; in the case of grasses, such as esparto, a 10-per-cent. solution of caustic soda under a pressure of 10 to 50 lb. of steam is required. The pulp thus obtained is then washed to free it from the residuary alkalis, thoroughly pulped mechanically, then loaded with the mineral sizing material and coloured as desired. This is known as the *magma*, and to convert it into paper a fine wire cloth is passed through the trough containing liquefied pulp, when a film of the required thickness is made to adhere and is removed. This is then compressed by being passed between rollers and, if so desired, is sized with gelatine, and lastly dried off by being passed between heated rollers or colanders.

[Cf. Morris, *Cantor Lect.*, Soc. Arts, 1895; Cross and Bevan, *Textbook of Paper-making*, 1900; Blount and Bloxam, *Chem. for Engin. and Manuf.*, 1900, 344–7; Julius Habner, *Cantor Lect.*, 1902–3; *Chem. Appl. to Arts and Manuf.*, vii., 513–42; Clayton Beadle, *Chapters on Paper-making*, 1904, i.; 1906, ii.; Hanausek, *Micro. Tech. Prod.* (Winton and Barber, transl.), 1907, 92–4; Stuhlmann, *Halfa-Gras oder Esparto für Deutsch-Ostafrika*, *Der Pflanze*, 1907, No. 15–7.]

Paper Mills.—The first works for the manufacture of paper organised in England date from 1588, and these were established at Dartford in Kent by a German jeweller, John Spielman, who was knighted by Queen Elizabeth. A century previously similar works had been erected in Spain. So late as 1690 coarse brown paper only was made in England, the supplies of the finer white papers being obtained from France and Holland. The war with France occasioned such a rise in duty that a stimulus was given for the improvement of home production. But an

Capital.

Act of Parliament had to be passed before the desired improvement became possible. The first white paper made in England was produced by a Mr. James Whatman of Maidstone. Soon, however, England made rapid progress, but so late even as 1801 English paper was entirely hand-made.

The first occasion on which cotton was used in England was in the manufacture of paper. Cotton paper superseded the more expensive parchment of previous dates. Mention is made of cotton paper in 1102 (Macpherson, *Ann. Comm.*, 1805, i., 315 (many passages)). It is often affirmed that linen paper appeared before that from cotton, but there is no very satisfactory proof of that opinion, though it is quite likely that the discovery of pulping fibrous materials may have led to the use of linen and cotton almost simultaneously. [*Cf. Yates, Text. Antiq.*, app. A., 383-8.] One of the earliest detailed accounts of the Native methods of paper-making in India is perhaps that given by Buchanan-Hamilton (*Stat. Acc. Dinaj.*, 272-3), the material used being jute. Prior to 1840 India obtained a large share of its paper supplies from China. About that date interest was aroused in the subject, and both Hindu and Muhammadan factories for hand-made papers were established all over the country. During Sir Charles Wood's tenure of the office of Secretary of State for India, an order was issued for the purchase of all the supplies required by the Government of India in Great Britain, and this threw back very seriously the growing Indian production.

It is not very certain when paper mills were established in India. The expression "Serampore Paper" is used all over India for a particular class of Native-made white paper. Mr. D. M. Traill wrote, some years ago, an interesting account of paper-making in which he reviews briefly some of the historic facts, especially the chief grades of paper and firms concerned in their production (*Ind. For.*, 1891, xvii., 322-30). He there tells us that the capital engaged in the paper trade is nearly fifty million pounds, of which three-fourths represent plant and one-fourth working capital. He then concludes with a brief notice of the Indian mills, in which he refers to the fact that a paper mill in Serampore was the pioneer, and adds, "we well recollect seeing the silent and rusty machinery as far back as 1864."

"There are eight paper mills in operation—three in the Bombay Presidency, four in Bengal, and one at Lucknow. Of the eight, two are private concerns in the Bombay Presidency, one of which has stated the capital invested. So far as information is obtainable, the total capital invested amounts to Rs. 67,33,000 (of which Rs. 57,63,000 are paid up), besides Rs. 11,07,650 debentures, and shows a decrease of 6 lakhs, compared with 1902, owing to the reconstitution of the Imperial Paper Mill at Kankinara as a branch of the Titagarh Paper Mills Company, Ltd. Most of the white and blue foolscap and much of the blotting paper, note-paper, and envelopes used in the Government offices are now obtained from the Indian mills. The total quantity of paper made in 1904 was 45 million pounds, and its reported value Rs. 61,49,446. The mills employ 4,266 persons. The capital employed has been doubled in twenty years since 1885, and the production and number of persons employed have increased about fourfold. Two of the larger mills in Bengal have paid no dividends for five years, as they have been unable to compete successfully with the cheap wood-pulp paper of attractive appearance which is

largely imported from Europe" (*Fin. and Comm. Stat. Br. Ind.*, 1906, lix.).

Trade.—Internal.—The total transactions by rail and river in paper and pasteboard amounted in 1906–7 to 457,355 cwt. The chief exporting centres were the Province of Bengal, 214,137 cwt.; Bombay sea-port, 87,116 cwt.; Calcutta, 61,121 cwt.; Madras ports, 31,530 cwt.; the United Provinces, 26,109 cwt. The chief importing centres were Calcutta, 160,162 cwt.; the Panjáb, 80,559 cwt.; United Provinces, 40,530 cwt.; Bombay, 37,916 cwt.; Bengal, 21,936 cwt. By coast, the returns are given in rupee values. In 1906–7 the exports were valued at Rs. 11,69,758 and the imports at Rs. 9,05,237. Bengal exported paper to the value of Rs. 11,56,510; while Madras imported to the value of Rs. 6,50,297, Bombay, Rs. 2,09,866, and Burma, Rs. 20,124.

External.—The EXPORTS from India of manufactured paper amount to little. For the period 1900–7 the total value of manufactured papers of all sorts, including pasteboard, was as follows:—1900–1, Rs. 78,227; 1901–2, Rs. 53,658; 1902–3, Rs. 42,903; 1903–4, Rs. 26,781; 1904–5, Rs. 28,350; 1905–6, Rs. 13,703; 1906–7, Rs. 6,607. In 1906–7 the total was made up thus:—printing paper, Rs. 5,883; writing paper and envelopes, Rs. 167; other kinds, Rs. 507; pasteboard, Rs. 50. Almost the whole of the printing paper, writing paper and pasteboard go from Bengal, and ordinarily of other sorts also, but in 1904–5 Bombay supplied the largest share of writing paper. During the same period the export of rags and other materials for paper manufacture showed the following returns:—1900–1, 21,683 cwt., valued at Rs. 70,833; 1901–2, 26,321 cwt., valued at Rs. 67,840; 1902–3, 13,431 cwt., valued at Rs. 46,490; 1903–4, 9,077 cwt., valued at Rs. 34,705; 1904–5, 10,248 cwt., valued at Rs. 29,543; 1905–6, 19,831 cwt., valued at Rs. 83,870; and 1906–7, 12,581 cwt., valued at Rs. 67,412. India also re-exports quantities of manufactured paper, and in 1906–7 these were valued at Rs. 76,614.

The IMPORTS of paper, on the other hand, are large, and in late years show a slight increase. For the period 1900–7 they were valued as follows:—1900–1, Rs. 45,29,996; 1901–2, Rs. 52,71,634; 1902–3, Rs. 52,48,058; 1903–4, Rs. 52,18,396; 1904–5, Rs. 64,37,288; 1905–6, Rs. 70,48,978; and in 1906–7, Rs. 80,11,105. In 1906–7 the total was made up thus:—printing paper, Rs. 28,33,632; writing paper and envelopes, Rs. 22,66,714; other kinds of paper, Rs. 25,75,366; pasteboard, Rs. 3,35,393. The largest quantities come from the United Kingdom, and in 1906–7 these were valued at Rs. 44,06,312; from Germany, Rs. 15,82,445; Austria-Hungary, Rs. 7,04,525; and Belgium, Rs. 6,66,638. In the same year the imports of rags and paper materials were valued at Rs. 8,173.

As showing the value of esparto grass as a paper-making material, it may be mentioned that Messrs. Ide & Christie, in their monthly circular of September 16, 1907, show that for the years ending August the imports received by Great Britain of that grass were in 1905, 198,508 tons; in 1906, 186,242 tons; and in 1907, 192,809 tons. Needless to say, India imports no esparto. The British supply is mainly Spanish, Algerian, Tunisian and Tripoli, and the prices shown range from £3 2s. 6d. to £5 2s. 6d. per ton.

Paper Materials.—As already set forth, the chief considerations in the selection of paper materials are cost at the mill and constancy of

supply. The chief materials are accordingly rags of linen or cotton esparto, *munj* and *bhabar* grasses; flax in the form of spinners' waste; hemp in the form of fragments of used rope; wood; straw; jute waste and old paper remade. Hanausek (*Micro. Tech. Prod.* (Winton and Barber, transl.), 1907, 100-2) gives the following paper fibres:—linen rags, hemp, cotton rags, jute, straw, esparto, maize, *juár*, wood, etc.

Felted Fabric.

Paper (as may have been inferred from the brief account of manufacture given above) is literally a felted fabric composed of vegetable cellulose fibrils. When the fibrils, of which it is proposed to be made, are cemented together as in wood, they must be liberated and the raw material thus reduced to the condition known as "half stuff," and finally "pulp." In this condition, when floated out in water, allowed to settle over a frame and the water drained away, the felting of the fibrils takes place and paper is formed. Obviously, therefore, the less bulky the raw material the cheaper its transport to the mill. From this point of view, the advantages are entirely on the side of wood; it is compact, can be transported easily, more especially if a waterway connects the forest with the mill, and requires no expensive storage. But the pulp obtained from wood is of a very different nature from that of cotton rags, so that the purpose for which the paper is to be used comes in as a governing factor in the selection of the crude material.

Wood Pulp.

Rags.

The following are some of the chief materials used in the manufacture of paper in India:—

Adansonia digitata.	Helicteres Isora.
Agave sp.	Hibiscus cannabinus.
Antiaris toxicaria.	Isch um angustifoliu .
a buse .	usa sp.
roussonetia papyrifera.	puntia Dillenii.
Corchorus sp.	Ph nix paludosa.
Crotalaria juncea.	accharu arundinaceum.
Daphne cannabina.	ansevieria zeylanica.
edgeworthia Gardneri.	

Chief Indian
Materials.

Several of these will be found discussed in their respective places in this work; for the others the reader is referred to the *Dictionary* (vi., pt. i., 107-9). The chief ones are *Ischaemum* and *Saccharum*, but with the Native paper-makers of the plains of India, the *san* hemp (*Crotalaria*) and the hemp-leaved *Hibiscus* are the most important, and on the hills, *Daphne* and *Edgeworthia* afford the so-called Nepal paper. Sir W. Thiselton-Dyer (*Kew Bull.*, 1888, 81-4) was instrumental in drawing attention to the fact that in Siam the bark of the tree *Streblus asper* is employed in the fabrication of Native paper. The tree is plentiful in many parts of India. (See *Alkaline arths* (pp. 55-6, 58); *Acacia Jacque ontii* (p. 15); *Agave* (p. 43); *Aquilaria* (pp. 73-4); *Alpinia* (p. 60); *Caryota* (p. 286).)

The kodo, kodon, kodam, kodra, kodoá dhan, janhe, harih, pakodi, menyá, kiraruga, etc. An erect annual grass, native of India, extensively cultivated during the rainy season.

Area.

Area.—Returns under this crop are available only for Bombay, where in 1905-6 there were 204,022 acres, chiefly in Gujarat, Katnágiri, the Uplands of the

Konkan and the Ghát parts of the Deccan. In the Central Provinces the area occupied is believed to be greater than in any other part of India, but it is not returned separately. Together with *kutki* (*Panicum miliare*) it occupied, in 1904-5, an area of 2,039,345 acres. In the same year in the United Provinces, *Paspalum* and other small millets covered 1,939,753 acres. In *Field and Garden Crops* it is stated to be grown more extensively than any other millet in the United Provinces, and over a large portion of these provinces it is the favourite crop for inferior outlying lands. This is chiefly on account of the readiness with which it grows on the poorest of soils, not on account of the quality of the grain. Sowing takes place at the commencement of the rains, at the rate of 12 to 20 lb. seed to the acre, and the crop is cut in October. It is either grown alone or (in the Doáb) mixed with cotton, and in the Benares Division with *dal* (*Cajanus*). Careful weeding is required to secure a good outturn, which is estimated at 10 to 12 maunds per acre.

Poor Soil.
Seasons.

Cultivation.—Of Bombay, Mollison (*Textbook Ind. Agri.*, 1901, iii., 64-7) observes that the crop is important in the *gorádu* soils of the Kaira district and similar alluvial soils in Baroda. It is never grown alone in Gujarat, the usual mixture being *tuver* (*Cajanus indicus*), *tal* (*Sesamum indicum*), and *ambádi* (*ambári*) (*Hibiscus cannabinus*). If properly manured, the mixture may be grown year after year in the same field. In low-lying damp fields rice and *kodra* are grown together, the mixture being known as *vagadu*. In preparatory tillage the bladed harrow (*karab*) is used to loosen the surface soil and prepare a friable, shallow seed-bed. The seed is furrowed with the three-coultured drill (*tarfin*), and the seed is mixed before sowing in about the following proportions:—12 lb. *kodra* : 2 lb. *tuver* ; $\frac{1}{2}$ to $\frac{1}{2}$ lb. *tal* ; $\frac{1}{2}$ lb. *ambádi*. After sowing, the field is levelled, and the crop should subsequently be weeded once in about a month or six weeks and bullock-hoed two or three times. It is ripe early in October, and reaped with a sickle, tied into bundles, and threshed by bullocks in the usual way. Mollison gives the outturn of a good Kaira crop as follows:—*kodra* (12 lb. seed), 985 lb. grain per acre, 1,304 lb. straw; *tuver* (4 lb. seed), 265 lb. grain per acre, 232 lb. straw; *tal* ($\frac{3}{4}$ lb. seed), 130 lb. grain per acre. The cost of cultivation he estimates at Rs. 23 per acre.

Cost.

Though used as Food by a large number of people in India, the grain cannot be considered a wholesome article of diet, and in some seasons contains a poisonous narcotic principle. In Gujarat the poisonous and non-poisonous grain are known in the bazárs as *mitha* and *mina* respectively. Damp cloudy weather towards harvest time, a damp season and damp soil are said to produce poisonous *kodra*. Leather (*Agri. Ledg.*, 1901, No. 10, 370; 1903, No. 7, 151, 180) gives the following analysis of the grain:—moisture, 8.01; oil, 3.36; albuminoids, 5.81; soluble carbohydrates 70.06; woody fibre, 8.47; soluble mineral matter, 1.34; sand and silica, 2.95; total nitrogen, 1.00; albuminoid nitrogen, .93. [*Cf. Church, Food-Grains of Ind.*, 1886, 39-40; Basu, *Agri. Lohardaga*, 1890, pt. 2, 29; *Pharmacog. Ind.*, 1893, iii., 619-20; Rice, *Mysore Gaz.*, 1897, i., 117-8; Mukerji, *Handbook Ind. Bájra.

CULTIVATION.—Though grown to a less extent than *juár* (*Sorghum vulgare*), its cultivation is geographically very similar and comprises extensive tracts in Northern, Western and Southern India. The following were the acreages in British India during the three years ending 1905-6:—14,137,482 in 1903-4; 10,369,765 in 1904-5; and 11,630,710 in 1905-6. In the Native States:—1,382,473 in 1903-4; 1,305,446 in 1904-5; and 893,949 in 1905-6.

Important Crop.

ating between 30,000 and 60,000 acres. According to Mukerji (*Handbook Ind. Agri.*, 1901, 259) it is grown on poor, free, dry, sandy soil. Village refuse is sometimes used as manure, but no irrigation is required. It is sown at the end of July at a rate of 6 to 10 lb. seed per acre. Harvesting takes place in October and November, and the outturn of grain amounts to from 300 to 500 lb. per acre.

United Provinces.—The area in 1905–6 amounted to 1,792,526 acres in Agra and 372,848 in Oudh. In Agra the largest areas occur in Budaun, 200,643 acres; Agra, 166,787 acres; Moradabad, 166,014 acres; Etah, 113,936 acres; Allahabad, 95,903 acres; Shahjahanpur, 99,049 acres; Bareilly, 87,746 acres. In Oudh, Hardoi, 130,771 acres; Unao, 59,738 acres; Sitapur, 47,884 acres; Lucknow, 36,588, acres, etc. According to Duthie and Fuller it is a *kharif* crop, sown a little later and reaped a little earlier than *juar*; it is accordingly a useful substitute when sowing has been delayed through floods or failure of the rains until *juar* is impossible. It is rarely sown alone, but generally mixed with the same minor crops as are grown with *juar*, except that *mung* (*Phaseolus radiatus*, Linn.) is usually replaced by *moth* (*P. aconitifolius*). It generally occupies poor, light soil, and requires less rainfall than *juar*. It is never manured and rarely irrigated. The land is ploughed one to four times and the seed (mixed with that of the subordinate crops) sown at the rate of 2½ to 3 seers per acre. There should be at least one weeding. The grain ripens towards November, when the heads are cut off and carried to the threshing-floor. The cost of cultivation is estimated at Rs. 9–8a. per acre, and the outturn varies in different localities from about 5½ maunds of grain to 7 maunds, and the outturn of dry fodder about 30 maunds. [Cf. *Agri. Ledg.*, 1895, No. 17,233; Nevill, *Dist. Gaz. U. Prov.*; *Cawnpore Exper. Farm Repts.*]

Central Provinces and Berar.—The area in 1905–6 was 40,608 acres in the Central Provinces and 55,188 acres in Berar. In the former:—Nimar, 22,146 acres, and Narsinghpur, 11,470 acres; and in the latter cultivation is almost entirely in Buldana with 46,080 acres.

Rajputana and Central India.—The crop is grown largely in the Native states, especially in Alwar, where in 1905–6 the area was 221,604 acres; Bharatpur, 193,465 acres; Gwalior, 184,426 acres; Marwar, 165,692 acres; Jaipur, 79,093 acres; Mysore, 39,944 acres. In Ajmir-Merwara the area was 32,043 acres. The crop is sown at the same season as barley (June–July), and on dry lands only. The average yield is stated to be 1.73 cwt. per acre. [Cf. Watson, *Rajputana Dist. Gaz.*, 1904, i., A., 46, 56.]

Panjáb and North-West Frontier.—*Bajra* is largely grown in the districts of the Panjáb, and in the dry elevated tracts south of Rawalpindi it constitutes the principal *kharif* crop. In 1905–6 the area was 829,269 acres. The largest shares are as follows:—Jhelum, 108,684 acres; Gujrat, 103,624 acres; Rawalpindi, 94,766 acres; Attock, 68,357 acres; Gurgáon, 66,091 acres; Hissar, 64,345 acres; Sháhpur, 55,746 acres; Delhi, 21,016 acres; Rohtak, 13,219 acres. In the North-West Frontier the area was 71,355 acres, mainly in Kohát. During the year under review the area seriously declined. In the districts of Hissar, Rohtak, Gurgáon, Delhi and Karnál it fell from 1,135,674 in 1904–5 to 169,116 acres in 1905–6. The average yield for the year 1901–2 was 407 lb. per acre in the Panjáb, 402 lb. in the North-West Frontier. In Dera Gházi Khan it is the most important crop after wheat, and in the Rawalpindi district it is the staple of the autumn harvest. It thrives everywhere in the plains at the base of the Salt Range, and in untoward years is usefully replaced by *til*

THE SPIKED MILLET

P N I T U
TYP OI U
Cultivation

(*Sesamum indicum*) or some of the pulses. In the Karnál district it thrives best on a sandy soil, and is thinly sown after the first rainfall, mixed with the seed of some small pulse. In Kohát it is sown between April and August, and is the principal *kharif* crop on the *barani* (i.e. unirrigated) lands of the district. The crop is generally cut in October. In the Bannu district it is largely grown on the stiffer *thal* soils. It is sown at the rate of 2 to 5 seers per acre from the middle of March to end of July. The first-sown crops ripen about the middle of August, and ears are plucked as they ripen till early in December. [Cf. *Dist. Gaz. Panjáb*; *Settl. Repts. Panjáb*.]

Seasons.

Bo bay and Sind.—The area in 1905-6 was 4,354,437 acres in Bombay and 867,406 acres in Sind. In Bombay the largest areas were :—Ahmadnagar, 904,590 acres; Nasik, 808,469 acres; Poona, 681,413 acres; Khandesh, 583,686 acres; Satara, 366,940 acres; Bijapur, 340,560 acres; Kaira, 218,159 acres. In Sind, Thar and Parkar, with 406,033 acres, and Hyderabad with 338,221 acres, are the chief localities.

ombay.
Areas.

Mollison says it is entirely a rain crop, occupying the lighter description of soils in all districts of moderate rainfall. The crop does best when the climate is moderately dry and when the monsoon comes in downpours, with plenty of sunshine between the showers. Except in parts of Khandesh it is always a mixed crop, and as such may be grown continuously on the same land. But rotation is also frequent. In the lighter soils of Khandesh it is considered a good preparation for *varádi* cotton. In the sandy soils of Kaira, Ahmadabad, etc., it is rotated with *kodra* (*Paspalum scrobiculatum*), *sundhia* (*Sorghum bicolor*), *juár* (*Sorghum vulgare*), etc. In the light soils of the Deccan it is rotated with *juár*, niger-seed, etc. In the Deccan the subordinate crops with *bájra* (= *bájri* in Bombay) are, separate rows of *tur* (*Cajanus indicus*) and a sprinkling of *udh* (*Phaseolus Mungo*, Linn.), *math* (*P. aconitifolius*), *kulthi* (*Dolichos biflorus*), *ambádi* (*Hibiscus cannabinus*), etc. In Gujarat the most common subordinate mixture is perennial *rozi* cotton in rows and *math* in amongst the *bájri*, but two or more of the following may also form subordinate crops, viz. *mag* (*Phaseolus radiatus*, Linn.), *chola* (*Vigna Catjang*), *guvár*, *tur* or *tuver* (*Cajanus indicus*), *sesamum* and *sheria* (*Hibiscus cannabinus*).

Soils.

Rotation.

Mixed
Cultivation.

In Gujarat the land should be ploughed two or three times after the first fall of rain, then left for some time. The field should again be ploughed shortly before sowing. Sowing takes place between 1st and 15th of July. The seed-rate mixture recommended is as follows :—*bájri*, 6 lb. per acre; *guvár*, 1 lb.; *math*, 1 lb.; *mag*, $\frac{1}{2}$ lb.; *sesamum*, $\frac{1}{2}$ lb.; *ambádi* or *sheria*, $\frac{1}{2}$ lb.; *tuver*, $1\frac{1}{2}$ to 2 lb. All are mixed together before sowing, except *tuver*, which is sown separately in every fourth row. The seed is drilled in rows about 15 inches apart, and the surface then levelled. When the seedlings are about 6 inches high, the crop is bullock-hoed and hand-weeded, and again when 2 feet high. A crop sown in early July will be ripe the beginning of October. It is reaped with a sickle close to the ground, left lying in the field for several days, and then stacked.

Ploughings.

Drill Sown.

Seasons.

Yield.

Cost.

Mollison gives the following outturn (grain, seed or by-product) from a well-managed field in the Kaira district :—*bájri*, 900 lb.; *math*, 120 lb.; *guvár*, 80 lb.; *sesamum*, 60 lb.; *sheria*, fibre. The cost of cultivation he estimates at Rs. 26-1a. per acre. [Cf. *Crop. Exper. Bomb. Pres.*; Mollison, *Textbook Ind. Agri.*, 1901, iii., 18-23.]

adras. Areas.	Madras and Mysore. —The total area in 1905–6 was 3,004,717 acres in Madras and 39,944 acres in Mysore. In Madras the largest areas occur in Coimbatore, 580,299 acres; Salem, 376,257 acres; Cuddapah, 341,311 acres; South Arcot, 276,284 acres; Guntur, 255,511 acres; Trichinopoly, 173,721 acres; North Arcot, 133,643 acres; Madura, 164,194, etc. In Mysore, Chitaldrug had 33,448 acres.
Soils.	In the Godavari district it is grown on <i>regada</i> , <i>lanka</i> and sandy soils. The ground is manured in March by penning cattle or sheep on it, and in May it is ploughed twice every six days for three weeks. The ground, both then and at the time of sowing, should be moist. The seed, which should be the previous year's produce, is sown in June, 4 seers to the acre. In Coimbatore it is cultivated on dry lands, except black. It is often grown as a mixed crop with cotton, castor-oil, pulses, etc. The land is ploughed in April, during the heavy rains, after having been manured.
Mixed Cultivation.	In July–August it is again ploughed, and the seed, mixed with various pulses, is sown broadcast, with <i>dál</i> or beans in rows a few feet apart. After six weeks the crop is interploughed and occasionally weeded. In November–December it is reaped by cutting off the ears as they ripen. The pulses are gathered gradually up to February, when the <i>kambu</i> stalks, beans, etc., are all pulled up together, leaving the cotton and castor only.
Seasons.	Bur. a. —In 1905–6 the area was 74,802 acres, all in Upper Burma, and chiefly in Myingyan, 42,958 acres, and Magwe, 26,526 acres.
urma.	Diseases. —An interesting account of the disease known as <i>Sclerospora graminicola</i> is given by Butler in the <i>Memoirs of the Department of Agriculture, India</i> (1907, ii., No. 1). As Butler points out, however, it is not usually of sufficient intensity to attract much attention. [<i>Cf.</i> Maxwell-Lefroy, <i>Mem. Dept. Agri. Ind.</i> , 1908, ii., 9.]
Food.	FOOD AND FODDER. —The grain is used chiefly by the lower classes of Natives, and in many parts of India is their staple Food. The flour, made into cakes or bread with butter-milk, is considered more nutritious than rice. In Khandesh it is often eaten with butter and various condiments. The following is the analysis published by Leather (<i>Agri. Ledg.</i> , 1901, No. 10, 370; 1903, No. 7, 151, 154, 181):—moisture, 8·77 per cent.; oil, 5·33; albuminoids, 9·52; soluble carbohydrates 73·52; woody fibre, ·78; soluble mineral matter, 1·73; sand and silica, ·35; total nitrogen, 1·61; albuminoid nitrogen, 1·51.
Bread.	In the Panjáb, <i>bájra</i> is occasionally grown for FODDER and in unfavourable seasons may be given to cattle in the green condition, especially if the crop has proved a failure. The stalks, after the grain has ripened, are more or less utilised in all the provinces where available. In the Karnál district it is said that in some of the higher villages the stalks, called <i>dándar</i> , are even stacked and preserved until required, when they are chopped up and given to cattle along with green fodder. <i>Bájra</i> straw is much more generally employed as a cattle fodder in the Madras Presidency than in most other provinces. [<i>Cf.</i> Church, <i>Food-Grains of Ind.</i> , 1886, 56–9.]
Fodder.	

P FU Y (see ils, p. 820).

D. P., vi., pt. i., 157–80. Petroleu . P T L U ; Ball, in *Man. Econ. Geol. Ind.*, iii., 124–54; Fritz Noetling, *Occur. of Petrol. in Burma*, in *Mem. Geol. Surv. Ind.*, 1897, xxvii., pt. 2; Holland, *Rev. Min. Prod. Ind.*, in *Rec. Geol. Surv. Ind.*, 1905, xxxii.,

pt. 1, 69-77; 1906, xxxiii., pt. 1, 15; 1907, xxxvi., pt. 2, 77. The *mitti-ká-tél*, *kala salajit*, *minak tanah*, *manyenney*, *manti-tayilam*, *yé-ná*, etc. Petroleum, otherwise known as mineral or rock oil or naphtha, is essentially a mixture of hydrocarbons of the paraffin and olefine series. It occurs stored in loose-textured conglomerates and sandstones, in which its distribution is similar to that of water in porous strata, being retained by impervious beds of clay. It may exude through any accidental fissure at the surface of the earth and thus form natural oil-springs, but is chiefly obtained by boring through the impervious covering strata into the oil-sands below, from which the oil may be raised by pumping; or it sometimes "gushes" out by pressure of the associated gaseous hydrocarbons. As to its origin, various theories have been advanced, such as that it is derived from the action of water on strongly heated iron carbide contained in the interior of the earth: and that it has been formed by the decomposition of the remains of animal matter at a high temperature or in contact with saline deposits, and the subsequent resolution of the more permanent fatty constituents into hydrocarbons and free carbon dioxide. Ball remarked on this subject, "There can be little doubt that the formation of petroleum is intimately, though obscurely, connected with the presence of salt, otherwise it would be difficult to account for the simultaneous occurrence of petroleum and brine-springs, which have been observed in India, as well as in Pennsylvania and Virginia."

Source.

Origin.

Although much progress has been made in developing the petroleum resources of India, at the present day, according to Holland, these afford little more than $1\frac{1}{4}$ per cent. of the world's supply. The chief sources are the United States and Russia, which together produce about 90 per cent. [Cf. Redwood, *A Treatise on Petroleum*, 1906, for an account of the chief occurrences and a full bibliography.] The following figures show the huge increase in the Indian production within recent years:—1890, 4,132,287 gallons; 1895, 13,003,748 gallons; 1900, 37,729,211 gallons; 1904, 118,491,382 gallons; 1906, 140,553,122 gallons. The traffic of 1906 on 1905 represents an expansion of 22.6 per cent.—mainly in the new Singu field, of which it is believed a large portion is still held in reserve.

World's Supply.

Indian
Production.

OCCURRENCE.—According to Holland, petroleum in India is confined to the two systems of folded rocks at either extremity of the Himalaya—(1) the Iranian on the west, including the Panjáb and Baluchistan, and continued beyond British limits to Persia, and (2) the Arakan system on the east, including Assam and Burma, and continued to the oil-fields of Sumatra, Java and Borneo. In both areas the oil is associated with tertiary strata.

Indian Areas.

Panjáb and United Provinces.—The districts from which oil has been reported are Shahpur, Jhelum, Bannu, Kohát, Rawalpindi, Hazará and Kumaon. The output, however, is small, ranging between 1,000 to 2,000 gallons a year. In 1903 it amounted to 1,793 gallons, and in 1906 stood at 871 gallons.

aluchistan.—The early efforts made to develop the oil resources in different parts of Baluchistan have been described in the *Dictionary*. The most prominent of these are near Khotan in the Marri hills and Moghal Kot in the Shiráni country, where springs examined in 1891 were found to yield oil of a high quality. Holland says that the oil-spring in the neighbourhood of Moghal Kot affords a good illustration of the way in which a country, well endowed with the conditions necessary for the

Northern
India.

Moghal Kot.

production of petroleum, may lose its resources by destruction of the natural reservoirs. "The Moghal Kot oil-bearing beds form a very open anticlinal fold, whose axis pitches to E.N.E., and if the dome possessed the necessary plastic, impervious envelope, the oil rising up from below would have become concentrated in the porous beds which form the saddle, but for the fact that along this line the rocks are more easily eroded by surface water, and the anticline thus forms the gorge of a river by which the rocks have been opened to permit the waste of oil for an indefinite time" (Holland).

[*Cf. Holland, Min. Oil from Suliman Hills*; also Oldham, *Rept. on Oil Locality near Moghal Kot*, in *Rec. Geol. Surv. Ind.*, 1891, xxiv. pt. 2, 83-97; De La Touche, *Rept. on Oil Springs at Moghal Kot*, in *Rec. Geol. Surv. Ind.*, 1892, xxv., pt. 4, 171-80; also *Rept. Exper. Boring at Sukkur*, 1895, xxviii., pt. 2, 56-8; *Progress of Petrol. Operat. in Baluchistan*, Govt. *Publicat. Simla*, June 13, 1892.]

Eastern
India.

Makum.

Wells.

Yield.

Assa.—In 1865 the springs in the Assam oil-fields were visited by Medlicott, who stated that, though the discharge was small, they were the most promising he had seen. In 1867 a Calcutta firm obtained permission to prospect and struck a promising oil-spring at a depth of 118 feet near Makum, but nothing more was done till 1883, and very little development occurred in the following sixteen years. These oil-fields were first systematically reported on by Mallet (*Mem. Geol. Surv. Ind.*, 1876, xii., 356), and were again examined by Mr. R. A. Townsend, Superintendent Petroleum Works, Baluchistan. According to Mallet, the oil-springs may be classified for commercial or leasing purposes into the following districts—(1) those of the Tipam Hill, north of the Dihing; (2) those of the range between the Dihing and Disang; (3) those of the Makum coal-field, south of the Dihing between the Dirack and Tirap rivers; (4) those to the east of the Tirap. The chief locality is that of the Makum coal-field, the best wells being at Digboi. In 1899 the Assam Oil Company was formed with a nominal capital of £310,000 (*Holland, Rev. Min. Prod. Ind.*, l.c. 75). The result was that the output rose from 623,372 gallons in 1899 to 1,756,759 gallons in 1902; 2,585,920 gallons in 1904; and 2,733,110 gallons in 1905.

Holland observes that "the belt of tertiary rocks extending from the north-eastern corner of Assam for about 180 miles south and west shows frequent signs of oil, nearly always in association with coal and sometimes associated with brine-springs and gas-jets. The series of earth-folds in which this corner of Assam occurs stretches southwards to Cachar, where oil-springs are also known, through the little-known Lushai hills into Arakan, and in the same system of parallel folds occur the oil-fields of the Arakan coast on one side of the Yoma, and those of the Irrawaddy valley on the other." [*Cf. Repts. of Assam Oil Coy., Ltd.*, 1900-3.]

ur a

Irrawaddy
Valley.

ur a.—Holland furnishes the following brief account of the areas of Burma that are actually worked at the present day. "The most productive oil-fields of Burma are those on the eastern side of the Arakan Yoma, in the Irrawaddy valley, forming a belt stretching from the Magwe district, in which the well-known field of Yenangyaung occurs, through Myingyan, in which Singu occurs, across the Irrawaddy into Pakokku, where Yenangyat is situated. Oil is, however, known further south in Minbu, Thayetmyo and Prome, and further north in the Chindwin valley, but these areas have not so far been thoroughly prospected, and the great development which has recently taken place has been the direct outcome of work in the three fields, Yenangyaung, Yenangyat, and Singu."

INDIAN PRODUCTION

P T L U
Production

"Yenangyaung, the best known and most developed of the fields, still holds the lead as producer. The oil in this area has been worked by Native wells on both sides of the dome for well over one hundred years, and before 1886 the annual yield was generally over two million gallons, but soon after systematic drilling was introduced in the central Kodaung tract in 1887, the output gradually rose to over 10 million gallons in 1894, and last year, 1903, reached a record of 56,920,662 gallons." In 1904 the output of Yenangyaung was 73,428,960 gallons, and in 1905, 85,648,749 gallons.

"Yenangyat yielded very small supplies of petroleum before 1891, when drilling was started by the Burma Oil Company. The expansion was slow until 1894, when 324,086 gallons were produced, but rose rapidly to 6,036,088 gallons in 1898, to 22,665,518 in 1903." It has since, however, dropped to about 18½ million gallons a year.

"Singu has suddenly come into prominence. Petroleum was first struck by the Burma Oil Company in this area on October 30, 1901, and arrangements were then made to provide tanks for its reception. Production did not consequently begin till 1902, when only 174,880 gallons were turned out, with the opening of the new wells, but the output jumped up to 5,617,381 gallons in 1903; 23,677,450 gallons in 1904; and 37,541,177 gallons in 1905. The crude oil first obtained had a specific gravity of 0·8247 and flash-point under 40° F., in consequence of which primary stills were erected on the field to remove the light naphthas before transport to the Rangoon refineries."

"Besides the Upper Burma oil-fields, the islands off the Arakan coasts, noted for their mud volcanoes, have also been known for many years to contain oil deposits of uncertain value. The chief operations have been carried on in the Eastern Barongo Island near Akyab and on Ramri Island in the Kyaukphyu district. During the past six years the average output of the former area has been 42,926 gallons, whilst in Kyaukphyu the output in the same period has averaged about 100,000 gallons, with a distinct tendency to decline," but the output from these islands is now rapidly diminishing.

The total production of oil in Burma in 1905 amounted to 142,063,846 gallons. The output of the various oil-fields was as follows:—Akyab, 53,455 gallons; Kyaukphyu, 60,647; Yenangyaung, Magwe, 85,648,749; Singu, Myingyan, 37,541,177; Yenangyat, Pakokku, 18,759,818.

Properties and Uses.—For particulars regarding the introduction and expansion of the demand for kerosene oil for illuminating purposes in India, the reader is referred to the particulars given under *ils* (see p. 812). The following information on the composition and uses of petroleum is abstracted mainly from the account published by Mr. Edmond O'Neill (*Develop. of Petrol. Indust.*, 1901). Chemically considered, petroleum is a liquid of varying composition. The colour ranges from clear water, white through shades of yellow, amber, and brown to black. Its viscosity varies from great mobility to a thick tar-like mass, and its specific gravity from 0·771 to 1·020. The refractive index and coefficient of expansion are high and the specific heat is low, but both vary in oil from different places. Oils from the same locality usually resemble one another, but not always.

Crude Oil as
Fuel.

Gas.

Kerosene.

Benzene.

Paraffin.

Purification.

Recrystallisation.

Legisla-
tion.

Flashing-point.

Apparatus Used.

Crude petroleum is used to a very slight extent otherwise than as a fuel, a mixture for insecticides and for coarse lubrication. A quantity is also used in gas-making. For other purposes it must be refined, and this is effected by distillation. The crude oil is made up of a number of products of different boiling-points, some gaseous, some liquid, some solid. On boiling the oil and condensing the vapours, first the gaseous, then the liquid, and then the solid pass over, leaving a non-volatile residue. These distillates and the residue are themselves made up of a number of different bodies that may to a certain extent be separated. The most valuable of these is the illuminating oil, known also as KEROSENE, coal oil, burning naphtha and by various other names. The portions of the distillate boiling at lower temperatures than the illuminating oils are also of commercial value. They are known as gasolenes, rhigolenes, ligroines, benzenes, petroleum spirits, etc. Their principal use is as solvents for fats, oils, varnishes, paints, and as fuel for gas engines, gas machines, ice-making machines, and other purposes. The higher boiling portions of the distillate are employed chiefly as lubricants. Still higher boiling portions that condense to solids and semi-solids are known as vaselines and paraffins.

Simple distillation is not sufficient to prepare the above substances, so that they can be satisfactorily used. They must be purified. This usually consists in distilling, washing with acid (mostly sulphuric), alkali (usually soda or ammonia), and water. Sometimes the distillates are sprayed through air to remove malodorous constituents. Some of the oils are bleached either by the sun or by chemical reagents, or they may be filtered through charcoal or bone-black. In the case of solids, recrystallisation is ordinarily resorted to, i.e. the body, such as paraffin, is dissolved in some of the low-boiling constituents, usually naphtha, and the solution cooled in ice and salt. The paraffin thus crystallises out.

[*Anal. of Petrol.*, in *Rec. Geol. Surv. Ind.*, 1891, xxiv. pt. 4, 251; Engler, *Chem. Qual. of Petrol. from Burma*, 1894, xxvii., pt. 2, 49-54; Hurst, *Soap Making*, 1898, 56-7; Thorpe, *Dict. Appl. Chem.*, 1900, iii., 111-20.]

Tests and Legislative Measures.—The term "Flashing-point" is technically employed to designate the temperature at which any sample of petroleum or its products begins to give off sensible quantities of inflammable vapour. To prevent accidents it was enacted by the American Petroleum Act, and by the British Petroleum Act of 1871, that no petroleum oil should be used for burning in lamps which gave off inflammable vapours at any temperature below 100° F. (38° C.) when tested in an open cup described in the schedule of the Act. The increase in the consumption of the article, however, between 1871 and 1877 necessitated the adoption of a system of testing less liable to vary. The question was referred to the late Prof. Sir F. Abel, who proposed the use of a closed vessel to be heated in hot water, with a standard flashing-point of 73° F., equivalent to 100° on the open-cup system. This proposal was eventually adopted as the basis of the English Petroleum Act of 1879. The law under which petroleum is tested in India is Act XII. (1886), in which the testing apparatus prescribed is an improved form of Abel's. Several other modifications, based on the special conditions attendant on the application of the test in a warm climate, have also been incorporated in the schedule of the Act. As changes of pressure influence the flash-point, a table showing the corrections to be applied for variations in barometric pressure is also

appended. Dangerous petroleum is defined as petroleum having a flash-point below 76° F., but a consignment guaranteed uniform is not to be considered dangerous if it has an average flash-point of 73° and no sample flashes below 70° F.

Dangerous
Petroleum.

Revenue.—In 1888 an import duty of half an anna a gallon was levied by the Government of India on petroleum, and in 1899–90 the revenue obtained amounted to Rs. 1,62,392. In 1894–5 this tax was doubled, as part of the means adopted to reduce the large deficit which then existed. The revenue from petroleum in that year was Rs. 3,17,995. Since 1894 the tax has remained at 1 anna per gallon, and the revenue thus obtained during the five years 1900–6 amounted to the following figures:—1900–1, Rs. 49,29,432; 1901–2, Rs. 53,05,104; 1902–3, Rs. 53,79,857; 1903–4, Rs. 43,99,912; 1904–5, Rs. 45,88,289; 1905–6, Rs. 36,64,723 (= £244,314).

Revenue.

One Anna per
Gallon.

TRADE.—Internal.—The movements within India itself are instructive. Thus the total recorded EXPORTS of internal trade transactions by rail and river in 1904–5 amounted to 4,366,522 cwt.; in 1905–6, 4,458,544 cwt.; and in 1906–7, 6,194,699 cwt. Of that amount Bengal exported 2,592,587 cwt.; Bombay port, 1,531,394 cwt.; Madras ports, 983,133 cwt. The chief IMPORTING provinces were Eastern Bengal and Assam, 1,294,710 cwt.; Madras, 892,290 cwt.; United Provinces, 851,335 cwt.; Bombay, 678,944 cwt.; Calcutta, 642,135 cwt.; Central Provinces and Berar, 587,547 cwt. The total coastwise transactions may be represented by the following quotations:—IMPORTS, 1901–2, 17,187,223 gallons, valued at Rs. 70,97,587; in 1903–4, 40,469,364 gallons, valued at Rs. 1,62,72,273; and in 1906–7, 66,065,365 gallons, valued at Rs. 2,40,54,011. Of EXPORTS, Burma supplied in 1906–7, 58,572,648 gallons, and Bengal, 1,231,537 gallons. Of that supply Bengal took 33,074,834 gallons; Bombay, 9,226,720 gallons; Sind, 2,428,796 gallons; and Madras, 8,896,029 gallons. But in addition to Indian petroleum, foreign oil is carried along the coast. In 1901–2 this came to 6,069,534 gallons, and by 1906–7 had decreased to 2,304,032 gallons, the major portion being from Bombay to Madras, Kathiawar and Goa.

Trade—
Internal.

By Rail and
River.

By Sea
Coastwise.

The Trans-frontier export trade in petroleum shows in recent years a steady increase. In 1904–5 the figures were 160,559 cwt., valued at Rs. 10,65,506; 1905–6, 180,748 cwt., valued at Rs. 11,15,212; 1906–7, 178,533 cwt., valued at Rs. 11,81,921. The largest quantities go to Nepal, viz., in 1906–7, 100,938 cwt., while considerable quantities are also conveyed to the Shan States and Kashmir. The imports during the same period are unimportant, amounting in 1906–7 to only 66 cwt.

By Land Routes.

External (Foreign) Exports.—The foreign EXPORT trade in petroleum has sprung into eminence within the last two or three years. The following are the exports of kerosene and paraffin wax for the period 1900–7:—1900–1, 258,752 gallons kerosene, valued at Rs. 1,29,376, and 37,943 cwt. wax, valued at Rs. 7,94,551; 1901–2, 16 gallons kerosene, valued at Rs. 8, and 54,097 cwt. wax, valued at Rs. 9,45,443; 1902–3, 2,085 gallons kerosene, valued at Rs. 1,050, and 56,464 cwt. wax, valued at Rs. 10,43,149; 1903–4, 913,908 gallons kerosene, valued at Rs. 4,27,692, and 43,894 cwt. wax, valued at Rs. 8,13,128; 1904–5, 4,076,139 gallons kerosene, valued at Rs. 19,99,413, and 54,707 cwt. wax, valued at Rs. 11,13,777; 1905–6, 1,766,566 gallons kerosene, valued at Rs. 8,83,151, and 56,795 cwt. wax, valued at Rs. 11,58,394; and in 1906–7, 24,684 gallons kerosene, valued at Rs. 10,928, and 60,208 cwt. wax, valued at

External
Exports.

Exports of
Kerosene and
Paraffin.

Rs. 12,42,601. Exports of mineral oils, other than kerosene, amounted in 1904-5 to 164,253 gallons; 1905-6, 12,962 gallons; and 1906-7, 881,452 gallons. India also re-exports large quantities, amounting in 1904-5 to 2,097,472 gallons; 1905-6, 1,161,012 gallons; and in 1906-7, 486,676 gallons.

I ports.

R ia and the
United States.

I ports.—The IMPORTS of mineral oils are large and important. According to Holland, during the years 1897-1903 they averaged nearly 85½ million gallons, valued at £2,314,801. Of the two great producing countries, Russia and the United States, which during the years in question supplied between them about 93·5 per cent. of the imported foreign oil, Russia has been gradually increasing its predominance over the States. "In 1897-8 Russia contributed 58·1 per cent. of the imports and the States 29·7, but in 1901-2 the former had secured 85·5 and the latter only 9·5 per cent. of the Indian custom, though a slight reversal occurred in 1902-3" (Holland). In the *Imperial Gazetteer of India* (iii., 139) later particulars are given. Of the imports, it is said of the foreign oil that "about 75 per cent., amounting to 64 million gallons a year, comes from Russia, and 19 per cent. from the United States, while large quantities are now being obtained from the productive fields in the Dutch East Indies."

Recent Returns.

In the *Review of the Trade of India* (1905-6, 15-6) the total value of all mineral oils imported in that year into India is stated to have been Rs. 222·9 lakhs, or 32 per cent. less than in 1904-5. Of this total, Rs. 178·3 lakhs, or just 80 per cent., had reference to kerosene. During the years 1900-6 the imports of kerosene (*omitting last three figures*) are quoted as follows:—1900-1, 72,602 gallons, valued at Rs. 3,10,34; 1901-2, 91,467 gallons, valued at Rs. 3,51,57; 1902-3, 81,451 gallons, valued at Rs. 3,14,61; 1903-4, 71,559 gallons, valued at Rs. 3,07,58; 1904-5, 76,190 gallons, valued at Rs. 2,97,56; 1905-6, 50,949 gallons, valued at Rs. 1,78,32. During the same period, it is interesting to note that the exports from Burma (*omitting last three figures*) rose from 8,269 gallons, valued at Rs. 33,53, in 1900-1 to 47,160 gallons, valued at Rs. 1,62,34, in 1905-6, and that while in 1905-6 the imports of foreign kerosene declined by 33 per cent. in quantity and 40 per cent. in value on the imports of the previous year, the exports from Burma to India are stated to have increased by 10 per cent. in both respects.

Foreign and
Local Supplies.

Analysing the figures of supply, we learn that Russia gave to India (*omitting last three figures*) in 1901-2, 84,478 gallons, and in 1905-6, 7,617 gallons; the United States, 5,768 and 22,332; the Straits Settlements, 1,023 and 10,391; and Sumatra, *nil* and 5,401 gallons. As a parallel to these records, it may be here added that Burma supplied India in 1901-2 with 13,463 gallons, and in 1905-6 with 47,160 gallons. It is also stated that "case oil" is giving place to "bulk oil" importation, and that "more than half of the above decline in total imports is to be traced to the falling off of 11½ million gallons in arrivals of case oil from Russia alone, this being due to the destruction and anarchy that prevailed in the Russian oil region."

Prices.

Prices.—The following average prices in Calcutta, during 1905-6, of various classes of kerosene are quoted in the *Review* (l.c. 16):—American, Chester, per case, Rs. 4-2-9; Russian, Rising Sun, per case, Rs. 3-10-6; Anchor, per case, Rs. 3-6-8; Ram, per case, 3-9-7; Burma, Victoria, per 2 tins, Rs. 2-11-5; Gold Mohar, per 2 tins, Rs. 2-14-6; Borneo, Cobra, per 2 tins, Rs. 2-11-9; Sumatra, Silver Light, per 2 tins, Rs. 2-11-9.

ACONITE-LEAVED KIDNEY BEAN

PHA LU
ACONITIF LIU

Sumatra, Silver Light, per case, Rs. 4-13-8. The prices of American Chester Oil, the standard illuminant, are shown to have been very steady for the last ten years. In 1896-7 the average price per case was Rs. 4-3-3, and in 1905-6, Rs. 4-2-9.

Aconite-
leaved.

Generally cultivated in the plains as a hot-weather crop (June-July) and reaped in autumn (*khariif*, October-November), and specially suited to dry, light sandy soils and for green-manuring (Watt, *Pests and Blights of the Tea Plant*, 1898, 175, 177). In some localities it is an important crop, as in the United Provinces, where in 1904-5, together with *urd (P. Mungo, Linn.)*, *mung (P. radiatus, Linn.)*, and *lobia (Vigna Catjang)*, it occupied an area of 1,062,783 acres; and in Bombay (including Sind), where it alone occupied in 1905-6, 299,701 acres. Of the United Provinces, Duthie and Fuller state that it grows on the worst land that can be made to bear a crop. It is sometimes sown alone, but more often in millet fields, especially of the spiked or bulrush millet (*bájra*). Its cultivation is very haphazard. Two or three ploughings are held sufficient, and the seed is sown broadcast at the rate of 4 seers to the acre. The highest outturn which could be taken as an average is 8 maunds to the acre with rather less than double that amount of fodder. Of Bombay, Mollison (*Textbook Ind. Agri.*, 1901, iii., 85-6) states that this pulse is fourth in importance, and is grown to a considerable extent in all districts except the Konkan. It is rarely sown alone, and is a common subordinate crop with *bájra*. The best outturn is obtained on the deep alluvium sands or sandy loams of Ahmadabad and Kaira. Heavy rain is harmful, and it is most successfully grown with a well-distributed rainfall of about 30 inches. It ripens after the *bájra* and is reaped in November-December. A fair yield in an average season may be 120 lb. pulse per acre from a seed-rate of 1½ lb. with the value of the pulse at 40 to 45 lb. per rupee.

Mixed
Cultivation.

The beans are used to a considerable extent in certain parts of India, Vegetable.

especially in Bombay, as a VEGETABLE. The pulse is split and eaten as *dāl*, also cooked in various ways. It is considered a useful MEDICINAL diet in cases of flatulence, and as a food in fever. The whole plant is a valuable FODDER and is frequently grown, either alone or mixed with some millet, for this purpose exclusively. [Cf. Church, *Food-Grains of Ind.*, 1886, 152; Leather, *Agri. Ledg.*, 1903, No. 7, 152, 156, 181.]

D.E.P.,
vi., pt. i.,
1 6-7.
Lima.

P. lu tu, Linn.; *Kew Mus. Guide*, 1907, 68. Lima or Duffin Bean, *kursumbulle-pullie*, *bunbur-butti*, *tik-bit-zim*, *kerow-simbi*, *kataridabooa mah*, *udadyaweli*, *peggi*, etc. A tall biennial, with long scimitar-shaped pods and large seeds of variable colour. According to De Candolle, this is a native of Brazil. In India it is very generally cultivated, especially in Assam, Burma, Bengal, the United Provinces, the Panjáb, etc.

Seasons. According to Firminger (*Man. Gard. Ind.* (ed. Cameron), 180), the seed should be sown in the plains during October (or just when the rains are over) and in rows about 4 inches apart; on the hills the sowing season is from March to June. The ripe seeds of the best kinds are pure ivory-white, and, when cooked in a similar way to haricot or broad beans, are used as a VEGETABLE and said to have the flavour of roasted chestnuts. Duthie says the young pods are sliced and cooked like French beans.

Poisonous Property. Interest has recently been aroused in this bean owing to the poisonous properties which the species sometimes exhibits. A report was issued by Dunstan on its chemical composition (*Proc. Roy. Soc.*, 1903, 72, 285; also *Agri. Ledg.*, 1905, No. 2). The first specimens examined came from Mauritius, where the plant is raised in a practically wild state and used as a green manure. Chemical examination showed the presence of a cyanogenetic glucoside (*phaseolumatin*) and an enzyme. When these two were brought into intimate contact, the glucoside was decomposed by the enzyme, yielding, amongst other substances, about 0.04 to 0.09 per cent. by weight of prussic acid, the largest quantity being found in seeds with dark, purple-coloured testa, and the smallest in seeds with almost white testa. In partially or wholly cultivated forms, the testa is either pink with a few purplish spots, pale cream-coloured or even white. Dunstan states that these are undoubtedly less poisonous than the almost wild type grown in Mauritius. While the Mauritius beans were being investigated there were imported into England from India quantities of beans described as Rangoon, Burma or Paigya beans, which were intended to be used in preparing food-stuffs for cattle. Plants were grown from some of them, and identified as *P. lunatus*.

P. c Acid. [Cf. *Bull. Imp. Inst.*, 1903, i., 16, 115]. Subsequently authentic samples of the beans were procured from Pakokku district, Burma, and these were found to contain 0.009 per cent. of prussic acid, a quantity quite sufficient to render them undesirable for consumption, at any rate in the raw state. Dunstan concludes by advising the cultivators of this particular bean to grow perfectly white forms rather than coloured varieties. Leather (*Agri. Journ. Ind.*, 1906, i., pt. iii., 224), in a paper on *Cyanogenesis in Plants*, alludes to the poisonous property. "I have obtained prussic acid," he says, "from Rangoon beans (*Phaseolus lunatus*) and *vál* (*Dolichos lablab*) by simply allowing the crushed seeds to remain in cold water for a few hours" (see p. 767). More recently, Dunstan and Henry (*Journ. Board Agri.*, 1908, xiv., 722-31) have given additional particulars and reviewed the results obtained by other investigators. They then conclude that "it is undesirable that any further definite advice should be given to discontinue the use of Rangoon beans, since in spite of the fact that both the red and white varieties have now been shown to yield prussic acid, there is at present no evidence that this is formed in quantity sufficient to be injurious, and although these beans have been used as a feeding stuff now for some years, no poisoning cases have been traced to them so far as is known. At the same time, since the beans yield prussic acid in varying quantity, it is clearly not permissible to recommend them for use as a feeding material. All that can fairly be done at the moment is to place the facts on record." [Cf. Church, *Food-Grains of Ind.*, 1886, 155.]

HIGHLY PRIZED PULSE

A LU
U
Cultivation

Crops, 1882, i., 39-40, t. x. The *urud* (or *urd*), *dord*, *tircorai-kalai*, *másh-kulái*, *ramra*, *udid*, *adad*, *patchay-pyre*, *minu-mulu*, *hasaru*, etc. There has been some confusion regarding the nomenclature of *P. Mungo* and the species which follows—*P. radiatus*,—due chiefly to Roxburgh having transposed the original Linnean names. *P. Mungo*, *Linn.*, is the present plant, *udid* or *urd*; while *P. radiatus*, *Linn.*, is the plant known in the vernacular as *mung*. There are two varieties of *udid*, one with large black seeds, the other with smaller greenish seeds, and these correspond very possibly with *P. Mungo* proper and the variety *Roxburghii*.

Varities.

Area.—*Urd* is the most highly prized of the pulses of this genus, and is largely cultivated in India, sometimes even in green manuring (see p. 225). Unfortunately the crop area is not uniformly and continuously recorded, so that only isolated quotations can be cited. In Bombay (including Sind) it occupied in 1905-6, 223,281 acres, but it would appear that either the wrong scientific names have been used in the official publications of Bombay (and in Mollison's *Textbook Ind. Agri.*) for this and the next pulse, or that the names *mag*, *mung* and *udid* have the opposite significations in Bombay to those prevalent in the rest of India. In the Panjáb in 1904-5 *mung* and *mash* together occupied 443,307 acres, and in 1906-7, 563,364 acres.

Area.

According to Duthie and Fuller, *udid* is grown commonly as a subordinate crop with millet or cotton, but more often by itself. Sowing takes place at the commencement of the rains, and the crop ripens, one variety in August and September, another in October and November. When grown alone it is sown broadcast at the rate of 4 to 6 seers per acre. It prefers the heavier classes of soil, and is thus unlike *mung*, which prefers lighter soil. In this respect, it will be seen, Mollison holds a slightly different opinion, since he believes that both beans prefer heavy soils. Its average outturn when grown alone is about 5 maunds grain per acre with three times this weight of straw. In Bombay, Mollison states that *udid* is grown generally subordinate to *juár* (*Sorghum vulgare*) or other cereals. It is a very important crop in the black soils of Khandesh, and is grown fairly extensively in Násik, Satara, Belgaum, Thána, and Ahmadabad. Of the total area during 1905-6, Khandesh had 106,870; Satara 33,673; Nasik 22,200; and Belgaum 14,689 acres. The total *rabí* crop came to 2,809 acres, of which 1,482 acres were in Kanara and 731 acres in Kolaba. It is raised mostly as a rain crop, subordinate to *juár*, but to a small extent alone in the *kharij* season, and over a considerable area in the *rabí*, chiefly as a second crop after rice.

Soils.

Yield.

Two Crops.

Uses.—The green pods are eaten as a vegetable and the ripe grain is the most esteemed of all pulses in India. It is boiled and eaten whole or after being split, in the form of *dál*. Parched and ground to flour it is made into balls with spice, or is eaten in the form of a sort of porridge or baked into bread—it is the chief constituent of the wafer biscuit known in Bombay as *pápad*. In the Panjáb it is used in the form of two preparations known as *bari* and *sepa*. Both are prepared by soaking the seed for a couple of days in slightly warm water, then crushing to a pulp, drying and mixing with *ghi* or buttermilk. Both the grain and the straw are valuable as horse and cattle food. MEDICINALLY this pulse is highly valued by the Hindus.

Mung.

P. r di tu, *Linn.*, *Sp. Pl.*, 1753, 725; Prain, in *Journ. As. Soc. Beng.*, 1898, lxvi., 422; *P. Mungo*, *Fl. Br. Ind.*, ii., 203 (in part); Duthie and Fuller, *l.c.* 37-8, t. ix. Green Gram, *mung*, *mag*, *pessara*, *kheriya*, *bulat*, *ghora muga*, *chhimi*, *pucha-payarú*, *wúthúlú*, etc. This pulse is a native of India and is met with both wild and cultivated throughout the plains, ascending to 6,000 feet in the outer ranges of the North-West Himalaya. There are three varieties, characterised by having green, yellow and black seeds. The confusion in nomenclature has already been explained under *P. Mungo*.

Area.

Area.—*Mung* is cultivated all over the Peninsula, though no estimate can be given of the total production. In Bombay, where it is returned separately (*Season and Crop Reports*), it is the fifth pulse in value, and occupied in 1905-6, 189,942 acres, and in Sind 32,690 acres. The most important centres are Dhárwár, Ahmadnagar, Khandesh and Bijapur. In Berar it would appear there were in 1904-5, 29,306 acres under it. The method of cultivation is essentially the same as for *urd*. Duthie and Fuller state that it is almost invariably a subordinate crop in fields of millet or cotton. It is, therefore, a *kharif* crop, sown at the commencement of the rains and reaped in October. Cultivation is the same as for cotton or millet. If sown alone, the seed-rate is about 12 seers to the acre. It is reaped about a fortnight before the millet crop, and threshed out by bullocks in the usual way.

Cultivation.

Subordinate
Crop.

Kharif Crop.

Rabi Crop.

Soils.

Pure Crop.

Its chief cultivation is the *kharif*, but in Dhárwár, Kolába and Kanara it is grown in the *rabi* season as a second crop after rice. It is then sown alone, subordinate to *judr* and other cereals. It does best on good, deep soil of fairly dense consistency, and with a well-distributed rainfall of 30 to 35 inches. When grown after rice in the *rabi* season, cultivation is the same as for *vál* (*Dolichos Lablab*), though the seed-rate is rather less (15 to 20 lb. per acre) and the preparatory tillage more careful. In the Deccan this pulse is sometimes sown alone in the *kharif* season as a catch crop before sugar-cane and other irrigated crops, which are planted in the *rabi* season (Mollison). The preparations made from *mung* are the same as those described for *urd*.

Date.
Habitat.

P. tylifer, *Linn.* The Edible Date; tree = *kha-júr*, *kasser*, *mach*, *karmah*, *pind chirdi*, *tár*, *péríta*, *swonpalwon*, etc.; fruit = *khúrma*, *chúhára*, *kukyán*, *pind*, *chirwi*, *jarikha*, *tamara*, *périch-chankay*, *somblón-zí*, etc.; *sindhi*, *seindi*, *sendri* are names for this tree that denote its origin from Sind. A tall tree, often 100 to 120 feet, producing, when young, offshoots or "suckers" at the base of the stem. According to De Candolle, it has existed from prehistoric times in the warm-dry zone which extends from Senegal to the Indus basin, principally between the parallels 15° and 20°.

CULTIVATION.—In India it is cultivated and self-sown in Sind and the Southern Panjáb, particularly near Multan, Muzaffargarh, the Sind Sagar Doab, and in the Trans-Indus territory. Near Dera Gházi Khán the trees are numerous, on a strip of country 10 to 12 miles long from north to south. A few are planted in the Eastern Panjáb, at Saharanpur, in the Ganges Doab, and in Bandelkhand. It is also grown in the Deccan and Gujarat. In recent years, through Government agency, plantations have been started in various places, *e.g.* in Sind. The chief difficulty in cultivating the tree is to secure the exact climatic conditions necessary for success. [*Cf. Sly, Exper. in Cult. of Dates, in Agri. Journ. Ind., 1906, i., pt. iii., 256-7.*]

Climate.—*Cli etc.*—Fletcher (*Agri. Ledg., 1906, No. 1*) gives a full account of the conditions under which successful cultivation is carried on in other countries. The relative low humidity and rainfall in typical date-growing regions is a marked feature. Rain at the time of flowering spoils the pollen, and during the ripening season causes fermentation of the fruit. The former, in all regions of successful production, is March to May, and the latter, August to November. Where the best dates are produced, more than half the total yearly rainfall occurs between November and March, thus before flowering commences. On an average, rainfall during the flowering and fruiting season should not exceed 5 inches.

In addition to this amount of rainfall, irrigation is absolutely essential, for if there be sufficient rainfall to dispense with irrigation, it will be too great to allow the flowers to pollinate and the fruit to set fully and ripen well. The requirements as to temperature are peculiar. In a dormant condition, it can withstand temperature as low as 20° F., but an extremely high temperature is necessary to enable it to ripen its fruit. Neither flowers nor fruits are formed unless the mean temperature rises above 64·5° F., and for the best and latest varieties (*e.g.* the Deglet Noor, Ayata, Algeria) the mean temperature for the fruiting season (May to October) should be above 84° F., and for one month at least above 94° F.

Soils.—The physical character of the soil, sand, loam or heavy clay appears to have little influence on growth and productivity, except that perhaps on light loam and sandy soils it comes to maturity and flowers and fruits earlier than on heavy soils. It is also peculiar in its indifference to the quantity of alkali in the soil. Investigations on the soil of Algerian palm-bearing tracts have shown that though it can grow in soils with 3 to 4 per cent. their weight of alkali, it does not fruit unless the roots reach a stratum where the alkali is below 1 per cent., and does not yield abundantly unless there are layers with less than 0·6 per cent. [*Cf. Swingle, Date Palm and Its Util. in S.W. States, Bureau Pl. Indust., U.S. Dept. Agri. Bull., 1904, No. 53.*] The alkali in question consists of chlorides and sulphates of sodium and magnesium.

Propagation.—Propagation may take place by seeds or offshoots. The latter method is the best, for if seeds are sown, half the seedlings turn out males, and, moreover, female seedlings seldom produce fruit equal to that of the stock. The offshoots are borne at the base of the stem of trees from 6 to 16 years old. These are removed from the parent when from 3 to 6 years old. The large leaves are cut away, leaving only the rootless stump of the offshoot, with its bud protected by leaf-stalk and young leaves. For India, April to September is probably the best time for removal of the suckers. They should be planted out in rows 25 feet apart

Season

	with similar intervals between the rows. Holes 3 feet deep and broad are made. Half of the excavated earth is mixed with its own volume of farm-yard manure, with 4 to 5 lb. of oil-cake, and filled in, the offshoot being set in the centre of the hole. Care should be taken not to cover the central bud and young leaves with earth. These should be retained a few inches above the level of the ground, and a circular trench, a foot in width, dug round for irrigation. Transplanted shoots should be watered every day the first month, twice a week the second month, and then every month for a year. For the first year, also, they should be protected from November to March by wrapping them in straw or matting.
Manure.	
Bud.	
Watering.	Watering. —After planting out the offshoot, its chief requirements are irrigation and pollination. No general rule can be given with regard to the amount of water required. This depends on local conditions; and further, the palm needs more water during certain seasons of the year than others. Generally, at the time of flowering (February–March) little or no water should be given; from May till the fruit ripens (September) water should be given liberally.
Seasons.	
Maturity.	Maturity. —The age at which palms commence to flower varies with the character of climate and soil, and the amount of water given. Eight years from the date of sowing may be stated as the age at which appreciable quantities of fruit begin to be produced. The male inflorescence consists of a stout stalk with a large number of slender branches to which the flowers are attached, the whole enclosed in a sheath, which is at first closed but later splits open. The inflorescence is cut from the tree generally immediately before but sometimes after the splitting of the sheath. One or two of the slender branches bear sufficient pollen for a whole female inflorescence; and as a male inflorescence bears over 100 branches, one suffices to pollinate 50 or 100 female inflorescences, according as one or two branches are used for each. The female inflorescences are also borne within sheaths, at first closed, later open. When they open, one or two branches of the male inflorescence are inserted among its branches. About three months after pollination, two of the three fruits produced by each fertilised flower fall off, leaving only one to ripen. At this time also (the beginning of June) some of the clusters of fruit should be removed from the tree to increase the supply of food to the remainder. About 10 to 15 clusters are usually allowed to remain. The period of ripening varies from June to October, according to variety and locality.
Pollination.	
Fruiting Season.	
Uses.	USES. —The tree yields a GUM (<i>hukm chīl</i>), used MEDICINALLY in the Panjab. In that province, mats, fans, baskets and ropes are made from the leaves, known as <i>bhūtrā</i> , <i>pattra</i> , <i>khūshab</i> . Woodrow (<i>Notes on Journ. from Poona to Nagor</i> in <i>Rec. Bot. Surv. Ind.</i> , i., 94) states that a species of <i>Phoenix</i> (identified <i>P. robusta</i> , Hook., f.) grows on the Western Ghats, Poona, known locally as <i>shik</i> and is the source of the so-called date-matting made in the district. The petioles (<i>chhari</i>) make excellent light walking-sticks, and split up they furnish material for crates and baskets. The fibrous network which forms the sheathing of the petioles, called <i>kabāl</i> , <i>khajūr ka bokla</i> or <i>khajūr mūnj</i> , is used for packing for oxen, and the fibre separated from it for cordage. In the Panjab the buds of fruit stalks, <i>buhārā</i> , is made into brooms.
Medicinal Gum.	
Mats.	
Walking-sticks.	
Tara-perfume.	From the fresh spathes (called <i>tara</i>) is obtained by distillation <i>tara-water</i> , strong but agreeable perfume, which is highly valued by Arabs and Persians and does not seem to be prepared in India. The date forms a large part of the food supply of the countries where it grows plentifully. Even in the Panjab and it is largely utilised. In Multan the hard and unripe date is called <i>gand</i> when it turns yellow, <i>dokā</i> ; when one side becomes soft, <i>dang</i> ; when quite

P IX
YLV T I
Trade

pind. *Pind* dates may be ripened on the tree, *van di pind*, or ripened after gathering, *pind kint*. Dates which have shrivelled on the tree are known as *kuk* or *kukan*. In Sind the fruit, when ripe, is designated *khurma*, and *chuwara* when plucked before ripe. In Muzaffargarh the most esteemed kind is called *chirni*. This is split down the middle and dried in the sun. The second best is called *pind*, and is eaten as it comes from the tree. The least esteemed, *būgri*, is boiled in oil and water. The terminal bunch or heart of young leaves (*gāchi*) is preserved when a tree is cut down, and eaten as a vegetable and made into curry. Like *P. sylvestris*, this species also yields a saccharine juice, from which SUGAR and a fermented drink may be prepared; but it is comparatively little used for this purpose, as when of good quality it is too valuable to be subjected to that treatment. The hard kernels of the fruit are ground into FOOD for camels, goats, sheep and horses. The green date, *khamāl*, is also given to sheep and cattle. The roasted kernels have been used as a substitute for coffee. The wood is light and fairly durable, and is used in Multan and Sind as beams for supporting roofs in Native architecture, and also for water-channels, bridges and other purposes.

TRADE.—Exports.—The exports of Indian dates are not as yet important; they have averaged about 130 cwt., valued at Rs. 1,215, during the four years ending 1904-5, but in 1905-6 were only 34 cwt., valued at Rs. 364, and in 1906-7, 14 cwt., valued at Rs. 254. The re-exports, during the same period, were as follows:—1900-1, 34,444 cwt., valued at Rs. 1,69,263; 1901-2, 27,632 cwt., valued at Rs. 1,41,939; 1902-3, 47,041 cwt., valued at Rs. 2,18,455; 1903-4, 25,330 cwt., valued at Rs. 1,27,277; 1904-5, 22,260 cwt., valued at Rs. 1,24,684; 1905-6, 23,542 cwt., valued at Rs. 1,31,373, and in 1906-7, 27,945 cwt., valued at Rs. 1,69,639.

Trade.

Exports.

I ports.—The foreign supplies, on the other hand, are large and important; in 1900-1 they came to 871,272 cwt., valued at Rs. 41,94,972; 1901-2, 901,006 cwt., valued at Rs. 42,11,091; 1902-3, 663,390 cwt., valued at Rs. 31,43,967; 1903-4, 725,003 cwt., valued at Rs. 36,27,590; 1904-5, 812,284 cwt., valued at Rs. 40,96,034; 1905-6, 867,229 cwt., valued at Rs. 44,87,709; and in 1906-7, 814,781 cwt., valued at Rs. 48,37,461. The largest quantities come usually from Turkey-in-Asia, viz. 479,200 cwt. in 1906-7; Arabia, 238,101 cwt.; and Persia, 73,863 cwt., and are received chiefly by Bombay and Sind, which took as their shares 562,335 cwt. and 205,571 cwt. respectively.

vi., pt. i.,
20-1.
Wild Date.

Like the former, this species yields a GUM, and the leaves, petioles, flowering spathes, etc., are variously utilised for purposes similar to those indicated above. The reader will find these detailed in the article **askets and Wicker Work** (pp. 115, 188). The tree flowers at the beginning of

Gum.

Baskets and
Mats.

Aonlá

the hot weather and produces an inferior yellowish or reddish fruit, which is eaten by the poorer classes.

Sugar.

In many localities, however, especially in Jessore and other districts of Bengal, this species is of considerable importance as a source of food-supply, owing to the extensive use of its sap in making SUGAR. The Government of India (Resolution dated March 20, 1889) mention that it had been ascertained after a careful inquiry that there were 168,262 acres under cultivation of this palm connected with the sugar supply. A full account of the process of tapping the trees and of the manufacture of sugar from the crude sap is given in the *Report on the District of Jessore*, 1874, by the late Sir James Westland. Tapping ordinarily commences in November, and the largest supply of juice is obtained during December and January. An average amount of 5 seers of juice per night may be got from a good tree. The juice is boiled down into a dark brown, half viscid mass, called *gúr*. About 7 to 10 seers of juice are required to produce 1 seer of *gúr*. The tapping season lasts 4½ months or 67 nights. Thus at 5 seers a night, 335 seers of juice are obtained, or about 40 seers or 1 maund of *gúr* per tree, worth, say, Rs. 2 to Rs. 2-4a. After the juice is boiled down into *gúr*, it is then sold to the sugar-refiners and by them is manufactured in various ways into different grades of sugar. The best known is termed *dhulua*, a soft, moist, powdery sugar, used largely in the manufacture of Native sweetmeats. A purer, granular and more expensive sugar than *dhulua* is called *pucka*. The waste molasses, collected during the preparation of sugar, is called *chitiya gur*; this is boiled down into a black, sticky treacle, which is largely utilised for mixing with the tobacco for the Native *hookah* and also for making cheap Native sweets. A small proportion of the juice, instead of being used in the above way, is consumed as a drink, either unfermented or fermented, under the name of *tari*, or is converted into vinegar (see *pirits*, p. 1046; *Vinegar*, p. 1109).

Vinegar.

In recent years an interesting endeavour has been made to promote the manufacture of palm-sugar in the Central Provinces. A company has been formed under the name of the Khandwa Sugar Manufacturing Company. Full details regarding this will be found in a pamphlet (pub. 1901) by Mr. Haridas Chatterji, Managing Director, and in a report on the result of the first year's operations. [Cf. Kanjilal, *Date Sugar Indust. of Beng.*, in *Ind. For.*, 1892, xviii., 451-7; *Pharmacog. Ind.*, 1893, iii., 520; *Rept. Land Rec. and Agri. Gum.

Dye and Tan.

It yields a GUM of which little is known. Fruit, bark and leaves are employed in DYEING and TANNING. Hooper (*Agri. Ledg.*, 1902, No. 1, 52-3) states that the dried pulpy portion of the immature fruit affords as much as 35 per cent. tannic acid, but in a ripe state only traces are found. The leaves are regarded by the Bengal *chamars* as one of the best tans, and are said by

Hummel to contain 18 per cent. tannic acid. The bark is employed for tanning in Travancore. An extract prepared at Dehra Dun from bark supplied from the Central Provinces yielded 28.2 per cent. of tannin. As a dye, the fruit gives a blackish grey, if used alone, but is generally mixed with salts of iron or the barks of others trees to produce a black. Bark and leaves give the same colours as the fruit. Duncan (*Monog. Dyes and Dyeing in Assam*, 1896, 40-1) mentions that in the Jorhat Division of the Sibsagar district, the barks of three trees, viz. *Terminalia Chebula*, *Eugenia Jambolana*, *Psidium Guyava*, are used along with that of *Phyllanthus* to produce a black colour.

The fresh juice is used with that of the other myrobalans as a cooling, refrigerant sherbet and as a flavouring ingredient in vinegar (see p. 1109); while the fresh ripe fruits are largely employed as astringent and laxative medicines. The fruit is also eaten by Natives and made into preserves. An interesting use of the fruit pulp in the manufacture of pottery has been published by Hooper (*Journ. As. Soc. Beng.*, 1906, n.s., ii., 65). This was originally made known in 1896 by Mr. James Martin in a letter from Raipur, in the Central Provinces. The fruit is boiled, Martin says, in water till it becomes soft, then pounded; and after the stones are removed, the pulp is beaten and worked up into a dark-brown sticky mass. The manufacturer now takes an earthen vessel and plasters it over with a thick layer of the pulp. It is then set aside to dry, and when quite hard, the pot inside is broken and the pieces removed. These curious pots are sold in the district at from 4 to 8 annas each, and are much sought after, as they are durable and ornamented by coloured seeds (*ratí*) sunk in the fabric in elaboration of a pattern. I may add that publication of this curious discovery was delayed pending the investigation of its possible adaptation as a waterproofing material or for other purposes which it seemed likely to fulfil. According to Gamble, the Wood makes good poles and is useful for agricultural implements, building and furniture. It is durable under water, and can be used for well-work. [*Cf. Baber, Memoirs* (Leyden and Erskine, transl.), 326; Bontius, *Hist. Nat. et Med. Ind. Or.*, in Piso, *Ind. Utri. re Nat. et Med.*, 1629, 109-10; Basu, *Agri. P. *iruri*, Linn.; *jarámlá*, *bhúin-án-valáh*, *sada-hazurmaní*, *niruri*, *kizhkáy-nelli*, *néla-usirika*, *mi-ziphiyu*, etc. A small herb found throughout the hotter parts of India from the Panjáb eastwards to Assam, and south to Travancore, Malacca and Ceylon, ascending the hills to 3,000 feet. The whole plant is considered a useful diuretic, and is much employed in Native medicine. [*Cf. Pharmacog. Ind.*, iii., 265.]

. *reticulatus*, Poir.; *panjoli*, *mákhí*, *búin-owla*, *kabonan*, *kamohi*, *pavana*, *datwan*, *pillánji*, *nalla-purugudu*, etc. A large, often scandent shrub, common throughout tropical India, Burma and Ceylon, especially on low, moist ground. Leaves, bark and juice are all used in Native medicine, while the root is said to be employed in Madras to produce a red dye. [*Cf. Pharmacog. Ind.*, iii., 264-5.]

PIMPIN LLA ANI UM, Linn.; **UMBELLIFERÆ**. The Anise, *saurif*, *saónf*, *anisún*, *mukhúri*, *ervados*, *sewa*, *burri-shep*, *sombú*, *kuppi*, *dodda-jírage*, *jeramanis*, *sa-mung-sa-ba*, etc. An annual herb, native of Egypt, Crete, Cyprus and many islands of the Greek Archipelago; introduced from Persia into Northern India, where it is cultivated by the Muhammadans.

D. P.,
vi., pt. i.,
3.
Anise.

An odorous principle is obtained by distilling the fruit, the product being the "oil of aniseed" of commerce. *Arak badián*, or water of anise, is a favourite perfume in India. Anise as a medicine and spice is mentioned in many of the early classical writings. The Indian trade in it is not large, the exports in 1904-5 having amounted to 1,041 cwt., valued at Rs. 11,152, and in 1906-7 to 990 cwt., valued at Rs. 11,862. This ordinarily goes chiefly to the Straits Settlements and Ceylon, but in 1905-6 the United Kingdom took 1,513 cwt. The European market is supplied chiefly by Russia, Germany, Scandinavia, etc. For a full account of the history of the oil and of its properties, the reader should consult

Oil of Aniseed.

Markets.

Gildemeister and Hoffmann, *Volatile Oils*, 1900, 558-63. [Cf. Tavernier, *Travels*, 1676 (ed. Ball), ii., 20; Taleef Shereef (Playfair, transl.), 101; Banerjee, *Agri. Cuttack*, 1893, 104-5; Thorpe, *Dict. Appl. Chem.*, 1898, i., 173; Schimmel & Co., *Semi-Ann. Rept.*, 1905, 11-2; April-May, 1906, 70.]

PINU, Linn.; *Fl. Br. Ind.*, v., 651-3; Gamble, *Man. Ind. Timbs.*, 1902, 703-10; Maxwell T. Masters, in *Journ. Linn. Soc.*, 1901-4, xxxv., 560-659; CONIFERÆ. A genus of coniferous trees of great economic value. Five species are indigenous in India.

Blue Pine. . *excelsa*, Wall. The Indian Blue or Five-leaved Pine. The *chila*, *kail*, *lim*, *tongschi*, *lamshing*, *raisalla*, *byans*, *yári*, *kaiar*, *tser*, *biár*, *keitri*, *partal*, *sam*, *limanza*, etc. A large evergreen tree of the temperate Himalaya at 6,000 to 12,500 feet, extending westward to Kafirstan and Afghanistan; eastward, except for gaps in Central and North-West Kumaon and Sikkim, to Bhutan (Gamble).

Turpentine and Tar. The wood is highly resinous and affords TURPENTINE and TAR. Tapping is done by vertical cuts as in the long-leaved pine. The trees are tapped for about three years, then allowed three years' rest, after which tapping can recommence on another side. The more highly resinous parts of the wood are much employed for torches, which are known as *mashál* in Hindustani and Panjábi, *jagni* in Pushtu. The resinous cones are valuable for lighting fires. In certain dry winter seasons, the leaves and twigs become covered with a copious, sweet exudation. The "Manna" thus found is collected and eaten by the Natives. Gamble states that the Wood is good, and very largely used in construction throughout the Western Himalaya, and that it is also exported to the plains. For planking, doors, windows and furniture it is better than *deodar* (*Cedrus Libani*, var. *Deodara*) as it is less brittle, has not the oil, which in the *deodar* absorbs dirt, while it is free from strong scent. In Kangra and Kullu it is said to be used for tea-boxes. [Cf. Thurston, *Resin and Turpentine from Ind. Pines*, *Imp. Inst. Handbook*, 1893, 7-19; *Ind. For.*, 1893, xix., 367, 407; 1894, xx., 92-4; 1897, xxxiii., 282-9; 1900, xxvi., 497-503; 1905, xxxi., 369-72; Lawrence, *Valley of Kashmir*, 1895, 80; *Agri. Ledg.*, 1896, No. 14, 98; *For. . *erardiana*, Wall. The Neosia or Edible Pine, *gunober*, *rhi*, *newr*, *kannucht*, *shangti*, *ronocha*, *chiri*, *prita*, *galboga*; seeds = *chilgorza*, *neoa*, *zanghóz*. A moderate-sized evergreen tree of the inner, dry and arid North-West Himalaya, generally between 6,000 and 10,000 feet; mountains of Northern Afghanistan and Kafirstan; also Hariab district at 7,000 to 11,000 feet (Gamble).

The chief product of this species is the almond-like seed, contained in the cones. The cones ripen in October, are plucked before they open, and heated to make the scales expand. The seeds are then removed, and are largely eaten by the Natives and stored for winter use. In Kunáwar, they are said to form a staple food with the inhabitants. They are also exported to the plains, from the hills of the Panjáb, and large quantities are imported annually into India from Afghanistan. The wood is hard, durable and very resinous, but rarely utilised since the tree is so highly valued for its seeds. [Cf. *Pharmacog. Ind.*, 1893, iii., 379-80; *Agri. Ledg.*, 1896, No. 14, 96-7.]

. *hasya*, Royle. The *dingsa*, *tinyu*, *taru*. A large evergreen tree of the Khasia hills, hills of the Lushai country of Chittagong, Shan hills and hills of Martaban in Burma at 3,000 to 7,000 feet.

The resin of this species is perhaps the most valuable obtainable from any species of the genus. Samples were reported on by Armstrong (*Imp. Inst. Tech. Repts.*, 1903, 167-9). The crude turpentine, which is a grey, thick, pasty mass, furnishes by distillation with steam about 13 per cent. of its weight of oil. On a former occasion Armstrong obtained from a sample of *P. Khasya* 17 per cent. of oil. The original turpentine and the distilled oil have a slight but agreeable odour, less pronounced than that of French turpentine. Chemical examination also proved that the oil of *P. Khasya* is strictly comparable to French oil of turpentine, and Armstrong states that in his opinion the oil is of the highest quality and will be found to serve every purpose for which oil of turpentine (French or American) is used. Samples submitted to a London firm of brokers (*Agri. Ledg.*, 1896, No. 14, 102) were valued at £4 to £6 per ton for the crude turpentine, and at £24 per ton for the refined sp^t, while the res^t

obtained was valued at £5 to £6 per ton in London. At present, however, it appears that the area of forest is too small to make the industry of much importance in Assam, while in Burma the distance from the rivers and coasts of the chief forests precludes its profitable extraction at the figures quoted. [Cf. Thurston, *l.c.* 19-22; Scott, *Gaz. Upper Burma and Shan States*, 1900, i., pt. 2, 317-8; 1900, ii., pt. 1, 318-9; Max and Bertha Ferrars, *Burma*, 1900, 116; Tschirch, *Die Harze und die Harzbehälter*, 1906, i., 594-5.]

erkusli, *Jungb. & de Vriese*. The *tinyú, htenríú*. A large evergreen tree of the hill forests of the Shan States, Martaban and Tenasserim, at 500 to 3,500 feet.

The resin of this species was examined by Armstrong at the same time as that of *P. Khasya*. The crude turpentine is more fluid and clearer and yields nearly 19 per cent. of oil. The two oils closely resemble each other in all respects, and correspond exactly in their properties to French oil of turpentine. [Cf. Thurston, *l.c.* 22-3; *Agri. Ledg., l.c.*]

P. lo ifoli, *Roxb.* Long-leaved or Three-leaved Pine, *salla*, *D. J.P.,*
chír, dhúp, gniét, teadoug, kolam, sapin, nashtar, ranzuru, gula, thansa; *vi., pt. i.,*
oleo-resin = *gandabiroza, chír-ka-gond, koto*, etc. A large, more or less *4 -7.*
deciduous tree of the Outer Himalaya and Siwalik Range, also valleys of *Long-*
the principal Himalayan rivers at 1,500 to 7,500 feet; extending west to *leaved*
Afghanistan and east to Bhutan. *Pine.*

Resin.—This species is the chief tree tapped for resin. Tapping *Resin.*
in a systematic manner was commenced in Jaunsar, but has now ex-
tended both to the Panjáb on the west and to the forests of Kumaon on
the east. Gamble states that in 1888-9 about 9,600 trees were tapped
in Jaunsar, each giving about 8½ lb. of resin. The total yield of the year
was over 1,000 maunds resin, which produced at the Forest School Factory,
Dehra Dun, about 900 maunds of COLOPHONY and 1,740 gallons of TUR- *Yield.*
PENTINE, which sold for nearly Rs. 9,000. There are two methods of
tapping the trees, Native and European. The system employed by *Colophony and*
the hillmen of Kumaon and Garhwal is to cut a niche into the trunk about *Turpentine.*
3 feet from the ground, the bottom of which is hollowed out. The resin
is collected as the niche fills, sometimes every second or third day, usually
between the fourth and fifth days. The niche has to be deepened and
lengthened from time to time, and the same niche may be used for two
or even three years. By the European method an incision about 1 foot
long, 4 inches wide and 2 deep at the base, not including the bark, is cut
into the tree, and a curved incision about 5½ inches long is made just
below that, into which a piece of zinc is inserted so as to form a lip from
which the resin may flow into a pot suspended beneath. The cuts are
renewed about twice a month. Of the manufacture of turpentine and
colophony from the crude resin a full account is given by Birbal (*Ind.*
For., 1900, xxvi., 497-503). *Method of*
Tapping.

At the present day the Government are the only producers of resin
and turpentine in India, and the supplies come through the Conservators
of Forests in the Panjáb, Central Circle, School Circle, United Provinces,
Dehra Dun. [Cf. *Proc. Dept. Rev. and Agri.*, May 1905, Nos. 12-3.]
In 1901-2 the outturn of resin, colophony and turpentine was as follows:—
In the Panjáb (*For. Admin. Rept. Pt.*, 1901-2, 15), 63,188 trees were
tapped, and yielded 495,850 lb. resin, 256,824 lb. colophony, 7,081 gallons
turpentine; in Naini Tal (*For. Admin. Rept. U. Prov., Cent. Circ.*, 1901-2,
14), 38,632 trees, yielding 222,300 lb. resin, 88,888 lb. colophony,
2,204 gallons turpentine; in Dehra Dun (*For. Admin. Rept. U. Prov.,*
School Circ., 1901-2, 8), 14,420 trees, yielding 135,500 lb. resin, 103,976 lb.
colophony, 2,693 gallons turpentine. In 1903 turpentine was sold by the

Sour. of
Supply.

Price. Conservator, Central Circle, United Provinces, at Kathgodam railway station, for Rs. 2-4-0 per gallon, and colophony, at Cawnpore, for Rs. 4-8-0 to Rs. 4-12-0 (10 to 11 annas represents carriage to Cawnpore) per maund of 82 lb. The average price in the Panjáb Circle was Rs. 6-14-0 per maund at Amritsar for crude resin, Rs. 1-14-0 per gallon at Amritsar for turpentine, Rs. 3-3-3 per maund at Calcutta and Amritsar for colophony. The colophony is sold chiefly for soap manufacture, and the turpentine is in great demand for various industries, but chiefly in railway workshops. Indian resin is softer than ordinary trade samples : to overcome this defect it has been recommended to heat the resin more completely during distillation (*Bhaduri Rept., Labor. Ind. Mus.*, 1902-3, 22-3; also Hooper, *l.c.*, 1903-4, 25).

Soap.

Soft Resin.

Tar. The roots of felled trees are also utilised in the manufacture of TAR, which in Jaunsar has for some years been systematically prepared in closed masonry kilns. The tar is boiled down into pitch and exported to the plains for sale. The needles were found on distillation to yield only 0.1 per cent. of the essential oil. They contained a large proportion of resin, and their fibre was found unsuitable for paper-making. The leaves yield no nitrogen and less mineral matter than straw. They, however, constitute a good litter for stables and cattle-sheds (Hooper, *l.c.*, 1904-5, 26; 1905-6, 31).

Essential Oil of the Needles.

Trade. *Trade.*—The foreign IMPORTS of India in resin, during 1904-5, amounted to 49,003 cwt., valued at Rs. 2,98,073; in 1905-6 to 64,602 cwt., valued at Rs. 5,51,279; and in 1906-7, 96,486 cwt., valued at Rs. 8,82,060. In recent years the United Kingdom has been the chief source of supply, and in 1906-7 contributed 66,203 cwt., followed by the United States, 16,416 cwt., and then by Germany, 12,895 cwt. The EXPORTS in 1904-5 amounted to 1,918 cwt., valued at Rs. 37,515, and in 1906-7, 60 cwt., valued at Rs. 1,815.

[*Cf. Ind. For.*, 1891, xvii., 23-8, 157-61; 1892, xviii., 261-2; 1893, xix., 407-11; 1894, xx., 4-5; 1895, xxi., 279; 1896, xxii., 72-4, 146; 1899, xxv., 43; 1904, xxx., 308-11; 1905, xxxi., 5, 425-34; *Pharmacog. Rev. and Agri.* (Forests), Oct. 1903, (A) Nos. 6, 7; May 1905, Nos. 5, 6, 12-3; June 1905, No. 28; *For. Admin. Repts. Pb. and U. Prov.*; *For. Working Plans, Pb. and U. Prov.*; Schimmel & Co., *Semi-Ann. Repts.*; Tschirch, *Die Harze und die Harzbehälter*, 1906, i., 594.]

D. P. **PIP**, *Linn.*; *Fl. Br. Ind.*, v., 78-97; Gamble, *Man. Ind. Timbs.*, 1902, 554; Prain, *Beng. Plants*, 1903, ii., 892-3; PIPERACEÆ. A large genus of shrubs, rarely herbs or trees, some 45 of which are natives of, or naturalised in, India. Several are of great economic interest and value.

Chaba. *Chaba*, *Hunter, As. Res.*, 1807, ix. 391-2; *cháb, chavi, kankala*; wood and roots = *chaikath*. A native of the Moluccas, cultivated in India for its fruit, the *chaba* of Indian MEDICINE. The wood and root are used in Bengal for DYEING and give a pale brown on cotton if used alone, but mixed with *bakam* (*Cesalpinia Sappan*), a brownish-red. [*Cf. The Bower Manuscript* (Hoernle, transl.), 1893-7, 81, 94, etc.; *Pharmacog Ind.*, iii., 176; Dutt, *Mat. Med. Hind.*, 1900, 244, 295.]

Cubebs. *Cubeba*, *Linn., f.*; Cubebs, *kabáb-chini, timmue, luit-marz, himsi-míre, tada-miri, dumki-mirchi, val-mellaghu, chalavamiriyátu, bála menasu, komunkus, sinban-karawa*, etc. A native of Java and the Moluccas, cultivated to a small extent in India, and the fruit imported. It yields an unimportant gum-resin. The fruit, known as cubebs, has been used in European MEDICINE from the Middle Ages, and yields a thick, colourless essential OIL, with an aromatic odour and flavour of camphor and peppermint. [*Cf. Acosta, Tract. de las Drogas*,

1578, 113; Linschoten, *Voy. E. Ind.*, 1598 (ed. Hakl. Soc.), ii., 130; *Pharmacog. Ind.*, iii., 180; Gildemeister and Hoffmann, *Volatile Oils*, 1900, 322.]

. longu, Linn. Long Pepper, *pipulmūl*, *pipal*, *rālī*, *filfil daráz*, *tippili*, *yippali*, *lada*, *mulagu*, *peik-khyen*, etc. A perennial shrub, native of the hotter parts of India from Nepal eastwards to Assam, the Khasia hills and Bengal, westwards to Bombay, and southwards to Travancore, Ceylon and Malacca. As manifesting antiquity of knowledge, it may be mentioned that the Sanskrit name *pippali* was originally given to this plant, and only within comparatively recent times had been transferred to black pepper. Long pepper is mentioned by Pliny (Holland, transl., bk. xii., ch. 7), and is referred to in the *Periplus* (1st century).

Long
Pepper.

Long pepper is cultivated in Bengal and South India, and is the pepper chiefly exported from Calcutta. It is propagated by suckers and requires a rich, high, dry soil. The suckers are transplanted after the periodical rains set in, at a distance of 5 feet from each other. Each *bigha* is said to produce 2 maunds of pepper the first year, 4 maunds the second, 6 maunds the third, after which the roots are grubbed up, dried and sold. The plants require no irrigation, but at the commencement of the hot season the roots are carefully covered with straw to preserve them from the heat. Radishes, barley, or *brinjals* (*Solanum Melongena*) are usually cultivated in the space between the plants. The fruit is gathered when green in January, and is preserved by drying in the sun. The dried unripe fruit and the root have long been used in MEDICINE. [Cf. *Pharmacog. Ind.*, iii., 176; *The Bower Manuscript*, l.c. 78, 80, 88, etc.; Gildemeister and Hoffmann, *Volatile Oils*, 1900, 322; Dutt, l.c. 243-4.]

P. etle, Linn.; Hunter, *As. Res.*, 1807, ix., 390-1; *Bot. Mag.*, 1832, 3132. The Betle, *pán*, *támbulī*, *tambula*, *vilyadele*, *videcha-pána*, *nágurvel*, *vettilai*, *nágavalli*, *viledede*, *kúnyoe*, etc. A perennial dioecious creeper, probably native of Java; cultivated for the sake of its leaves in the hotter parts of India and Ceylon.

D. P.,
vi., pt. i.,
247-5 .
Betle.

istory.—According to *Hobson-Jobson* (ed. Crooke, 89) the word *belle* is the Malayan *vettila*, i.e. *veru-ila*, which means "simple or mere leaf" and comes to us through the Portuguese *betre* and *bette*. The Natives of India and the Indo-Chinese countries have from remote times been in the habit of chewing the leaf, generally mixed with areca-nut, lime, and catechu in the case of the poorer classes, with cardamoms, nutmegs, camphor, etc., in that of the rich. Marco Polo (ed. Yule, ii., 306, 311), in the 13th century, writes that the people of India have a habit of keeping in the mouth "a certain leaf called *Tembul*," and adds that the richer classes and the King have these leaves prepared with camphor and other aromatic spices, as well as quicklime. In 1442 Abd-er-Razzak, in the narrative of his journeys in the East, thus describes the method of eating it. "They bruise a portion of *faufel* (Areca), otherwise called *sipari*, and put it in the mouth. Moistening a leaf of the betel, together with a grain of chalk, they rub the one on the other, and roll them in the mouth. They thus take as many as four leaves of betel at a time, and chew them. Sometimes they add camphor to it, and sometimes they spit out the saliva, which becomes of a red colour." Garcia de Orta (*Coll.*, x.), writing in 1563, corroborates these facts, stating that the Indians are in the habit of keeping the nail of the right thumb pointed and sharp, in order to remove the midrib of the leaf. Many of the other early travellers refer in similar terms to the practice of chewing the betle-leaf. [Cf. *Narrative of Journ. of Abd-er-Razzak*, 1442, in *Ind. in the 15th Century* (ed. Hakl. Soc.), 32; Linschoten, *Voy. E. Ind.*, 1598 (ed. Hakl. Soc.), ii., 62-8, etc.; Pyrard, *Voy. E. Ind.*, 1601 (ed. Hakl. Soc.), ii., 362-3; Bernier, *Travels*, 1656, in Constable, *Or. Misc.*, i., 13-4; Barbosa, *Coasts E. Africa and Malabar* (ed. Hakl. Soc.), 73; Mandelslo, *Travels*, in Olearius, *Hist. Muscovy*, etc., 1662, 42; Fryer, *New Acc. E. Ind.* and *Pers.*, 1672-81, 40; Diary of W. Hedges, 1681-7 (ed. Yule), ii., cccxxxi.; Hamilton, *New Acc. E. Ind.*, 1727, i., 304; Joret, *Les Pl. dans L'Antiq.*, etc., 1904, ii., 261.]

Pán.

CULTIVATION.—The cultivation of betel-leaf is attended with many difficulties; it requires a constant temperature, a fairly uniform degree of moisture, and much attention on the part of the cultivator. The plant is propagated by cuttings or sets grown under shade, and in many parts of India within specially constructed houses of grass, reeds or mats having

Cultiva-
tion.

flat grass roofs so designed as to admit of a diffused light. The plants are grown in parallel rows that allow spaces for the owner to pass between, but nothing more. In other cases, the vines are cultivated under the shade of trees, very often the areca-nut palm or other trees specially grown for the purpose, and planted in the form of a compact garden surrounded by a protecting hedge. *Pan*-leaf is hardly ever grown by the consumer, but is regarded as a special cultivation that requires expert knowledge. The methods pursued vary considerably in different localities, and may be best considered under the names of the provinces in which the leaf is chiefly produced; but unfortunately statistics are not available for all provinces, and only for certain years of those that are returned.

Bengal.—As far as can be estimated, the area under the betel-vine in 1904-5 exceeded 43,000 acres. The greatest possible confusion has existed regarding the varieties and races met with in this province. The commercial value of one form of *pan*-leaf is so infinitely greater than another that the comparison between them (in point of price) is as great as that between the produce of the very poorest and the very finest vineyards. A uniform rate of rental for land yielding so entirely different products would obviously be unjust.

The following information regarding the methods of cultivation is abstracted mainly from Mukerji and Roy. There are three main varieties—*deshi*, extensively cultivated in Central and Southern Bengal; *gach*, cultivated in North Bengal; and *sanchi*, cultivated to a smaller extent all over the country. According to the former writer, the finest *pan* is grown at Bantul, half-way between Ulubaria and Midnapur, on a light loam slightly reddish in colour. Ordinarily a black, friable clay loam, containing a large proportion of organic matter, and situated above inundation-level, is chosen for the crop. After selecting the site, shrubs and trees growing on it are uprooted or burned down and a trench is dug round, the earth obtained being spread over the surface of the garden. Before planting the betel-vines, a roofing is manufactured for the purpose of securing shade, evenness of temperature and security from high winds. Rows of bamboo or other stakes are planted, $4\frac{3}{4}$ cubits remaining above ground. Over these are placed *dhaincha* or jute-stalks and sometimes a thatch of *ulu*-grass. The garden is fenced round with the same materials. Each row of cuttings is planted between two lines of stakes, with intervals of 6 inches between the cuttings. Cuttings are taken from plants two years old or more. These are made of lengths 12 to 18 inches, each with five or six joints, two of which are buried in the earth, while the portions left above ground are made to recline on the surface. They are then covered with date-leaves and watered morning and evening till they strike root and put forth buds. Planting time is May to November. Occasionally cuttings are first planted in nurseries, and, when rooted and have sent forth new leaves and buds, are transplanted. As the plants go on increasing in length, one or two jute-stalks are stuck in the ground close to each, the upper ends reaching the roof, and the betel plants are tied to them by *ulu*-straw. When the plants reach the roof they are bent downwards, a portion is made to rest on the ground and is covered with a little earth, while the bud end is again bent upwards and tied to another support. This process is repeated about three times a year, and every time a few leaves are plucked away at the points where bending takes place. Pond-mud and other kinds of well dried and pulverised earth are placed between

PAN-HOUSES

P
TL
Cultivation

the lines and used to earth up the plants. Each time earthing-up takes place, dried and pulverised pond-mud, cow-dung, and oil-cake are used as manure.

If planting is done in July–August, plucking commences in October–November, but if planting be done in October–November, plucking takes place in May–June. Two pluckings are made each month. Two to four leaves are got on each occasion, and in the rains four to six leaves a plant. The plants are in full bearing for some five years, at the end of which time the garden or *baroj* requires to be thoroughly overhauled. Mukerji gives the outturn from one acre as about 80 lakhs of leaves per annum, and the total cost per acre for a period of three years as Rs. 1,422. Taking 3,000 leaves per rupee as the average price of *pan*, Mukerji estimates the outturn of leaves at Rs. 2,500.

[Cf. Basu, *Agri. Lohardaga*, 1890, pt. 1, 83; Banerjee, *Agri. Cuttack*, 1893, 96–9; Chaudhury, *Note on Piper Betel in Backergunge*, Nov. 1898; Mukerji, *Handbook Ind. Agri.*, 1901, 429–33; Roy, *Crops of Bengal*, 1906, 170–4.]

United Provinces.—H. R. Nevill states that the plant thrives best on a stiff soil, retentive of moisture, and says the site selected for the garden is generally an elevated spot with a good slope. The land is ploughed, levelled and thoroughly cleaned, and then enclosed with stakes and brush-wood and covered with a roof of *sentha*-grass. Shallow trenches are next scooped out, 2 feet wide by 5 or 6 inches deep and 5 feet apart, which are filled with water; and when the soil is saturated, planting commences. Full-grown plants, stripped of their leaves, are cut down close to the root and divided into three or four portions, which are laid horizontally in the trenches and covered with earth. In a few days sprouts appear at each knot. Planting goes on from February to April, and each row is watered two or three times a day. Stripping the leaves begins about the middle of June and is continued regularly for about a year, after which the plant is exhausted and is used for stocking a fresh plantation while the old garden is allowed to rest for a year or two. The leaf is sold in bundles of 200 called *dholis*, the price varying according to age and quality. [Cf. Duthie and Fuller, *Field and Garden Crops*, pt. iii., 51–3, tt. 91, 1a; Nevill, *Dist. Gaz. U. Prov.*, 1904, xlvii., 36–7.]

Central Provinces.—In the Central Provinces one of the forms most highly prized and sent very largely to Calcutta is known as the *kafuri*. In the *Settlement Report* of Wardha the method of cultivation is fully described. The leaf is cultivated by a class of people called *burehs*, and the garden is known as *bureja* or *pan-ka-tanda*. The *pan*-gardens are generally held by a cultivating brotherhood, forming an independent section in the village and paying rent to the landowner through the head of their body. A portion of the village land is recognised as belonging to this caste. The garden is enclosed on all sides with bamboo and mat coverings. The vines are planted in ridges, varying in length with the area of the enclosure, and the ridges are divided into a certain number of units of length, called *lani*, which are portioned off among the brotherhood. The plants require constant care, and much water and manure are also essential. In two years they cease to bear leaves of any marketable value, and new gardens are then made. The first year of cultivation is called *wotuk*, the second *korwa*, the produce of the latter being more esteemed and more sought after than that of the first year. At the end of the second year the ground is allowed to remain fallow for periods of two or three years.

In Nimár the method presents several interesting features. A garden once established is said to yield steadily for ten or twelve years. The ground is similarly prepared to that in Wardha, but trees are grown to afford shade, such as the *saora* (*Sesbania egyptica*). The plantation is also surrounded by poles of *pángrá* (*Erythrina indica*), to which bamboo mats are attached. After the *saora* trees die down, they are replaced by poles of the *salei* (*Boswellia serrata*). Meantime plantains have been set all over the garden, at intervals of 10 or 12 feet, for purposes of shade. No matting is used overhead or for partitions. Every year, after the leaves have been gathered, the creeper is coiled down at the root till only some 3 feet are left above ground. A fresh root is thus struck, and the old coil is next year cut away. The crop is irrigated at all seasons except during the rains, and at the commencement of each hot season (March) the plants are pruned, manure is applied to the roots, and fresh earth piled round them. Before the ten or twelve years are over, the garden soil thus increases in depth by about 2 feet. After that time the garden is removed, hemp is sown to clean the land, and alternate fallows and irrigated spring crops with liberal manure follow for some years to render the land again fit for *pán*. [*Cf. Rept. Land Rev. Settl., Nagpur, C. Prov., 1899, 68-75.*]

Bo bay.—The area under the crop in 1904-5 was returned as 3,958 acres, of which 1,343 acres were in Dharwar, 518 acres in Poona, 390 acres in Belgaum, 380 acres in Kanara, 372 acres in Satara, etc., and in the following year (1905-6) the total area was 4,048 acres. The system of cultivation differs in no essential particulars from the method followed in other localities. In Dharwar, *pán* is the most important garden crop. The shoots are planted in the open, trained on quick-growing trees, an acre of land containing upwards of 2,000 plants, and the crop lasts only four to seven years. The vines are then dug up, the leaves of the trees on which they were trained are used for vegetable manure, and the wood for fuel. The garden is deeply dug all over, allowed to lie fallow for one year, and afterwards planted with sugar-cane. After the sugar-cane, it enjoys another year of fallow, when betel plantations are again laid out.

In Poona, betel is also an important garden crop. It is grown on light red soils, requires much manure and constant watering, and if well cared for may last fifteen to twenty years. The garden generally covers about an acre, the vines are trained on various trees, planted in rows and pollarded, and the whole garden is sheltered by high hedges or grass screens or mats. Every year in March, April or May the upper half of the vine is cut, while the lower half is coiled up and buried under fresh red earth and manure.

In Kanara the plant is described as cultivated in gardens on mango-trees. The leaves are picked three years after planting the young shoots, and the yield is estimated at 100 to 200 leaves from a full-grown vine every fortnight. An acre of spice-garden containing 500 plants is said to produce some 40,000 leaves annually, worth Rs. 20 and costing Rs. 8 to grow.

Madras and Mysore.—The plant is widely distributed in the Presidency, being found chiefly in the moister regions. Cox (*Man. N. Arcot, 1895, i., 265-6*) fully describes the method of cultivation, which differs in no essential particulars from the methods already described. It is a three-year crop, grown on land capable of incessant irrigation. The

HEDGES AND SHADE-TREES

PIP R
TL
Cultivation

plants begin to yield when nine or ten months old, and continue to yield for two or even three years. The leaves are tied in bundles of 400 each, and the usual price of such a bundle is an anna. An acre in two years produces 5,000 to 7,500 of these bundles, worth Rs. 300 to 500. Yield.

In Mysore the cultivation is thus described by Rice (*Mysore Gaz.*, 1897, i., 160-2):—A black soil is required, and the plant thrives best in low ground where it can have a supply of water from a reservoir. Soil.
In the east (e.g. Chaitra or Vaisakha), the ground is trenched over 1 cubit deep and surrounded with a mud wall, within which a hedge, chiefly of *Euphorbia Tirucalli*, is planted. If there is not plenty of rain, it must be regularly watered for six months. The garden is then dug and formed into beds with a space of 20 feet between them and the hedge. By an elaborate system of channels for supplying and draining off water, the garden is divided into blocks. In the centre of each, a row of small holes is formed, 1 cubit distant from one another, and in December-January into each hole are put two cuttings of the betel-vine, each 2 cubits long. The middle of each cutting is pushed down and slightly covered with earth, while the four ends project and form an equal number of young plants, which for eighteen months are allowed to climb on dry sticks. For the first week after planting they must be watered twice a day, for another week once a day, and till the end of the second month once in three days. A small drill is then made across each division of the beds, and between every two holes in each, in which seeds of *agase* (*Sesbania grandiflora*), *nugge* (*Moringa pterygosperrna*), etc., are planted. The young betel-vines must have some manure, and for four months require to be watered once in three days. Hedged-in Garden.
Afterwards all the channels are filled with water once in four days. When a year and a half old, the plants are removed from the sticks. Two cubits of each next the root are buried in the earth and the remainder, conducted close to the root of one of the young trees, is allowed to support itself on the stem. At the end of two years, 2 cubits more of each plant are buried, and afterwards this is repeated once a year. At the end of the fourth year the cultivator begins to gather the leaves, and continues to obtain a constant supply for six or seven years. Drainage.
Planting.
Living Shade.
Watering.
Seasons.

In the west, the betel-vine is grown with the areca-palm. When the areca plantation is fifteen years old, in the month following the vernal equinox a hole is dug near every tree, one cubit deep and one and a half wide. After the earth has been exposed for a month, it is returned to the hole and left for another month. A little earth is then taken out, the surface smoothed and the ends of five cuttings of betel-vine buried in it. For a month they are watered once every two days, and shaded with leaves which are afterwards removed, and the earth in the holes stirred with a stick. In the first year, the waterings are repeated every day, and the whole must be hoed once a month and manure given to each plant. In the second year, the vines are tied to the palms, and the garden hoed and manured once in two months, but watered only in the hot season. At the end of the second year, the vines begin to produce saleable leaves. In the third year and every year after, the part of the vines without leaves next the root is buried. Once in six months the garden must be hoed and manured, and watered every other day during the hot weather. [Cf. Sturrock, *Man. S. Canara*, 1894, i., 206-7.] Planting.

cultivation. The following account from the Sagaing district is given by Parlett (*Rept. Settl. Operat. Sagaing*, 1903, 130-1). Small plots planted with betel-vines are found in most Sagaing gardens. At Tada-u, where land is devoted solely to raising betel, a site is chosen usually under tamarind-trees, and occasionally a few plantains or other trees are grown for shade. The gardens are divided into blocks, some 30 feet square, and the plants set in rows about 2 feet apart in each direction, connected by small water-channels. Between every six or eight rows is a pathway (*yin-gwe*) about 3 feet wide. The vines are always irrigated from wells and in the hot season are watered alternate days : in the early rains at intervals of two, and in the cold weather, of three days. While rains are continuous, irrigation ceases. A top-dressing of leaf-mould every year is said to improve the yield. Leaves may be gathered within a year after planting, but plucking is often deferred to the second year, and the third to fifth years are best. After the sixth year the vines are often cut down. In Sagaing old or weakly vines are cut down from year to year and replaced by new slips, and the same ground is occupied by the vinery for twenty years or more. In Tada-u the garden is worked as long as it is remunerative ; then the vines are cut down and the land fallowed for two years. Each block is usually plucked once a month or once in two months, always before 9 a.m., as plucking in the heat of the day exhausts the vine. The average price of young plants is Rs.15 per 1,000 ; of the leaves, Rs. 25 per 100 viss. The average mortgage price works out to Rs. 226 per acre, and the annual rent to Rs. 100 per acre. The ground-rent per acre averages Rs.113 for the life of the vine—five years—or about Rs. 22 a year. It is estimated that 1,000 vines yield an average annual profit of Rs. 35, i.e. Rs. 350 per acre. [*Cf. Upper Burma Gaz.*, 1900, ii., 344.]

TRADE IN PÁN-LEAF.—The habit of chewing this substance is very widespread, especially in the towns and cities, the supplies being often drawn from great distances. The Central Provinces send a large portion of their produce to Calcutta on the one side, and Bombay on the other. Neither in the official returns of trade by rail and river, nor by sea coastwise, is there any mention of *pán*-leaf, so that no information exists as to the extent or direction of the internal movements. There are no foreign transactions.

CULTIVATION.—Pepper was one of the most important articles of early Indo-European trade, and has been extensively cultivated on the western coast of South India from very early times. Vincent (*Periplus etc.*, 1800, app., 42) speaks of it as grown in Malabar. It has accordingly been specially cultivated there since at least the 5th century. But : much earlier knowledge is shown by the frequent mention of pepper by the Sanskrit medical writers. It was also known to the Greeks from the time of Theophrastes onwards. Though cultivated from remote time in Sumatra, the Straits, Siam, and the Malay Peninsula generally, Malaba

BLACK AND WHITE PEPPER

PIP

Cultivation

has always been considered to produce the best pepper. The provinces where pepper is most extensively grown to-day are Madras and Bombay. Hanausek (*Micro. Tech. Prod.* (Winton and Barber, transl.), 1907, 374) states that pepper is adulterated with ground olivestones.

engal.—Pepper is cultivated to a limited extent only in the northern parts of Jessore. Elsewhere in Bengal it grows wild during the rainy season. "The creeper is planted in the beginning of the rains, and as it grows in the shade the seeds of the stout *dhunecha* hemp plants are sown near it to afford shelter as they grow." [*Cf. Admin. Rept. Beng.*, 1901-2, 17.] **Bengal.**

Assa .—Basu (*Agri. Ledg.*, 1898, No. 7) gives a full account of the cultivation of black pepper in Assam. The crop, it would appear, is not cultivated appreciably in any particular part. A little, however, is found in Sylhet and on the southern slopes of the Khasia hills. It is usually grown to meet home requirements, and what is left over is sold. Like the betel-vine, it is commonly raised on betel-nut palms (*Areca Catechu*), while the mango, jack, and other garden trees are occasionally utilised. It is propagated either from suckers, which spring from underground roots, or from shoots from the stem. When shoots are used, they are bent down into the ground to strike root before they are severed from the mother-plant. The young plants are generally uprooted at the beginning of the rains, and planted at the foot of the trees on which they are to grow—as a rule one plant only is placed along side of each tree, and at first it has to be carefully tied to its support. Like the betel-vine, it requires liberal manure; cow-dung and household refuse are used and applied at the end of the rains and at intervals through the cold weather. This is simply heaped round the base of the tree on which the vine climbs; and to keep the moisture in the manure-heap, pieces of the leaf-sheaths of the plantain-tree are laid over the top and renewed from time to time. The plantation must be hoed and cleaned once a year at the close of the monsoon rains, and in May the manure-heaps are levelled down and spread over the ground. The vine begins to bear in from three to five years after planting, and continues for at least twenty years. It flowers in May and the berries are plucked in December, when just beginning to ripen. **Assam.**

If intended for the cultivator's use, the berries are boiled in water for a few minutes to soften the husk, which is then removed by rubbing over a bamboo basket. If intended for the market, they are simply dried in the sun after boiling and allowed to retain the husk, which assumes a black colour. The highest outturn that can be obtained from a single vine is said to be about 3 seers of dry cured pepper, and the average yield about 1 seer for each vine in a plantation. The retail price for Assam black pepper varies from 10 annas to a rupee per seer, and the wholesale price from Rs. 17 to Rs. 20 per maund. [*Cf. Basu, Cult. Black Pepper Assam*, in *Agri. Dept. Assam Bull.*, 1898, No. 4.] **Propagation.**

o bay.—The area under the crop in 1904-5 amounted to 6,736 acres, and in 1905-6 to 7,483 acres, practically the whole of which was in Kanara. The following information is mainly abstracted from Mollison (*Agri. Ledg.*, 1900, No. 3; 1901, No. 3). The plant is propagated by layerings or from cuttings. When the betel-palms are seven or eight years old, pepper is planted at the bottom of the stems. A long, healthy shoot from an established plant is layered in the leaf-mould surrounding the palm on **Seasons.** **Manure, Farm-yard.** **Crop.** **Preparation for Market.** **Yield.** **Price.** **o bay.** **Area.** **Prop ation.**

which it is intended to climb. When it has taken root it is severed from the parent plant and trained on its living support. Two or three shoots are sometimes layered to one palm. The best months for propagating are June and July. The main vine should divide freely into subordinate branches so that a number of shoots can be trained to ascend. They are secured to the stem by bands stripped from the sheaths of fallen leaves of the betel-palm. Heavy applications of good manure are given annually for three years after planting. Subsequently the pepper participates in the general cultivation given to the betel, and an application of manure is made to both crops every second year. The manure is heaped over the bared roots of the betel-trees and pepper-plants in a circle round the stem. The best manure is made from green leaves and twigs plucked in the monsoon, used as litter in cattle-byres, and thence removed to a manure pit every day or second day, together with the dung and urine of the cattle. This manure is sufficiently decayed by the following March, and is applied in that month or in April. A plantation is in bearing three or four years after it is started, and if the old vines as they get worn out are at once replaced by new layers, the plantation will keep in vigorous growth for a long period. Flowers appear in July and August and the berries are ripe in March. The vines, in full bearing, give in a good season about 1,000 clusters, which should yield about 7 seers of dried pepper (1 Bombay seer = 7 lb.).

Ordinarily the bunches are plucked when the berries are green or changing colour. The berries are then sorted out, the ripe ones separated, soaked in water for seven or eight days, or heaped till the pulp ferments. They are then rubbed or trampled underfoot till the pulp is rubbed off the "stone" which furnishes the white pepper of commerce. But that article is prepared, to a small extent only, in Kanara. The chief product is black pepper, which is got from unsorted berries. These are heaped for about four days till such as are green get soft and change colour, and the pulp of all is more or less squashed. They are then spread out and dried. The skin and part of the pulp adhere as a dark, wrinkled covering to the stones, and the pepper is black in appearance. White pepper is worth Rs. 10 to 11 per maund, and black Rs. 7 to 8 per maund. [*Cf. Dept. Land Rec. and Agri. Bombay Bull., 1900, No. 20, 13-5.*]

Madras and Mysore.—In certain respects it might almost be said that we know very little more regarding the pepper industry of South India than was understood in the first and second decades of the 16th century. Varthéma (*Travels*, 1510 (ed. Hakl. Soc.), 1863, 157) will be found to give a vivid picture of the plantations in and around Calicut:—"It is like a vine climbing on trees: from each of the branches are produced five to eight clusters of berries, a little longer than a man's finger; they are like raisins but more regularly arranged, and are as green as unripe grapes; they gather them in October and November, and lay them in the sun on mats, when they turn black as they are seen among us, without doing anything else to them. And you must know that these people neither prune nor hoe this tree which produces the pepper." So also Barbosa, in the beginning of the 16th century (*Coasts E. Africa and Malabar* (ed. Hakl. Soc.), 1866, 219), gives a detailed account of the plant, and of the trade in pepper from Calicut shortly after the arrival of the Portuguese in India. The spice had to pay an export duty to the King of Calicut and was shipped *viâ* Cambay to Persia, Aden, Mecca, Cairo and Alexandria,

MALABAR PEPPER

PIP R
NI U
Cultivation

thence to Portugal. Mandelslo (*Travels*, in Olearius, *Hist. Muscovy*, etc., 1662, 93, 111) gives certain particulars of the pepper cultivation of the "Cuncam or Decam." He states that the traffic goes *via* Surat.

According to modern writers the method of cultivation presently pursued is very simple. Cuttings are put down during the rains in June-July, in rich soil, not subject to excessive moisture, and liberally manured, not with cow-dung as in Bengal and Assam, but with leaf-mould. The trees selected as supports are mostly those which have a rough or prickly bark, such as the jack-tree, the *murukku* (*madar*, p. 523), etc. The vines may grow to 20 or 30 feet, or even higher—they are never pruned. All suckers are removed and the ground around kept clear of weeds. In three years the vine begins to bear. From the third to the seventh year the plant improves. After that it remains in good condition for three or four years, and then deteriorates for about the same period, when it is cut down and new shoots planted. The fruit is gathered as soon as the berries at the base of the spike begin to change colour. [*Cf. Kew Bull.*, 1895, 178-80.]

In April of 1905 a Government farm, under the superintendence of Mr. C. A. Barber, Government Botanist (for the scientific study of the cultivation of pepper), was started at Talliparamba near Tellicherry, which may be spoken of as the centre of the South Indian (indeed of the Indian) pepper production. A very large amount of work has already been accomplished, of which Barber has published as yet only a brief note (*Agri. Journ. Ind.*, i., pt. ii., 163-4). "Any one," he observes, "at all conversant with a plantation of black pepper, will have noted the great variation in the bearing power of different vines." This is a consequence of some plants bearing wholly male (staminate) flowers, others only female (pistillate) flowers, while still a third possess both stamens and pistils, but the former so sparsely as to lessen fertility. "In choosing vines for propagation, it will, therefore, be necessary to first determine whether the plant is fully provided with stamens." "It may be taken as a rule that any vine, if fully provided with stamens, will give a good crop, while any vine not so provided will be capricious in its behaviour, being dependent on its neighbours for the swelling of its berries."

Barber (*Varieties Cult. Pepper*, in *Dept. Agri. Mad. Bull.*, 1906, iii., No. 56, 126-32, tt. 1-3) says that there are "three main types of good vines freely provided with stamens, the *Balamcotta*, *Kallivalli* and *Cheriakodi*. Each of these has variations in all directions."

alamcotta.—This is all round the best pepper, is widely distributed, and apparently the main Tellicherry variety. The leaves are the largest of all. Its general colour is light green, and when full grown is twice as long as broad, oval to ovate, broadest at the middle and one side frequently broader than the other. Flowering branches, drooping. Spikes long, usually up to six inches, and the individual flowers distant. It is a strong-growing plant, flushing all over at the same time, and a heavy bearer.

allivalli.—This has the reputation of being a heavy bearer, but the flushing is irregular. The leaves are fairly constant, but vary in width according to age. In general colour they are dark green, and the veins much more deeply impressed, almost corrugated, than in *alamcotta*. Flowering branches stand out stiffly and joints close together. Spikes shorter than in *alamcotta* and frequently seen branched; sometimes, in fact, the spikes appear tassel-like. The flowers are also a good deal closer

together, and though abundantly supplied with stamens, yet the plant may be spoken of as less fixed as a type.

Dwarf Form.

Leaves
arranged
definitely.

Cheriakodi.—This name is given to a well-marked variety, small in all its parts—a dwarf form, under 15 feet in height. The leaves are not large and the spikes are small and crowded with small berries. The leaves are arranged uniformly over one another like the tiles of a house, almost vertically downwards, and thus hiding a large number of spikes.

Under each of these main forms there are several recognisable races as well as two well-marked *jungle peppers* that have found their way into estates. These are characterised by dark-green leaves, very large berries, and an immense growth on tall forest-trees, and usually hairy spikes.

Diseases
and Pests.

Wilt.

Diseases and Pests.—Until quite recently very little had been published on these subjects. Butler (*Agri. Journ. Ind.*, i., pt. i., 30–6) gives an instructive account of the Pepper Wilt. He suspects this disease first appeared in the Wynaad district of Malabar about 1900. By 1904 he found alarm general. The disease had produced a vast amount of damage in three or four years. “Its possibilities in this direction,” says Butler, “are evident from the fact that over four thousand acres of pepper cultivation are in the hands of Europeans in South Wynaad, and perhaps five times as many are grown by Natives. A far greater amount is grown in the coast districts of Malabar, but it is impossible to estimate how much this may be.” He then describes the appearance of the diseased plants. The leaves first droop, the production of leaf is discontinued, the stems of the vine separate from the support or standard owing to the decay of the clinging roots, the leaves turn yellow and fall off, and lastly the whole vine withers. A similar disease appeared in Cochin-China and Java about the same time as in India, and was attributed by Prof. W. Zimmermann and Dr. van Breda de Haan to the parasitic worm *Heterodera radiculicola*—the common root eelworm. Doubt was thrown by Barber and others on the possibility of the eelworm being the sole cause, and Butler, in the paper above indicated, has shown that the primary cause is a *Nectria* fungus closely allied to, if not identical with that discussed under *arhar*, *Cajanus indicus* (see p. 198). Butler concludes that a critical study of the varieties and races of the pepper-vine with a view to discover or produce a wilt-proof form, is the only satisfactory method of dealing with the disease.

rade.

T ADE.—The trade in pepper is perhaps the oldest, and during the Middle Ages was the most important branch of commerce between Europe and the East. In the early days, the Malabar Coast had a practical monopoly of the trade. Gradually, however, more and more pepper was cultivated in, and exported from, the Malay Archipelago, and localities farther east, till, as early as the beginning of the 19th century, the Indian production had shrunk into relative insignificance. The following gives a brief summary of the conditions of the trade.

TRADE IN PEPPER

PI TACIA
Kákrasingi

Internal.—The total registered transactions carried by rail and river during 1904-5 were 14,745,544 lb.; 1905-6, 15,203,216 lb.; 1906-7, 14,531,776 lb. Calcutta port and the province of Bengal are usually the chief IMPORTING centres, being followed in this respect by the Panjáb. In the last-mentioned year, Calcutta town took 2,686,768 lb.; Bengal province, 2,217,376 lb.; and the Panjáb, 1,500,128 lb. Of the EXPORTING centres, Calcutta again heads the list, having given 4,752,384 lb.; Madras Presidency, 3,654,448 lb.; Bombay port, 2,727,088 lb.; Madras ports, 1,454,096 lb.; and Karachi, 1,272,320 lb. The Calcutta and Bombay supplies are derived by rail and river as well as by sea coastwise. The chief exporting centres are Madras and Bombay, and naturally so, since they are the provinces of production. The Madras supply is, however, drained very largely from Travancore, and is consigned direct to Calcutta or Bombay; so also the production of the Madras Presidency (so far as returns of coasting trade show) is consigned almost entirely to Calcutta and Bombay. During the five years ending 1905-6 the imports averaged 16 million lb., of which Calcutta and Bombay ports each took 6½ million lb.

External.—The total EXPORTS of Indian pepper during the period 1900-7 were as follows:—1900-1, 8,280,372 lb., valued at Rs. 28,91,835; 1901-2, 13,589,172 lb., valued at Rs. 48,01,554; 1902-3, 9,310,166 lb., valued at Rs. 32,76,476; 1903-4, 14,348,983 lb., valued at Rs. 50,71,541; 1904-5, 10,113,416 lb., valued at Rs. 35,46,209; 1905-6, 17,889,994 lb., valued at Rs. 61,07,357; and in 1906-7, 9,499,089 lb., valued at Rs. 33,01,237. The chief exporting provinces are Madras and Bombay, which in 1906-7 exported respectively 7,722,866 lb. and 1,682,468 lb. The countries to which the exports chiefly go are Italy, which in 1906-7 took 2,263,912 lb.; Germany, 1,813,756 lb.; United States, 1,034,040 lb.; Great Britain, 757,311 lb.; Turkey-in-Asia, 719,501 lb.; Aden, 363,899 lb.; France, 338,758 lb.; Belgium, 112,000 lb., etc. The re-exports of foreign merchandise are unimportant—10,227 lb. in 1906-7. The IMPORTS of pepper into India come almost entirely from the Straits Settlements, which, in 1906-7, imported 990,564 lb. out of a total of 1,061,826 lb. The other countries from which India imports pepper are chiefly Ceylon and East Africa.

PI TACIA, Linn.; Fl. Br. Ind., ii., 13; Gamble, Man. Ind. Timbs., 1902, 210-1; Duthie, Fl. Upper Gang. Plain, 1903, i., pt. 1, 187; Brandis, Ind. Trees, 1906, 199-200; ANACARDIACEÆ. A genus of trees containing some six species, of which two only are natives of India. Several others occur in Afghanistan and Baluchistan and yield valuable articles of trade sent largely to India, besides some of the species being there occasionally cultivated.

P. hinjuk, Stocks, in Hook., Kew Journ. Bot., iv., 143; Duthie, l.c. 187; P. integerrima, Stewart, Gamble, l.c. 210. The North-West Himalayan form (*integerrima*) *kákra*, *drek*, *gurgú*, *tánhári*, etc.; galls = *kákrasingi*, *dushtapuchattu*; the Baluchistan form (*Khainjauk*) *ushgai* or *buzgai*, etc. A deciduous tree of the Suliman and Salt Ranges; outer Western Himalaya, up to 6,500 feet, extending east to Kumaon; chiefly on dry slopes and in river valleys.

The hard, rugose, hollow galls, which form in October, are used to a small extent for dyeing and tanning, and have long held a place in the Hindu *Materia Medica*. They contain 75 per cent. tannic acid and give a blue-black colour with ferric chloride. The leaves are lopped for fodder for buffaloes and camels. The wood is used for furniture, carvings and ornamental work. According to Gamble, it is generally sold in the hill bazárs, particularly at Simla, in the form of thick, short planks. [*Cf. Pharmacog. Ind., i., 374-7; The Bower Manuscript (Hoernle,*

P. Lentiscus, Linn. The Mastic Tree or Mastiche; resin = *rūmī mastikī*, *kūndur-rūmī*, *arah*, etc. An evergreen shrub of the Mediterranean region, which yields the mastic of Chios, imported into India.

The resin (mastic) occurs in small, irregular yellowish tears, brittle and of a vitreous fracture, but soft and ductile when chewed. It has been known in medicine and the arts from the earliest periods. It is used as a masticatory by people of high rank in India to preserve the teeth and sweeten the breath, and also in the preparation of a perfume. [Cf. Milburn, *Or. Comm.*, 1813, i., 139; Moodeen Sheriff, *Mat. Med. Mad.*, 1891, 114-6; Holmes, *Cat. Hanb. Herb. Pharmaceut. Soc. Mus. Rept.*, 1892, 29; *Kew Bull.*, 1897, 421-2; 1898, 190-1; 1903, 19-22; *Ind. For.*, 1898, xxiv., 480-1; Tschirch, *l.c.* 468-74.]

P. utica, Fisch. & Mey.; Lace and Hemsley, in *Ind. For.*, 1891, xvii., 449-50; Prain, *Rec. Bot. Surv. Ind.*, i., 130; *P. Terebinthus*, Linn., var. *mutica*, Aitch. & Hemsley, *Trans. Linn. Soc.*, iii., ser. 2, 47. The *gwan*, *khanjak*; resin = *mastikī*, *kunzad*, *wanjad*, *shilm*, etc. In the *Dictionary* this species is treated as the Asian representative of **P. Terebinthus**, the plant which yields the Chian or Cyprus turpentine, but it is now regarded as a distinct species. It occurs commonly in Baluchistan. The resin resembles that of **P. Lentiscus** and is used in the East as a substitute for that substance. It bears the same vernacular names, and is considered almost identical with that of **P. vera**. The leaves are very generally affected by a horse-shoe shaped gall, which extends round the margin and gets the name of *gosh-wāra* (ear-lobe) from its peculiar shape. According to Aitchison the Natives regard the galls as of no use, but value highly the leaves for dyeing and tanning purposes.

P. Terebinthus, Linn. The Terebinth Tree. A tree or shrub, common on the islands and shores of the Mediterranean. It yields a resin (Chian Turpentine), the *terebinth* of the ancients, produced chiefly in the island of Scio, where it is collected from incisions made in the stem and branches. [Cf. Holmes, *l.c.* 29; Tschirch, *l.c.* i. 482-3; *Kew Bull.*, 1903, 19-20; *Kew Mus. Guide*, 1907, No. 1, 54.]

P. vera, Linn. The Pistachio Nut; tree and nut = *pista*; galls = *bōz-għanj*; gum-resin = *kunjad*, *wanjad*, *kandur*, *shilm*, etc. A small tree, forming forests at 3,000 feet and upwards, in Syria, Damascus, Mesopotamia, Terek, Orfa, the Badghis and Khorasan; extensively cultivated in Syria, Palestine and Persia.

It yields a resin similar to mastic. The leaves are frequently affected by galls, irregularly spheroid in shape, borne on a short stalk and usually growing from the surface of the leaf. These, with the pericarp of the fruit and the unfertilised ovaries, are used locally for dyeing silk, and are exported to Persia, Turkestan and India. The fruit, known as the pistachio nut, is oval-shaped and varies in size with the amount of cultivation the tree has received. They are exported in large quantities from Afghanistan to India, Persia and Turkestan. In India the nut is a common article of food among the well-to-do classes, being fried with a little butter and salt and brought to the table hot. The nut is also a frequent ingredient of confectionery and ice-cream. It contains about 60 per cent. of a fatty oil which is occasionally extracted for use in medicine. [Cf. Aitchison, *Notes on Prod. of W. Afghanistan and N.E. Persia*, 1890, 156-9; *Pharmacog. Ind.*, i., 379-81; Holmes, *l.c.* 30; *Agri. Ledg.*, 1902, No. 1, 21; Firminger, *Man. Gard. Ind.* (ed. Field Pea.

Fodder.

PI U, Linn.; *Fl. Br. Ind.*, ii., 181; Prain, *Beng. Plants*, i., 368-9; Duthie, *Fl. Upper Gang. Plain*, 1903, i., 261-2; Cooke, *Fl. Pres. Bomb.*, 1903, i., 409; LEGUMINOSÆ. This genus comprises the grey or field pea and the common garden pea, both largely cultivated throughout India.

P. arvense, Linn.; Duthie and Fuller, *Field and Garden Crops*, ii., 17-8, t. xxxii. B. The Grey or Field Pea, *matlar*, *matlar rewari*, *kulon*, *keiao*, *korani*, *kulāwan*, *karain*, *ghāle*, etc. According to De Candolle, this pea is wild in Italy. It is extensively cultivated in many parts of India, during the cold weather, in the same way as **P. sativum**, under which details of the method will be given. It produces a small, round, compressed, greenish and marbled seed, generally eaten as *dāl* by the natives. It must be carefully distinguished from *khesāri dāl* (*Lathyrus sativus*, p. 703), which it somewhat resembles. The straw is a valued FODDER.

THE GARDEN PEA

PI U
ATIVU
Cultivation

P. sativu, Linn.; Duthie and Fuller, l.c. ii., 17-8, t. xxxii. A. The Garden Pea, *bara-mattar*, *bahtahna*, *kuda*, *shánma*, *ahandil*, *kalon*, *ahsa*, *sen*, *khandú*, *lár-kána*, *pattaníe*, *gundúsani-ghelú*, *pai*, etc. A more robust plant than the former, compared with which it is more valuable and prolific though a less hardy crop. It is not known anywhere as a wild plant, and is regarded by some as merely a variety or sub-species of *P. arvense*.

The field and garden peas are generally considered together by writers on Indian crops, and the methods of cultivation explained as applying equally to both. In all parts of the country the pea is a *rabi* crop. According to Woodrow (*Gard. in Ind.*, 1903, 263-6), the varieties of the white form may be sown at any time between May and January, if the rainfall is not over 40 inches. A rich, deeply cultivated soil that has been heavily manured for a previous crop and contains at least 5 per cent. lime is necessary for a good outturn. The area in Bombay for 1905-6 was 15,636 acres. As a field crop peas are sown in moist land in October or November, and receive, as a rule, no manure or irrigation. The crop is reaped at the end of February and March. Leaves and stalks are much valued as fodder, under the name of *halim*. In Cuttack, Bengal, Banerjee (*Agri. Cuttack*, 1893, 83) states that peas grow well on loose sandy soil after maize. The maize crop is removed about the middle of August, and the land ploughed twice or thrice between 15th August and 15th September. By the 15th September the land is manured with cow-dung at the rate of twenty-five cartloads to an acre, and then laid out in ridges and furrows at intervals of one foot. The seed is sown by hand, at the bottom of the furrows, then covered over, and the field watered every evening till the plants appear, six or eight days afterwards. Watering is continued for two months more, at intervals of about six days. About a fortnight after sowing, bamboo twigs are fixed into the ground for the plants to climb on. Weeding is necessary once a month. Flowering commences about the 15th October, and the pods begin to form in the middle of November. By the middle of February the pods are dry and ready for harvesting. In the United Provinces, Duthie and Fuller write that both species of pea are largely grown in certain districts. They are not returned as a separate crop, but together with *masur* (*Lens esculenta*, p. 708) occupied in 1904-5 an area of 2,055,879 acres. They are sown from the end of September to the middle of October, and reaped in March. In the western and central districts peas are most commonly grown as a second crop after indigo or rice. As a rule they are sown on very heavy soil, which receives little if any preparation and is rarely manured. The seed is sown broadcast at the rate of $1\frac{1}{2}$ to 1 maund per acre, and ploughed in. In the Oudh and Benares Division the crop is watered once; in other localities it is not always irrigated. The cost of production per acre is estimated at Rs. 12-13a. for the coarse kind with no irrigation, Rs. 17-13a. for the fine kind, assuming that two waterings are given and the land is of higher rent. For the year ending 1902 the average outturn of peas for the province was calculated at 1,150 lb. per acre irrigated, and 600 lb. per acre unirrigated. Cultivation in the Central Provinces closely resembles that in the United Provinces, but the crop is never irrigated. The area in 1904-5 was 247,779 acres; in Berar, 10,257 acres. In the Panjáb, peas are cultivated as a field crop almost entirely for fodder. Seed is sown on *sailáb* lands in October and November after a couple of ploughings. It may be sown broadcast on the same sort of soil, if too moist to plough. The seed-rate is 20 to 30 seers per acre. The crop is pulled, not reaped, in April, and the yield is 3 to 8 maunds seed per acre.

Uses.—The green pods are collected in many localities while the plant is growing, and are either cooked and eaten like French beans, or the young seed is extracted and eaten in the same way by Europeans. The roasted green pods are known in the Panjáb under the name of *dádhrián* and *ámíán*. The ripe seed is also used whole, split as *dál*, or ground and made into bread. In Burma peas are employed in the preparation of vinegar (p. 1111). The green plant and also the "straw" are extensively used and valued as FODDER, more especially in the P jáb and Bombay where they are regarded equal to hay. [Cf. De Candolle, *Orig. Cult. Plants*, 1882, 327-8; Bentham, *Rev. of Targioni-Tozzetti*, in *Journ. Hort. Soc.*, 1855, ix., 138; Asa Gray, *Scient. Papers*, 1889, i., 347; Leather, in *Agri. D. P., **POD PHYLLUM** **ODI, Wall.; Fl. Br. Ind., i., 112-3;**
vi., pt. i., **BERBERIDEÆ.** May Apple, Duck's Foot, American Mandrake, *pápura*,
9 -30 . *bhavan-bakra, ban-kakri, chimyáka, wan-wárgan,* etc. A small, erect,
American herbaceous plant, met with in the higher rich and shady temperate forests
andrake. from Sikkim to Simla, Kashmir, Hazara, Tibet, the Kuram Valley and
 Afghanistan.

Resin. Is closely allied to the American species *P. peltatum*, the source of the resin
 of *Podophyllum* of the British Pharmacopœia. The resinous constituent,
 known as *podophyllin*, was first prepared from the Indian root from specimens
 collected by me at Kullu and sent to the late Dr. Dymock at Bombay in 1888.
Prepara- The process adopted was that recommended in the British Pharmacopœia, which
tion. consists in exhausting the drug by percolation with alcohol, concentrating the
 percolate and precipitating the resin by adding water. Podophyllin thus ob-
 tained is an amorphous powder of a bright brown-yellow colour, if procured
 from the American species, but much lighter in colour, if from the Indian.
Action. The active portion—*podophyllotoxin*—consists of an amorphous principle soluble in
 alcohol, and isolated from a chloroformic extract of the root. Although the
 chemistry of the American species has been fully investigated, little had been
 done in that direction with the Indian plant till a few years ago, when specimens
 were sent by the Reporter on Economic Products to the Imperial Institute for
 examination. At the same time the therapeutic and physiological action of the
 Indian drug were investigated by Dr. H. G. Mackenzie and Mr. W. Dixon of
 St. Thomas' Hospital. The results of these inquiries proved that the chemical
 constituents of both the American and Indian drugs were identical and that
 the podophyllin prepared from the Indian species is as valuable a purgative as
 that obtained from *P. peltatum*. Bhaduri (*Rept. Labor. Ind. Mus.*, 1902-3, 28)
 found the Indian resinoid prepared at the Calcutta Medical Stores to contain
 35.7 podophyllotoxin. The Indian drug, moreover, was found to furnish a
 larger proportion of podophyllin than the American, and to be consequently
 of greater value as a source of the resin. It is thus highly desirable that a regular
 trade in the Native drug should be established. The commercial value of po-
 dophyllin is subject to considerable fluctuation, but is generally stated to vary
 from 7s. 6d. to 10s. a pound in wholesale quantities. The root also contains
Value. a valuable dye-stuff, *quercetin*, which is easy to isolate. Dunstan states that
 the separation of the dye as a by-product of the manufacture of podophyllin
 would probably repay the Indian producer. [*Cf. Pharmacog. Ind.*, i., 69-70;

vi., pt. i., **Rar.** i., 31; *P. Patchouli*, Hook., f., *Fl. Br. Ind.*, iv., 633; LABIATÆ.
7- . Indian Patchouli, *pehohi, pachôli, pachápdt, panel, mahi, pachpanadi,*
Indian *poko nilam,* etc. A plant found both wild and cultivated in Western and
Patchouli. Central India from Bombay and Berar southwards, and said to be the
 chief source of the Indian patchouli. The plant which affords the greater
 part of the patchouli perfume of European commerce is, however, *P.*
suave, Tenore (considered by Hooker a variety of *P. Patchouli*),
 which does not appear to be met with in India at all, but to be a cultivated
 form of *P. Cablin*, Benth., a native of the Philippines. [*Cf. Kew Bull.*,
 1908, 81.]

Perf e. Genuine patchouli (i.e. *P. suave*) is cultivated chiefly in the Straits Settle-
 ments and Penang. The patchouli of Assam is obtained from *Microtena cymosa*,
 Prain. In the Central Provinces and Berar I found *P. cyneanus* growing

THE APRICOT

in the *betel*-leaf houses and sold apparently by the owners to the perfume manufacturers. This may be, at least partly, the patchouli of Bombay. Gildemeister and Hoffmann, at all events, speak of the drug being shipped from both Calcutta and Bombay, but of poor quality. From the differences in chemical composition they suspect that the Calcutta herb is the Assam plant (*M. cymosa*). The Bombay plant, as suggested, may be derived from the *pan*-house cultivation, but in that case the supply must be very limited indeed. On the Girnar hills, Kathiawar, I was shown a plant (? *Strobilanthes iziocephalus*, Benth.) the large sticky and sweetly scented buds of which were being collected to be sent to Bombay as a perfume (? patchouli substitute).

The following is the method of patchouli cultivation pursued in the Straits. The soil most suitable is a stiff clay with a small percentage of silica. The land is trenched, the plants deposited in rows, 2 feet apart (during the wet season), and carefully shaded till the first crop is obtained. Two other crops are secured at intervals of six months, after which the plants are dug up and the land retrenched and manured. The crop is gathered by cutting down all but one stalk on each root, and placed to dry in the sun during the day and under cover at night. The dried stems are then made up into bales and sold. Adulteration with the leaves of *ruku* (*Ocimum Basilicum*, Linn., var. *pilosum*) or with those of *perpulut* (*Urena lobata*) is said to be common. The oil is prepared by passing steam through the leaves in a large copper cylinder and condensing the distillate. One *pikul* (133½ lb.) of the raw material yields from 24 to 30 oz. of the oil, and if free from the heavier stalks, about double that amount. The oil is very largely used in European perfumery. [Cf. Sawyer, *Odorography*, 1892, 293-308; *Kew Bull.*, 1897, 65; Gildemeister and Hoffmann, *Volatile Oils*, 1900, 656-8; Thorpe, *Dict. Appl. Chem.*, 1900, iii., 123; Schimmel & Co., *Semi-Ann. Rept.*, Oct.-Nov. 1905, 52; April-May 1906, 49-50.]

P U U, Linn.; *Fl. Br. Ind.*, ii., 312-7; Gamble, *Man. Ind.*, D.E.P., *Timbs.*, 1902, 311-5; ROSACEÆ. A genus which contains some 21 species within the Indian limits, including the almond, peach, apricot, plum and cherry. vi., pt. i., 34-51.

P. A ygdalus, Stokes. The Almond, *bádám*, *biláti-bádám*, *vádám-kottai*, *bádám-vitulu*, etc. A moderate-sized tree, indigenous in Western Asia and occasionally cultivated in Kashmir and the Panjáb. Almond.

There are two varieties, bitter and sweet, but these cannot be distinguished botanically. The almond yields a GUM, the *badám* or *Hog-tragacanth*, which is exported from Persia to Bombay and re-exported to Europe, while from the fruit are obtained two OILS, an essential and a fixed. The fixed oil is procured by expression from the seeds of both varieties. It is clear, yellow, with an agreeable flavour and is much used by perfumers, though frequently adulterated with gingelly, poppy or mustard oils. The essential oil is got from the bitter variety and is known as "oil of bitter almonds," but according to Gildemeister and Hoffmann, "only a very small amount of the bitter-almond oil of commerce is prepared from bitter almonds. For the manufacture of the oil, the seeds of the apricot (*P. armeniaca*) serve almost exclusively, and the oil thus prepared does not appear to differ in any respect from the oil obtained from bitter almonds." It is produced by submitting bitter-almond or apricot cake, left after expression of the fixed oil, to distillation with water, alone or mixed with salt. MEDICINALLY the almond has been used in Europe for many centuries, but is little esteemed in India. The kernels of the sweet variety are largely used in dessert and confectionery. [Cf. Benthams, *Rev. of Targioni-Tozzetti*, in *Journ. Hort. Soc.*, 1855, ix., 162; *Pharmacog. Ind.*, i., 563-7; Gildemeister and Hoffmann, *Volatile Oils*, 1900, 436-42.]

. ar eniaca, Linn. The Apricot, *Mishmus*, or "Moon of the Faithful," *chiári*, *zardalu*, *khúbani*, *pating*, *kushm-áru*, *gádam*, *iser*, *cherkúsh*, *hári*, *shíran*, *mandata*, *nakhter*, etc. A moderate-sized deciduous tree, cultivated in the Western Himalaya, hardly ever ripening its fruit on the eastern section. Roxburgh and De Candolle, however, consider China its original home. Stein (*Ancient Khotan*, 1907, 131, 337, etc.) says that the labourers employed by him, in his excavations, identified the wood found in the houses, as also in the remains of orchards, being the *úrúk* (the apricot)—a plant with which they were fully conversant. This would fix its cultivation in ancient Khotan at least prior Apricot.

THE PEACH AND NECTARINE

to the closing decades of the 8th century—the date at which the last of the series of cities was abandoned and enveloped in sand.

The apricot yields a GUM similar to tragacanth, known commercially as *Cherry-gum*. A clear OIL is extracted from the seed and used in burning, cooking, and for the hair. As already explained, from the cake is obtained the bitter-almond oil of commerce. The seeds are brought from Asia Minor into Europe as "peach kernels." The fruit ripens from May to September, according to elevation. In the North-West Himalaya dried apricot forms a considerable portion of the FOOD of the people, but the fruit is also eaten fresh. By Europeans it is largely employed in this state for making jam, and when dried for cooking. The dried fruit is also an important article of trade, being brought to the plains of India from Afghanistan and the neighbouring hills. The emporium of this trade is Leh, where, according to a writer in *Capital* (Oct. 19, 1905), about 300 maunds are imported annually from Baltistan or Little Tibet. The same writer states that in the Afghanistan *khubanis* the trade is in the hands of Kabulis, who retail the moist stoneless fruits in the Calcutta market at 8 annas to 1 rupee per seer, and the dried fruit at about Rs. 1-8 per seer. Gamble states that the wood is handsome and used in the Panjáb for various purposes, while in Lahoul and Upper Kunawar it is the chief firewood. [*Cf.* Hoffmeister, *Travels in Ind.*, 1848, 392-3, 464; Bentham, *l.c.* 163; Smythies, in *Agri. Ledg.*, 1894, No. 15, 5-6, 45-6; *Ind. For.*, 1895, xxi., 70-2; *Ind. Gard.*, May 18, 1899, 205; Gildemeister and Hoffmann, *l.c.* 437; Firminger, *l.c.* 245; Sly, *Fruit in the N.W. Front. Prov.*, in *Agri. Journ. Ind.*, i., pt. iii., 268-9.]

Dwarf Cherry. *P. Cerasus*, Linn. The Sour or Dwarf Cherry, *alu-bálu*, *gilás*, *olchi*, *jerasayna*, etc. According to De Candolle, this is a native of the region stretching from the Caspian Sea to Western Anatolia. In India it is cultivated in the Panjáb Himalaya and North-West Provinces, up to 8,000 feet. It yields a GUM similar to tragacanth. In Europe the kernel is used for flavouring several liqueurs and the fruit for making preserves, while the wood is valued by cabinet, musical instrument and pipe makers. [*Cf.* Bentham, *l.c.* 160; Smythies, in *Agri. Ledg.*, *l.c.* 42, 46-54; Firminger, *l.c.* 246-7.]

Plum. *P. co unis*, Huds., var. *institia*. The Plum, *alucha*; fruit = *áli*, *khárâ*, *alubukhára*, *alecha*, *bhotiya badám*, *olchi*, *er*, *gardalu*, *luni*, *alpogádd-pazham*, etc. A moderate-sized tree, cultivated (or indigenous) in the Western Himalaya from Garhwal to Kashmir, at 5,000 to 7,000 feet. It yields a yellow GUM of little value, which somewhat resembles gum-arabic. An OIL prepared from the kernels, the "Plum-oil" of Europe, is used for illuminating purposes. The ripe fruit is eaten by all classes and is much esteemed. In a dried condition, a variety, the Bokhara plum, is imported in quantities from Afghanistan, and is much used as an article of diet. It also forms an ingredient of a common *chutni*. The true plum (var. *domestica*) is cultivated to a small extent in the plains of Northern India, but the fruit is inferior to that produced on the hills. Gamble states that the wood is smooth to work and is used in Kashmir for the fra ework of the so-called papier-maché boxes. [*Cf.* Bentham, *l.c.* 161; Smythies, in *Agri. Ledg.*, *l.c.* 42, 46; Woodrow, *Gard. in Ind.*, 1903, 306; Firminger, *l.c.* 245-6.]

ird Cherry. *P. adus*, Linn. The Bird Cherry, *jamana*, *likh-ar-u*, *hlo sa*, *hlot-kúng*, *bombaksing*, *zamb-chule*, *páras*, *kálakút*, *gidar-dák*, *bart*, *zúm*, etc. A moderate-sized deciduous tree of the Himalaya from the Indus and Kuram Valley to Sikkim, at 6,000 to 10,000 feet (Gamble). It yields an inferior GUM and a poisonous OIL, which may be used MEDICINALLY. The fruit is eaten by the Natives and the leaves form an excellent cattle FODDER. The wood is occasionally used for making railings, agricultural implements and spoons.

D. P., iii., 449. Peach and Nectarine. *P. persica*, Stokes. The Peach and Nectarine, *aru*, *takpo*, *rek*, *súnnú*, *chinnánú*, *bem beimi*, *mandata*, *shaftalu*, *ghwareshtai*, etc. A small tree, native of China, cultivated all over India, especially on the eastern side, and often found running wild. The tree flowers, according to elevation, from January to May, and the fruit ripens between May and October. For the method of propagation the reader should consult Smythies and Firminger. Like other species of *Prunus*, it yields small quantities of unimportant GUM. From the kernels an OIL is obtained, used by the Natives of the North-West Himalaya for cookery, illuminating purposes, and as a dressing for the hair. [*Cf.* García de Orta, 1563, *Coll.*, xvi.; Bentham, *l.c.* 163; Smythies, in *Agri. Ledg.*, *l.c.* 17-8, 42, 46; Woodrow, *Gard. in Ind.*, 1903, 303-6; Firminger, *l.c.* 242-4.]

P. Puddu, Roxb. Wild Himalayan Cherry, *paddam*, *kongki*, *pūya*, *chamīari*, *amalguich*, *padma-kasta*, etc. A moderate-sized (in Sikkim a large) deciduous tree, wild in the Himalaya from the Indus to Assam, between 2,500 and 7,000 feet; Khasia hills; hills of Upper Burma; often cultivated. It yields an abundant GUM, which is not made use of, and the kernels contain an OIL similar to that of bitter almonds. The fruit is little eaten by Natives, but is sold in quantities to Europeans for the manufacture of hill cherry brandy. According to Kanjilal, the stones are made into rosaries and necklaces by fakirs. The wood is used in the Panjáb Himalaya for walking-sticks (made of saplings, or root-suckers), and in Darjeeling is worked up into furniture. [*Cf. The Bower Manuscript* (Hoernle, transl.), 1893-7, 102, 104, etc.]

P IDIUM GUYAVA, Linn.; *Fl. Br. Ind.*, ii., 468; Talbot, *List Trees*, etc., 1902, 166; Gamble, *Man. Ind. Timbs.*, 1902, 355; Prain, *Beng. Plants*, 1903, i., 487; Cooke, *Fl. Pres. Bomb.*, 1903, i., 498; MYRTACEÆ. The Guava, *amrūt*, *peyara*, *madhuriyam*, *amuk*, *gaya*, *anjir*, *zard*, *perala*, *jambá*, *guava*, *segapu*, *cova*, *sebe*, *pela*, *málaká beng*, etc. A small evergreen tree, introduced from America and now cultivated and found semi-wild all over India.

D.E.P.,
vi., pt. i.,
351-3.
Guava.

It is grown solely for its fruit. According to Firminger, the best qualities are produced in Allahabad and its neighbourhood. Young plants are easily raised from seed during the rains, but propagation by layers is usually resorted to, and rooted suckers may also be taken from the base of the main stem. It requires no particular cultivation and thrives in any soil. The tree blossoms during the hot season and continues to do so and to bear fruit to the end of the cold season. The finest fruit, however, is said to be obtained when the general bearing season is over. There are two varieties, one known as the Pear Guava, the other as the Apple Guava, but they are so alike that they can scarcely be distinguished till cut open. The fruit is eaten by all classes, but by Europeans is generally preferred stewed or in the form of jelly or of the well-known "Guava cheese." According to Gamble, the wood is made into spear-handles and special instruments. In Vellore, North Arcot, it is said to be used for lac-turnery. In Assam, the leaves and bark are employed in DYEING, and in Bengal and the United Provinces are occasionally employed in TANNING. [*Cf. Merian, Insect. Surinam*, 1705, tt. 19, 57; *Pharmacog. Ind.*, 1891, ii., 30-2; Duncan, *Monog. Dyes and Dyeing, Assam*, 1896, 41; *Agri. Ledg.*, 1901, No. 9, 346; 1902, No. 1, 43; Firminger, *Man. Gard. Ind.*, 1904, 235-6.]

T CARPU, Linn.; *Fl. Br. Ind.*, 238-9; Prain, in *Journ. As. Soc. Beng.*, 1898, lxvi., 123-4; also in *Ind. For.*, 1900, xxvi., app.; Gamble, *Man. Ind. Timbs.*, 1902, 257-62; Prain, *Beng. Plants*, 1903, i., 411-2; Brandis, *Ind. Trees*, 1906, 239-40; LEGUMINOSÆ. A genus of great economic importance, including the trees which yield Gum-kino, Red Sanders, Andaman Redwood and *Padouk*.

D. P.,
vi., pt. i.,
355-6.

. dalbergioides, Roxb.; *P. indicus*, *Fl. Br. Ind.*, ii., 238 (in part). Andaman Redwood or *padouk*, *chalanga-dá* of the Andamans. A large tree sparingly cultivated in Bengal and Southern India. It has frequently been confused with the next species, a Burman plant also known by the name of *padouk*.

Padouk.
Anda n.

In the Andaman Islands this "is the principal timber tree and its wood has of recent years obtained a good place in the markets of Europe and America as a handsome wood for furniture, parquet floors, railway carriages, door-frames and balustrades, etc. In India it has long been in use as a gun-carriage wood, and stores are kept in the arsenals of Calcutta, Madras and the Kidderpore Dockyards" (Gamble). Recently it has been successfully employed in England in panelling, and in America in the building of Pullman cars. [*Cf. For. Admin. Repts. Andaman Islands*; Todd, *Rept. Explor. N. Andamans*, 1905; Anderson, *Rept. Explor. N. Andamans*, 1905; Gilbert Rogers, *Rept. Dept. Conservator of For., Andaman Islands*; *Ind. For.*, 1905, xxxi., 511-7; also Todd, 1906, x ii., 581-7.]

Timber.

. indicus, Willd.; *Fl. Br. Ind.*, ii., 238 (in part). A deciduous tree believed to be indigenous in the Malay Peninsula and Archipelago; cultivated in Moul-

mein, Amherst and Tavoy. This is the species hitherto supposed to be the source or a source of the wood known generally as *padouk* of Burma, and with which the previous species, *P. dalbergioides*, was, till Prain studied these trees, commonly confused. The circumstances that led up to this are fully discussed by him (*Ind. For.*, l.c. 6). It seems certain that the name *padouk* is not applied to *P. indicus*, and possibly that *P. indicus* is not an indigenous species anywhere in Burma. [Cf. Greshoff, in *Nutt. Ind. Pl.*, in *Kolon. Mus.*, Amsterdam, *Extra Bull.*, 1896, 107.]

urma
Padouk. *P. acrocarpus*, Kurz. Burma *padouk* or simply *padouk*. A deciduous tree of the *eng* and upper mixed forests of Burma; Shan, Chin and Karen hills of Upper Burma, Pegu and Martaban. According to Prain, this species alone is entitled to the name Burma *padouk*. Gamble states that the wood is harder and heavier than that of *P. dalbergioides*, but, though a fine handsome wood, is probably not used outside Burma.

Gum-kino. *arsuplu*, Roxb.; Hooper, in *Agri. Ledg.*, 1901, No. 11. The Indian Kino Tree, *bija*, *bijasal*, *piasāl*, *hitin*, *murga*, *pedei*, *radat bera*, *dhorebula*, *bibla*, *hūni*, *houne*, *āsan*, *vengai*, *pedegu*, *peddagi*, *benga*, *karinthagara*, etc.; the gum = *hīrā-dokhi*, *nāt-kā-dammul-akhvān*, *kāndāmīruga-mīrattam*, *vēnnap pasha*, etc. A large deciduous tree of Central and South India and Ceylon, extending northwards as far as the hills of Bihar, Binda and the Kumaon Terai.

Chief Supply. This species yields the *gum-kino* of European *Materia Medica*. To E. M. Holmes is due the credit of having originated the modern interest taken in Indian *kino*. In a letter, September 23, 1895, he drew my attention to the high prices then ruling in Europe for the extract. He recommended that the Indian production should be investigated and an improved supply cautiously introduced. In consequence an inquiry was instituted all over India, and the information thus brought together was published by Hooper. The manufacture of *kino* from the juice of *P. Marsipium* is conducted in the district of North Malabar. The best season for collecting is the dry weather during February and March, when the trees are in blossom. The right to tap the trees is put up to auction. In other cases, the tapping is conducted by rangers under the supervision of the district forest officers. The following is the method of collecting adopted a few years ago by Mr. J. G. F. Marshall, the District Forest Officer. A longitudinal cut is made with an axe or knife (*macha katti*) through the bark of the tree down to the cambium, about 1½ feet long, and side cuts are made to lead into this. A bamboo tube is then fixed at the bottom of the main incision to catch the juice. In about twenty-four hours the flow of gum ceases and the bamboo is taken down. When several of these bamboo tubes are nearly full, they are carried to headquarters and emptied into a large cauldron and boiled. During the boiling, the impurities which rise to the surface are skimmed off. When sufficiently concentrated it is exposed to the sun in shallow vessels till dry enough to crumble to pieces. It is then weighed and packed away in boxes. Another method, more recently adopted in North Malabar, is to dry the juice in shallow trays in the shade. The trays are arranged on tiers or shelves in a shelter constructed of bamboo, and the dust excluded by muslin-covered doors. The gum is poured into the trays in layers about one-eighth of an inch thick, and takes about seven or eight days to dry, producing a dark ruby *kino* of great purity. Marshall found the yield to be about 1½ lb. of juice per tree, equivalent to ¾ lb. of the dried gum, ready for medicinal purposes. The yield of dry *kino* from the liquid exudation depends on the consistence at the time of collection, but is usually 50 per cent. E. White has recently pointed out that the peculiar insolubility of Malabar *kino* in alcoholic and aqueous solutions is due to the action of an enzyme. From this Hooper infers that commercial *kino* is improved by boiling before evaporation to dryness (*Rept. Labor. Ind. Mus.*, 1903-4, 31).

Method of Collection.

Boiling.

Drying in Shade.

Yield.

Enzymic Action.

Production. In North Malabar alone, it is stated that about 2,000 pounds of *kino* can be procured annually, at the price of 3 to 4 annas a pound, but there is scarcely any demand for the article in India except by the Medical Store Departments of Calcutta, Madras and Bombay. In addition to its medicinal use it is said that *kino* is also employed at a certain stage in the preparation of some wines. The drug collected in Malabar finds an outlet in the ports of Calicut and Tellicherry. The Native State of Travancore exports its produce through Cochin and Alleppey, while gum collected in South Kanara is despatched from Mangalore. Much of the *kino* is known as *Cochin grain*, probably because Cochin is the principal port of call. Gamble says "there is a considerable demand for *kino* gum

Trade.

Cochin Grain.

for export, much of it going to France." In 1897-8 the price for genuine "Cochin" grain was 10s. per lb.; in 1899 the price fell during the year from 10s. to 2s. per lb., and in 1900 it is said to have been sold at 1s. per lb. In a report by Dunstan, of September 1905, the market price in London is stated to be 4d. per lb. Recently the drug has been examined with a view to discover its value as a tanning material, and a report (*Kino as Tanning Mat., Imp. Inst. Rept., Sept. 13, 1905*) was issued on the results obtained. Dunstan considers that *kino* would be quite suitable for use as a tanning material, on a commercial scale, provided it could be obtained at a sufficiently low cost to enable it to compete with other tanning materials. He regards a price of about 2d. per lb. as the limit. Experiment seems to prove that the *kino* prepared by the method of merely drying the juice in the sun is the best for use as a tan.

Tanning
Material.

The bark is occasionally employed for DYEING. Sir Thomas Wardle found it to contain a brownish-red colouring matter, which produced reddish-fawn colours with tasar silk. In the territory of Goa it is also employed for its astringent properties. The leaves make an excellent FODDER, and are reported by Mollison to be specially valuable as a MANURE. After teak and blackwood, the *kino* WOOD is said to be the most important in South India, and to be in great demand for door and window frames, posts and beams, furniture, agricultural implements, cart and boat building, and has also been used for sleepers. It has a high reputation in the manufacture of double-headed drums, being regarded as specially sonorous. [Cf. *Pharmacog. Ind., i., 464-7*; Schaer-Strassburg, *Drachenblut und Kino*, Reprint from *Proc. Germ. Pharm. Soc., 1901*; *West African Kino*, in *Der Tropenpflanzer., June 1902, vi., 305-8*; *Imp. Inst. Tech. Repts., 1903, 175-6*.]

P. santalinus, Linn., f. Red Sanders Tree, Red Sandal-wood, *rukhto-chandan, undum, tilaparni, ranjana, ratanjli, tãmbada, chandana, shen-shandanam, erragandhapu-chekka, gandham, rempugandha-cheke, sandaku*, etc. A small tree of South India, chiefly in Cuddapah, North Arcot and the southern portion of the Karnul district. On a small area, near Kodur, in Cuddapah, it has been very successfully cultivated (see p. 976).

Red
sanders
Wood.

In former years the great use of the wood of this species was as a DYE, and large shipments were made annually from Madras to Europe, where it was employed as a colouring agent in pharmacy, for dyeing leather and for staining wood. The demand, however, has now greatly declined, due probably to the increase in the use of artificial dyes. In India it is chiefly employed in marking idols and for staining the forehead in certain caste markings. The value of the wood as a dye is due to a red colouring principle, *Santalin*, soluble in alcohol and ether, but not in water. When dissolved in alcohol, it dyes cloth a beautiful salmon-pink.

Dye.

Caste Markings.

The Wood is highly prized for house posts, and in the South Deccan is universally employed for plough-poles and other agricultural implements. It is also in great demand for carved work, wood idols, boxes and picture frames. [Cf. Garcia de Orta, 1563, *Coll., xlix.*; *Pharmacog. Ind., i., 462-4*; Hadi, *Monog. Dyes and Dyeing in U. Prov., 1896, 81*; Holder, *Monog. Dyes and Dyeing in Madras, 1896, 4*; Dutt, *Mat. Med. Hind., 1900, 154*; *For. Admin. Repts. Madras*; Hanausek, *Micro. Tech. Prod. vi., pt. i.,
3 8-7 .
Po e-
ranate.

In many parts of India and Burma it is cultivated for its fruit, which, however, according to Firminger, is not to be compared with that brought down annually by Afghan traders from Kabul. It is not particular as to soil, is said to succeed even in the driest, but does not thrive in very damp climates. To yield good fruit, it must be manured every year, preferably in December. Plants may be multiplied either by seed, by cuttings, or by layers. The best method is to raise seedlings and graft on them, when of sufficient height, from trees of a superior kind. It bears fruit principally during the cold season. Before the fruit is a quarter grown, it is frequently penetrated by a caterpillar which devours the interior and causes the remainder to rot. To prevent this, when still

small, it should have the calyx cut clean off and then be tied up loosely in a piece of linen cloth. When ripe it is about as large as a full-sized apple, with a hard rind of a brownish-red colour. The quality varies in different localities. In the Lower Provinces and Bengal it is inferior to that of the North-West and hilly regions. By the Natives, a cooling sherbet is made of the pulp, and from remote times it has been valued for its MEDICINAL properties.

In various parts of India the flowers are used as a red DYE, while the astringent rind of the fruit and the bark are valuable TANNING materials. The Wood is not used for any purpose, but according to Gamble might be substituted for boxwood. [Cf. Merian, *Insect. Surinam*, 1705, tt. 9 and 49; *Pharmacog. Ind.*, 1891, ii., 44; Cameron, *For. Trees of Mysore and Coorg*, 1894, 150-1; *Monographs, Dyes and Dyeing* :—Duncan, *Assam*, 1896, 42; Hadi, *U. Prov.*, 1896, 80; Fawcett, *Bomb. Pres.*, 1896, 34; Russell, *Cent. Prov.*, 1896, 14-5; *Agri. Ledg.*, 1902, No. 1, 43-4; Woodrow, *Gard. in Ind.*, 1903, 319-20; Firminger, *Man. Gard. Ind.*, 1904, 234-5.]

PY U, Linn.; *Fl. Br. Ind.*, ii., 372-80; Gamble, *Man. Ind. Timbs.*, 1902, 321-4; ROSACEÆ. A genus of moderate-sized trees, occurring in the Himalaya, Khasia hills and Burma. Several bear edible fruits, of which the best known are the apple and the pear. In this place may be mentioned the closely allied plant *Cydonia vulgaris*, Pers.—the *quince* or *bilû*—a small tree cultivated in the Western Himalaya.

. co unis, Linn. The Common Pear, *nashpâti*, *nak*, *kishta*, *bahira*, *tang*, *amrûd*, *charkeint*, *li*, etc. A small tree blieved to be wild in Kashmir, cultivated throughout the Himalaya, on the Nilgiris, at Bangalore and elsewhere in South India.

The pear-tree thrives well in most parts of India, and is easily propagated by layering or grafting. The latter operation should be performed in February or March. Cuttings will also strike root if put down in February during the rains. The fruit ripens about August or September; as a rule, the tree does not come into bearing before it is ten years old. A full account of the method of cultivation on the hills is given by a writer in *Indian Gardening* (Feb.-March 1899). The fruit of the ordinary hill-pear is generally hard and flavourless, and, though eaten by Natives, is little used by Europeans except for cooking purposes. In Kangra and the lower inner ranges of the Himalaya, pears from imported European stocks are grown to great perfection, and the produce is exported to the hill stations and the plains. In Europe the Wood is prized for engraving and turning, but especially for drawing implements, such as set-squares, etc. [Cf. Bentham, *Rev. of Targioni-Tozzetti*, in *Journ. Hort. Soc.*, 1855, ix., 158; Smythies, in *Agri. Ledg.*, 1894, No. 15, 5, 34-47; Coldstream, *Rept. on Fruit Cult. in Simla Dist. and Kullu*, 1894, 7, 14; Woodrow, *Gard. in Ind.*, 1903, 308; Firminger, *Man. Gard. Ind.*, 1904, 249-50.]

P. alus, Linn. The Apple, *seb*, *kûshû*, *sher*, *tsûnt*, *sûn*, *ching*, *li*, *pâlu*, *manra*, *sévu*, etc. A moderate-sized tree indigenous in Eastern Europe and possibly also in the Western Himalaya, between 5,000 and 9,000 feet; largely cultivated in the Himalaya, the Panjâb, Sind, North-West Provinces, Central India and the Deccan. Stein discovered apple-wood (*alma*) used in the house-construction of ancient Khotan (see the remark regarding the Apricot, p. 905).

In India, apple-trees are propagated by layering and grafting on the common country, or long acclimatised stock. Firminger, quoting General Jenkins, states that cuttings may be planted in January and February near water and also during the rains. When they shoot strongly they should be planted out and cut down to two or three buds, and of these the strongest shoot only should be allowed to grow. This should be trained straight up to a height of about three feet. Grafting takes place in March. A gravelly soil is most suitable. The best fruit is produced in the Kangra Valley, whence it is exported in quantities to Simla and the plains of India. The traffic from Kashmir to Rawalpindi and the Panjâb generally has become a large and important one. Government orchards have been established in Kumaon, where apples of choice English sorts are successfully grown. The Municipality of Simla has also made an effort to utilise as an orchard the tract of hills reserved as the catchment area in water supply. Sly (*Agri. Journ. Ind.*, 1907, ii., pt. i., 70-3) reviews the available information regarding the apple cultivation of the hills of India. In Afghanistan, he tells us,

the apple is raised from seed and is not grafted. Baber (*Memoires* (Leyden & Erskine, transl.), 281) mentions the apples of Kabul. In the Shan States (Burma) the apple is grafted on to *Docynia indica*. [Cf. Benthham, l.c. 159; Symthies, in *Agri. Ledg.*, l.c. 3-5, 45, 38-41; *Fruit Cult. on the Hills*, in *Ind. Gard.*, Dec. 1, 1898, to Feb. 16, 1899; Woodrow, l.c. 306-7; Firminger, l.c. 247-9.]

QU CU, *Linn.*; *Fl. Br. Ind.*, v., 600-19; Gamble, *Man. Ind. Timbs.*, 1902, 671; Prain, *Beng. Plants*, 1903, ii., 986-7; Brandis, *Ind. Trees*, 624-33; CUPULIFERÆ. A large genus of important forest trees attaining their greatest Indian development in the Eastern Himalaya, the Khasia hills and Manipur. Thirty-one species occur in India and Burma.

D.E.P.,
vi., pt. i.,
379-6.
Oaks.

. latata, *Lindl.* The Green Oak of the Himalaya, *moru*, *tilangsa*, *kilonj*, *ramshing*, *káli ring*, *chora*, *parúngá*, *bán*, *karsh zaih*, etc. A large, nearly deciduous tree of the inner Himalaya, extending westward to Afghanistan and the Safedkoh, eastward to Nepal, usually at 7,000 to 9,000 feet.

Green Oak.

According to Brandis, the wood is durable, and used for building, agricultural implements, axe-handles and jampan poles. Gamble states that in the Tons Valley Sleeper Works it is the best wood for making the runners of the sledges used in the extraction of the deodar timber. In the Simla district it is extensively used in the manufacture of charcoal. The leaves and shoots are also regularly lopped for fodder, and the bark has been tried for tanning. [Cf. Hooper, in *Agri. Ledg.*, 1902, No. 1, 55.]

Wood

Charcoal.

. incana, *Roxb.* The Grey Oak, *banj*, *sila*, *supári*, *rin*, *vari*, *máru*, *karshu*, *shindar*, *seret*, *daghúnbán*, etc. A large evergreen tree of the Himalaya from the Indus to Nepal at 2,000 to 8,000 feet; also the Shan hills, Burma.

Grey Oak.

According to Gamble, this is perhaps the best known of Indian oaks, and is one of the most common trees near the hill stations of Simla, Mussourie, Naini Tál, etc. The wood is little used for timber as it warps and splits badly, and is rarely straight, but it is occasionally employed in building and for agricultural implements. Its chief use is as fuel, both as firewood and charcoal. The bark yields a reddish-fawn colouring matter and is employed for tanning purposes. In 1894 Prof. Trimble examined the barks of various Indian oaks and found this one contained by far the largest quantity of tannin, viz., in the dry bark, 23.36 per cent. [Cf. *Agri. Ledg.*, l.c. 55.]

Wood.

Charcoal.

Tanning.

. la ellosa, *Smith.* The *shalshi*, *pharat-singhali*, *budgrat*, *búk*. A very large evergreen tree of the Eastern Himalaya from Nepal to the Daphla hills at 5,000 to 9,000 feet; Manipur at 7,000 to 8,000 feet. Is said to be the finest and most important tree of the Darjeeling forests, reaching occasionally 100 to 120 feet in height. The timber is durable, if not much exposed to wet, and is used for posts and beams in the construction of houses and bridges, for doorposts, window-frames and rafters. It is also an excellent fuel. In Darjeeling the bark is used for tanning. [Cf. *Agri. Ledg.*, l.c. 55.]

Wood.

. lusitanica, *Lam.*; *Q. insectoria*, *Oliver.* The Gall or Dyer's Oak, *najuphul*, *mazu*, *máya*, *machakái*, *pyintagar-rethi*, etc. A middle-sized tree or shrub, native of Greece, Asia Minor and Syria, extending to Persia, whence the galls are imported into India. These are excrescences caused by an insect puncturing the twigs and depositing its ova. They are extensively used both as a dye and medicine. In dyeing they are boiled in water till about three-fourths of the water is evaporated, and the cloth is then dipped in the decoction. Medicinally they are used either in the form of a powder or as an ointment. [Cf. *Pharmacog. Ind.*, 1893, iii., 360-4; Hadi, *Monog. Dyes and Dyeing*, U. Prov., 1896, 83.]

Oak Galls.

Dye and
Medicine.

. se ecarpifolia, *Smith.* Common Brown Oak of the Himalaya, *ghesi*, *karshu*, *khareu*, *b char*, *jangal ka parúngi*, *kreu*, *sauj*, etc. A large evergreen tree of the inner Himalaya extending westward to the Safedkoh and Afghanistan, eastward to Bhutan and the hills of Manipur, usually at 8,000 to 12,000 feet.

rown
Oak.

According to Gamble, the timber of this species is not in great demand, but is of good quality, strong and durable. It is an excellent firewood and yields charcoal of the best description. The leaves and young shoots are plucked for

Wood.

Charcoal.

Silkworm.

fodder and employed for litter. In spring the monkeys often do much injury to the tree by tearing down the topmost branches to get at the young shoots. The leaves have also been found suitable for feeding the Chinese silkworm (*Antheraea pernyi*, see p. 1005). [Cf. *Rev. For. Admin. Brit. Ind.*, 1897-8, 53.] A supply of living cocoons was procured in 1898 and distributed partly to Darjeeling and partly to Chakrata. Those sent to Darjeeling failed, but some 5,000 larvæ were hatched from the supply sent to Chakrata. They were fed at first on the *bán* oak, but did not flourish and were removed to Deoban, at an elevation of 8,000 feet, and finally fed on the *karshu* oak, on which they were much more successful. The bark yields tan, but in much smaller quantities than that of *Q. incana*. [Cf. *Ind. For.*, 1894, xx., 452-3; 1895, xxi., 149-51, 264-5.]

Radish.

APHANU ATIVU, *Linn.*; *Fl. Br. Ind.*, i., 166; Prain, *Beng. Plants*, i., 1903, 223; Duthie and Fuller, *Field and Garden Crops*, pt. iii., 14; Duthie, *Fl. Upper Gang. Plain*, 1903, i., 48; CRUCIFERÆ. The Radish, *múli*, *muro*, *mula sinki*, *tara mira*, *múnga*, *maguni-gadde*, *mullangi*, *bili*, *lobak*, etc. An annual herb, cultivated throughout the plains of India and in the Himalaya up to 10,000 feet. The Rat-tailed Radish (*R. caudatus*, *Linn.*), is commonly cultivated in Western India and the Panjáb.

Cultivation.

According to Roy (*Crops of Beng.*, 1906, 142-3), high and well-drained sandy loam is invariably chosen for radish cultivation. All through the rainy season and after, the land is frequently ploughed and thoroughly pulverised in preparation for this root crop. The seed is sown from the middle of August to the middle of November, 1 seer per acre, and the field is immediately harrowed. Cow-dung manure at the rate of 50 maunds per acre is applied directly after sowing. The crop is weeded and irrigated at intervals, and a month after sowing is ready for harvest. In many parts of the country it grows larger than an average good-sized carrot, and is eaten more as a vegetable than as a flavouring ingredient in salad. There are, in fact, several distinct cultivated races, the radish most common in Bengal being a long tapering root of a purplish rather than a scarlet tint. Roxburgh's description is admirable. "The root," he says, "grows to the size of a man's leg, or more, and is only half immersed in the soil." Duthie and Fuller allude to its value as a famine food, a crop being rapidly obtained on the climatic conditions proving favourable. The root is eaten both raw and boiled, and is occasionally pickled.

Seasons.

Races.

Food.

Oil.

The radish is cultivated not only for the root, but also for the young seed-pods and the leaves, all of which are eaten. The unripe pods (especially of the rat-tailed radish) are boiled and eaten with *ghi* or cooked in curries, and are also sometimes pickled. Both roots and seeds yield on distillation with water a small amount of a colourless sulphureous OIL heavier than water. This is used medicinally. A special form is in fact cultivated in Sylhet on account of the sweet oil obtained from its seeds (see *Daucus*, p. 491). [Cf. *Bentham, Rev. of Targioni-Tozzetti, Journ. Hort. Soc.*, 1855, ix., 146; *Pharmacog. Ind.*, i., 129; Basu, *Agri. Lohardaga*, 1890, pt. i., 77; Banerji, *Agri. Outlack*, 1893, 114-5; Dunstan, in *Agri. Rhubarb.

U I, *Wall.*; *Fl. Br. Ind.*, v., 56; POLYGONACEÆ. The Rhubarb, *Hindí-révand chini*, *dolu*, *padam-chal*, *chukri*, *archu*, *chutidí khabium*, *pambash*, *átsú*, *náttu-manjat-chinak-kishangu*, etc.

Found wild in the sub-alpine Himalaya of Nepal and Sikkim at altitud of 11,000 to 12,000 feet, and is usually considered to be the source of the so called Himalayan Rhubarb. Commercial rhubarb, known as *Chine* and *Eas Indian*, is said to be obtained from *. officinale* and *. palmatum*, which grow in South-East Tibet and North-West China. [Cf. *Prjevalski, Mongol*, 1870

ii., 81-6, and note to same by Sir H. Yule, 291-8.] Both Garcia de Orta and Linschoten state that rhubarb is brought from China (Tartary) through Persia and thence to India. The official part of the plant is the decorticated and dried root or root-stock. Himalayan rhubarb is usually stated to be of little commercial importance, and the rhubarb sold in the bazárs of the plains is ordinarily affirmed to be of an inferior grade to the Chinese drug, and still more to that imported from London. Considerable quantities are, however, annually conveyed to the plains from the Kangra district of the Panjáb. An inquiry in 1894 revealed the fact that the exports from that valley came to about 1,000 maunds a year. Further, it was stated to be largely used in the fabrication of certain external applications (*Pres. Add. Med. Congress, Calc., 7*). It is remarked in the *Pharmacopœia of India* that were the Himalayan rhubarb cultivated with due care, there is reason to believe a drug equal to the Chinese or Turkey rhubarb might be obtained. [*Cf. Paulus Ægineta* (Adams, transl. and Comment.), iii., 316; app., 478-80; *Mesua* (ed. Marinus), 1562, 50; Garcia de Orta, 1563, *Coll.*, xlviii.; Linschoten, *Voy. E. Ind.*, 1598 (ed. Hakl. 435; Gamble, *Man. Ind. Timbs.*, 1902, 332-3; Prain, *Beng. Plants*, i., 475; RHIZOPHOREÆ. The Mangrove, *khamo*, *bhora*, *râi*, *kunro*, *upu-poma*, *byu*, *bakan*, etc. A small evergreen tree of the muddy shores and tidal creeks of India, Burma and the Andaman Islands.

The BARK is exported from Mergui to Rangoon, and a considerable trade is also done in it from the Perak coast. It yields a DYE and TAN. Samples of bark of *R. mucronata* were sent to the Imperial Institute in 1899 (*Imp. Inst. Tech. Repts.*, 1903, 186-90), and were found to vary greatly in yield of tannin, one sample giving over 27 per cent., while another gave only 4 per cent. An extract, prepared presumably from the former sample, contained 76 per cent. tannin. In the *Report of Forest Administration in Burma* (1904-5, 19), mention is made of the establishment of a tannin factory in accordance with a system recommended by Dunstan. So far the extract thus prepared sold at less than it cost. For dyeing cotton, an extract was declared superior to that of other mangroves, but much inferior to the best qualities of cutch. The fruit is said to be sweet and edible, and a light wine is made from the juice. From the aerial roots, salt is occasionally extracted. The wood is reported to be good but rarely made use of. [*Cf. Ind. For.*, 1897, xxiii., 413; Hooper, in *Agri. Ledg.*, 1902, No. 1, 35-6; Grass, *Berichte über Land-und Forstwirtschaft in Deutsch Ost Afrika*, 1904, ii., 178-9, 182-5; *Bull. Imp. . *Coriaria*, Linn. The Sumach Tree of Europe, *tatra*, *mutchl*, *sumok*, etc. A small tree, wild in the Canaries, Madeira, the Mediterranean region, eastward to Afghanistan; often extensively cultivated. Inzenga (*Ann. di Agri. Sic.*, etc., Palermo, 1852) wrote an interesting paper on the cultivation of this plant (translated into English by Sir H. Yule, in *Edinb. Bot. Soc. Trans.*, 1867-8, ix., 341-55).

European
Sumach.

The leaves contain a colouring matter, and together with the twigs are largely used in Europe for TANNING. They are also imported into India, usually from Sicily, for use in the large European tanneries. Morocco leather is tanned with this material, and it is usually held to be one of the best for leathers intended for use in bookbinding. In the *Kew Bulletin* (1895, 293-6) an account of the manufacture of and trade in Sicilian sumach is given. The leaves ripen about

Tanning.

Morocco
Leather.

Season.	August, when the plant is cut down, spread on the field to dry, and the leaves stripped off and conveyed to the mills. Here the leaves are separated from all foreign admixtures and are then ground to powder. This powder is again subjected to a purifying process, after which it is ready for exportation and use as a tanning material. The real <i>sumach</i> is locally known as "strong," in contradistinction to a similar plant known as " <i>sommacco femminile</i> ," the leaves of which are smaller and of less strength than those of the former, in the adulteration of which they are largely used. [<i>Cf. Journ. Soc. Chem. Indust.</i> , 1902, xxi, 1207; Priestman, <i>Micro. Exam. of Sumach Adulterants</i> , in <i>Journ. Soc. Chem. Indust.</i> , 1905, xxiv., 231-3; Hanausek, <i>Micro. Tech. Prod.</i> (Winton and Barber, transl.), 1907, 300.]
Powder Prepared.	
Elm-leaved umach.	<i>Cotinus</i> , Linn. The Elm-leaved Sumach, <i>tunga</i> , <i>chaniát</i> , <i>ámi</i> , <i>páán</i> , <i>bauru</i> , <i>largá</i> , <i>manu</i> , <i>darengri</i> , <i>erandi</i> , etc. A shrub or small tree of the Suliman Range and Western Himalaya to Kumaon, ascending to 6,000 feet. Throughout the area of its indigenous habitat, leaves, bark and wood are all used in DYEING and TANNING, but whether they could be utilised on a commercial scale for this purpose is doubtful. Gamble states that the Wood is employed in South Europe for inlaid work and makes pretty carvings, picture-frames, etc. In the Himalaya, baskets are made of the twigs. [<i>Cf. Henry, Econ. Bot. China</i> , 1893, 42; Britton and Brown, <i>Illust. Fl. Northern United States and Canada</i> , 1897, ii, 389; Hooper, in <i>Agr. Ledg.</i> , 1902, No. 1, 21; Hanausek, <i>l.c.</i> 246-50.]

Wild Varnish.	<i>succedanea</i> , Linn. The Wild Varnish Tree, <i>arkol</i> , <i>lakhar</i> , <i>shash</i> , <i>tatri</i> , <i>raniwalai</i> , <i>serhnyok</i> , <i>dingkain</i> , <i>arkhar</i> , <i>choklu</i> , <i>hala</i> , etc. The galls are known as <i>kakar-singi</i> (<i>kakar</i> = the barking deer and <i>singhi</i> or <i>sing</i> = horns), but the true galls of that name appear to be those of <i>Pistacia khinjak</i> . A small deciduous tree of the Himalaya, from Jhelum to Assam, at 2,000 to 8,000 feet.
Exudation Collected.	Kaempfer calls this the Wild Varnish Tree, and says that in Japan the stem of this, as well as of <i>R. vernicifera</i> , is incised and the exudation collected for the manufacture of the varnish used in Japanese lacquer-work. In Japan the fruits are crushed, boiled, mixed with the fruit of another tree (said to be <i>Melia azedarach</i>), and pressed while hot. A wax is thus produced which is made into candles and sometimes sent to Europe under the name of "Japan Wax."
Wax.	The horn-like galls caused by insects on the branches and young shoots are sold as a substitute for those of <i>Pistacia</i> and are used medicinally. [<i>Cf. Lawrence, Valley of Kashmir</i> , 1895, 76; <i>The Bower Manuscript</i> (Hoernle, transl.), 1893-7, 25, 98; Dutt, <i>Mat. Med. Hind.</i> , 1900, 140.]
Galls.	
Japanese Varnish.	<i>vernicefera</i> , DC. This is the species which yields the famous Japanese Varnish. It grows all over the main island of Japan, and also in Kinshin and Shikoku, but it is from Tokio northwards that it chiefly flourishes. Efforts have been made to cultivate it in India, but without much success. The trees are propagated either by seed sown in January or February, or by cuttings from the roots of vigorous young plants. The juice, from which the varnish is obtained, is collected by making incisions on the stem, the punctures being repeated every fourth day at successively higher parts. The juice which oozes out is scraped off with a flat iron tool. When the tree has been tapped to its top-most branches, it is felled and cut into lengths, which are tied into faggots and steeped in water for ten to twenty days, after which the bark is pierced and lacquer collected in the same way as from the living stem. The juice thus collected is a tenacious fluid of a grey-brown colour. It is allowed to stand and settle, a skin forms over the surface, the better qualities rise to the top and the impurities sink. By stirring in the open air, the lacquer dries, absorbs oxygen and gains a brilliant black colour. The articles lacquered are invariably of wood. The varnish is spread in coats of increasing fineness, the surface being repeatedly ground down with hard charcoal and polished with the ashes of deer's horn, and relacquered again and again. The pattern, says Dr. Dresser (<i>Edinb. Review</i>), is sketched on fibrous elastic paper, which is warmed and fitted to the surface to be decorated, when the pressure of the hand is enough to transfer the pattern. If the pattern is to be in gold, the outline is then followed by a fine h pencil dipped in lacquer, which acts as size. When this has so far dried as to be sticky, gold-dust is shaken on it from a spoon. From Rein's detailed account, it would appear direct painting of the pattern is also practised for the higher class works. [<i>Cf. Rein, Indust. of Japan</i> , 1889, 338-78; Quin, <i>Lacq. 1899, 374; *Kew. Bull.*, 1904, 7-9; 1906, 138; Hosie, *Rept. on Prov. Ssu'ch'uan*, 1904, 29; *Illust. Acc. of Tree and Lacquer in Indo-China*, *Bull. Econ. L' Indo-China*, 1905, viii., 600; Tschirch, *Die Harze und die Harzbehälter*, 1906, ii., 851-85.]

RICINU CO MUNI, *Linn.*; *Fl. Br. Ind.*, v., 457; EUPHORBACEÆ. The Castor-oil Plant, Palma Christi, Ricin de Palma Christi, arand, erand, rand, bherenda, bindi, eri, areta, orer, rak-lop, anrar, gaba or jara, grundi, nerinda, rendi, harnauli, bazanjir, hérán, ind, rund, amanakkam, kottei, amadan, amdi, haralu, kesu, kyetsu, etc. These vernacular names are mostly derived from the Sanskrit *eranda* and *ruvuka*, with the alternative *vatari* (= anti-rheumatic). The Arabic *khirva*, the Persian *bedánjir*, the ancient Greek *kiki* and the *kroton* (Herodotus, ii., ch. 94) have had little, if any, influence on the origin of the existing Indian vernacular names. The name *Palma Christi* is used by Holland in his translation of Pliny (*Nat. Hist.*, 1601, 433).

A native of the tropics, where it exists as a perennial bush or small tree. Is in warm temperate tracts an annual and ascends the Indian hills to altitudes of 6,000 feet. Its cultivation seems also restricted by excessive moisture, the plant becoming again an annual (within the tropics), thus allowing of cultivation in the drier months. Rainfall after sowing, however, seems essential to liberal germination. It prefers well-drained loams, hence loose sandy or heavy clay soils are alike unsuitable. It is an exhausting crop, especially on the soil resources of nitrogen. Is exclusively propagated by seed, and in India, when grown as a pure field crop, is generally regarded as precarious, owing to its liability to being completely devoured by caterpillars. Mackenzie (*Eri Silk-worm*, *Cachar Exper.*, 1889, in *D.E.P.*, vi., pt. iii., 165) mentions a case where 30 acres were completely defoliated by caterpillars.

History.—Cultivated throughout India and naturalised here and there near habitations, distributed throughout the tropics generally, but probably indigenous to Africa. It is not, however, uncommon to discover it in the scrubby jungles of the outer Himalaya. Duthie speaks of it as naturalised in Merwara; it has been reported as wild and never cultivated in Upper Burma and universally self-sown in Assam—that is to say, in the gardens and waste lands, where its leaves are used to feed an undoubted indigenous silkworm. Taylor (*Topog. and Stat. Dacca*, 1840, 59) speaks of castor as found in the uncultivated parts of the district. In the *Susruta A'yurveda*, references to the plant are made in such terms as to preclude the possibility of the passage in question denoting an imported drug. Two varieties, a red and a white, are described, thus showing personal acquaintance with the plant. Its oldest Sanskrit name, *eranda*, has passed into the most diverse languages and dialects of India (Dutt, *Mat. Med. Hind.*, 1900, 231).

Dioscorides tells us that it was called *kroton* from the resemblance of the seed to the dog-tick, and it is significant that both the plant and the tick bear the name *Ricinus* in Latin (Pliny, *Hist. Nat.*, xi., 34; xv., 7). Galen, Paulus Ægineta, Mesua, etc., mention the purgative property of the oil. Avicenna, Rh es and other Arab writers add that it is a good application for cutaneous diseases and in rheumatism. But it would almost seem as if the Arabs had made acquaintance with the plant from India, since they call it *simsim-el-hindi* (*Sesamum* of India), and, as pointed out by the authors of the *Pharmacographia Indica* (iii., 302), the properties signed to the plant by the Arabs are those attributed to it by the Sanskrit authors. Pliny, moreover, speaks of the plant as not so very long ago introduced into Egypt.

Few of the early European travellers in India, however, make any reference to the plant. Garcia de Orta and Linschoten are silent. Aiton (*Hort. Kew.*, 1789, iii., 377) mentions that it was cultivated in England in the time of Turner, 1562. Rheede speaks of castor cultivated in Malabar, especially in sandy situations. Loureiro

refers to it as both cultivated and uncultivated in Cochin-China, while Rumphius says it grows in Java, being raised in large fields which thus afford much oil. It would appear that the medicinal oil of the West Indies was imported into India for fully half a century prior to any mention of the Indian-grown oil-seed or oil being recorded as exported. In 1761 Lewis spoke of the Palma Christi seeds being rarely found in the English drug-shops and the oil scarcely known. In 1764 Peter Canvane, a physician in the West Indies, published a *Dissertation on the Oleum Palmæ Christi, etc.*, giving *Oleum Ricini*, in which he strongly recommended its use as a gentle purgative. It was shortly after 1788 admitted into the London Pharmacopœia. Woodville (*Med. Bot.*, 1790 (ed. 1832), iii., 624-8) speaks of the oil as having lately come into frequent use. It was at the time obtained from Jamaica. In 1804 India imported 20,207 lb. of the oil, and as late as 1808 took 3,503 lb. Gradually, however, it seems to have been discovered that India itself produced the medicinal oil, and the exports in 1813 were valued at £610, and in 1819 at £7,102. Fifty years later, the exports of the oil had expanded from 2,000 to 100,000 gallons. No mention is made of the traffic in the seed, but it is thus evident that the European demand for this oil-seed and oil from India is quite modern. [*Cf. Joret, Les Pl. dans L'Antiq., etc.*, 1904, ii., 270.]

CULTIVATION.

VARIETIES AND CULTIVATED RACES.—Botanical writers allude to the multiplicity of forms that exist as proof of the antiquity of cultivation. Müller (in De Candolle, *Prod.*, xv., pt. ii., 1016-21) forms sixteen varieties or rather cultivated states that merge from the one to the other, but which are often agricultural forms of considerable value. Roughly, these have been grouped by most writers under two great types—(a) a tall bush or small tree of perennial growth, usually planted as a hedge or in lines through the fields where it affords desirable shade to other and more valuable crops. This gives a large seed with an abundance of inferior oil. (b) The other, an annual plant sometimes grown as a pure crop, though more frequently in mixed cultivation. It gives a small seed, the better qualities of which by an expensive and more careful process of expression afford the superior qualities of the oil of commerce, some of the finer grades of which constitute the medicinal oil of European pharmacy. The former, from its being extensively used in India for illuminating purposes, is often called "Lamp Oil," but it also finds a place as a valued lubricant.

Frequent mention is made, by writers on this subject, of a third important grade, namely a castor which by special selection has come to yield a seed that contains no poisonous principle, the oil of which is edible. Smith (*Contr. Mat. Med. China*, 1871, 55), for example, says that a "species or variety of *Ricinus* is said to have smooth fruit and to be innocuous." In Ahmadabad I collected (in a garden) a perfectly smooth-fruited form, the leaves of which were suffused with a white farina that gave them a remarkable glaucous appearance. I was told the oil of that plant could be used in cookery.

Bengal.—Mukerji (*Handbook Ind. Agri.*, 1901, 276-86) says that cultivation is chiefly in the Patna and Bhagalpur Division. There are three forms grown—a small, a medium, and a large-sized plant. The first and last are sown in May to July and grown with some *bhadoi* crop. The seed is ripe in January and February. The winter variety is sown in September and gathered in March-April. This yields a larger proportion of oil than the *bhadoi* crop. On *dearab* lands the cost of cultivation is little and the yield large. Red soils situated at the foot of the hills are specially chosen, but it is an exhausting crop, and should not be grown more frequently than once every five or six years. It is never irrigated, all the cultivation deemed necessary being a ploughing between the rows of plants to keep the weeds down. Picking usually takes place from the seventh to ninth month after sowing. When grown with other crops the yield of cleaned seed per acre is about 250 lb., and when grown by it lf, 500 to 900 lb. It is generally held that the large-seeded varieties yield the best ordinary lubricating and lighting oils, and that the small-seeded afford the finer grades, especially those used for medicinal purposes. [*Cf. Banerjei, Agri. Cuttack*, 1893, 88-9 Roy, *Crops of Beng.*, 1906, 84-6.]

Assam.—Basu, writing on the possibility of castor being grown in cor junction with indigo and tea, says that in the Assam valley it is never grown for its seed, but always for the leaf, which is used for feeding the *eri* silkworm (p. 1005). There are two varieties of the plant (a) the *eri* and (b) the *Bengali eri*. The former is indigenous and the latter introduced—a taller and stouter plant

Generally the crop is allowed to be self-sown, and is found in small patches in the gardens of those who rear the silkworm. The seed is allowed to shed and run waste, but occasionally careful people collect and sell it. The plant is found everywhere in Assam, though much less abundant in the Surma valley. It is also grown by certain of the hill tribes, such as the Garos, Mikirs, Kulkis, chiefly also for rearing the silkworm. Hindus do not engage in the production of *eri* silk, and its traffic is mainly in the hands of the Kacharis and Meches in the north of the Kamrup, Goalpara and Darrang districts, and accordingly the plant is most prevalent in the tracts of country occupied by them. But it is nowhere a regular field crop. No oil is extracted from it in Assam. In Tezpur and the Khasia and Jaintia hills, experiments were conducted, but the crops were destroyed by insects to which the plant is peculiarly prone, hence the opinion that when grown in large quantities it is a precarious crop (*Physical and Political Geog., Assam*, 37).

Districts chiefly Concerned.

United Provinces.—In the recent inquiry into castor as a possible supplementary crop with indigo, Mr. Moreland observed that he was unable to say if it would pay, since a *rabí* crop is usually taken after indigo, and this could not be the case were the land occupied with castor. So far as known, it is never sown mixed with indigo. Moreover, indigo does not require nitrogenous manures, so that the cake would have no special value to the indigo planter. Subsequently (in 1903) Mr. Madi (Assistant Director of Agriculture) wrote a note which affords full particulars regarding the methods of cultivation, harvesting, extraction of oil, cost of cultivation, and diseases. It would appear to be grown all over the provinces, on almost every kind of soil, though chiefly on rich loams. It is generally sown as a subordinate crop in the rainy season with *bájra*, *arhar*, *quár* or cotton, and, at the beginning of the cold season, with gram, wheat and barley. It is not uncommon as a hedge to sugar-cane fields, being in that case sown in March or April. It is seldom raised alone to any extent, except perhaps in Allahabad, where the *khadar* lands, on the banks of the Jumna, are often devoted to it. Castor is also largely used as a first crop on newly laid out gardens, perhaps to secure shade for young trees, for which purpose it is also occasionally grown by market gardeners.

U. Prov.

Production.

Soils.

Seasons.

Rotation.

In the *kharif* time a furrow is thrown up parallel to the sides of the field, and seed cast into this at a distance of every 3 feet. By the return course the seed is covered over. This system is carried throughout the field, the furrows being 6 to 10 feet apart, and when the sowing of castor is thus completed a higher ploughing is given over the entire field and the chief crop sown. Occasionally the castor is cultivated on the ridges that separate the water-beds, in irrigated land, and in that case, as also when sown as a hedge to fields, the seed is usually dibbled by hand.

Propagation.

The crop ordinarily takes eight to twelve months to mature. The small-seeded varieties ripen earlier than the large. The crop sown in March or April along with sugar-cane takes the full twelve months, while that sown after the rainy season is harvested in ten. The plants begin to produce ripe fruits in seven or eight months, and picking thus commences about January and continues till April. Mention is often made, in connection with Oudh, of the existence of a form with dark-brown seeds that is specially rich in oil.

Seasons.

Races.

The fruits are collected and stacked in the corner of a house, and covered over with straw or cloth. After six days the capsules soften and the shells decay. They are then exposed to the sun for two days and when well dried the shells split open, or if they do not open naturally they are beaten with a mallet until the shell separates from the seed. The fruits of the larger forms are buried in a pit excavated in the dung-heap, and the

Races.

mouth closed in with straw. After a week the fruits are removed from the pit, and the shells separated from the seeds. In some parts of the country the bunches of fruits are for some time then exposed to the sun.

A vigorous plant yields as much as 8 to 10 seers of seeds in a season, but those grown as hedges do not usually yield more than $\frac{3}{4}$ to 2 seers a year—the flowering being hindered by a deficiency of light and air. Usually the plants are cut down after yielding their crop, but when grown in gardens or near the homesteads they may afford a second or even a third crop in succeeding years, but in that case they are cut down each year to within two feet of the ground, the result being that they throw out numerous branches and give a large crop, though with an inferior quality of seed. In the third year the crop is poor both in quantity and quality. The average yield for an acre is 8 to 12 maunds the first year and 12 to 18 maunds the second when grown pure, or 4 to 6 maunds as a mixed crop. The produce sells at about Rs. 4 a maund.

The strongest and largest stems are used as timber (rafters) for thatching, and are also made into pokers for sugar-cane-boiling furnaces. The dried stems and husks are used as fuel or converted into charcoal and worked up in fireworks. The green leaves are eaten by cattle with apparent relish, and are believed to increase the flow of milk in cows and buffaloes. The cost per acre of pure cultivation is Rs. 24-2-0. If the acre produces 10 maunds, sold at the low average of Rs. 3 a maund, and allowing Rs. 5 as the price of the stems, fuel, etc., obtained, the balance over cost of production would show a net profit of Rs. 10-14-0.

Mr. Hadi mentions several caterpillars which eat the leaves and young shoots; an aphid which does much damage to the flowering shoots and young leaves; white ants which do much harm—in fact the castor-oil plant is more subject to their depredations than is any other regular crop; lastly, castor is much injured by frost. [Cf. Duthie and Fuller, *Field and Garden Crops*, 1883, pt. ii., 38-9, t. 43; Maxwell-Lefroy, *Mem. Dept. Agri. Ind.*, 1907, No. 2.]

Central Provinces and Berar.—There are two varieties ordinarily grown—(a) large-seeded, raised as a rainy season crop; (b) small-seeded, grown as a cold-season crop. Some few years ago (1899-1900) an estimate was made of the area under both crops, and it was then found the total came to something like 67,845 acres. It is included in official statistics under the heading of "Other Oil Seeds," which in the *kharif* season of 1905 occupied 262,477 acres, and in the *rabi* 85,188 acres. The districts of chief production are Betul, Raipur and Bilaspur. The large-seeded plant usually occupies waste or fallow patches in cultivated land. Any kind of soil suits it so long as it is well drained. The small-seeded variety is sown as a regular field crop in the month of September, about 16 to 20 lb. of seed being required to the acre. Sandy loams are preferred, and black cotton soil does not suit it. The seed is sown with a drill plough. One weeding is considered desirable when the plants are about 6 to 12 inches high. The crop is harvested in March as the pods are found ripe enough. The outturn is about 500 to 600 lb. per acre of cleaned seed. The seeds usually sell at 20 lb. per rupee. The oil is manufactured locally to but a small extent, to meet the demands as a lubricant for cart-wheels and preservative for leather. [Cf. Sly, *Note*, 1901.]

Panjáb.—The plant is nowhere systematically raised as a crop in the Panjáb, but exists (mostly self-sown) on embankments near canals, especially in Jhelum and Gurgaon. It is mentioned as abundant on the Jharsa and Raisina Bunds. The people pay no attention to it nor make any use of its seeds. Mr. I. H. Burkill contrasts the castor-oil plant of Baroda with that of the Northern Panjáb and Kangra, and adds that the latter is different from the ordinary form of the plant. The oil-mill at Lahore manufactures approximately 30,000 cwt. of this oil a year, the seeds being procured mainly from the United Provinces. An oil-mill has recently been opened in Delhi, and a demand for the seed thus exists that may

RABÍ AND KHARÍF CROPS

ICINU
CO U I
Cultivation

lead to extended cultivation. The oil is largely used for lubricating cold machinery and as an illuminant in railway carriages, hence most of the Railway Companies in India manufacture their own oil. It is supposed to give a clear light, to be highly economical since it burns slowly, gives little smoke, and does not generate heat sufficient to make it dangerous. Aitchison (*Afghan. Delim. Comm.*, 1885; also *Notes on Products, etc.*, 1890, 175) says the plant is cultivated along the banks of irrigation channels and margins of melon, cotton and tobacco fields, the seeds being collected to afford an illuminating oil. The seeds are crushed among cotton-wool, and the wool, saturated with oil, is subsequently, as required, made up in the form of tapers (*maluk*).

Uses of the Oil.

Afghan
Production.

Bo bay and Sind.—In 1899–1900, 44,094 acres were sown and 25,265 matured a crop—in Bombay proper, none having been recorded for Sind. In the following year, 65,646 acres were under the crop, but no mention was made of the proportion that was non-productive. In 1901–2 the cropped area was 109,475 acres, and in 1902–3 it stood at 119,049 acres. The following year it had declined to 94,257 acres; in 1904–5 there was a still further shrinkage, namely to 72,599 acres, but no mention of a Sind production, and in 1905–6 to 64,878 acres with 454 acres in Sind, practically all in Thar and Parkar. Mollison (*Textbook Ind. Agri.*, iii., 105–8) says both perennial and annual varieties of the plant are met with in India. The annual forms are *rabí* crops in Bombay Presidency, and the plants are very much smaller than the perennial, which are *kharij* crops. The latter grow with great rapidity, and a year's growth produces a tree 15 to 20 feet high. The foliage, branches and stems, according to variety, may be bright pale green, or green tinged with red, bright shining red, or bronze purple. Forms with the last-mentioned description of foliage are often grown as decorative plants in gardens. Mollison also states that the seeds vary in size and markings. "One Bombay variety has large seed, black in colour, with tiny specks of white. The perennial varieties are chiefly grown along irrigation water channels, on the borders of sugar-cane and in highly cultivated market garden land, and a plant soon gains the dimensions of a tree." The seed is sown, as a rule, about July. The shade which the perennial castor affords to ginger, turmeric, sugar-cane and other such crops is often valued. Perennial castors are easily cultivated and readily escape from cultivation, and consequently are often found wild in many localities.

Bombay.
Areas.

Races.

Variegated
Forms.

Seasons.

"The plant does best in deep free working soil. The very best crops in the Presidency are produced on the *bhatha* (alluvial) soils which fringe the course of the Tapti in Surat." "In the sandy *goradu* soils of Northern Gujarat, a sprinkling of castors is usually found in the subordinate mixture (*kathol*) of cereal crops sown in *kharij* season." "The *rabí* crop (a comparatively dwarf plant) requires soil of different character. A retentive clay soil or the soil of moisture-holding rice beds is suitable. On black soil the *rabí* crop is generally sown mixed with *tuver*, *til* or with gram, and this mixed crop is generally the sole crop of the year. In this case the land is well fallowed during the rains, and the mixed seed is sown in September. In rice-beds, castors and *val* or castors and gram are second crops sown in October or as soon as possible after the rice is removed."

Soils.

Mixed Crops.

Castor has been grown alone on the Nadial Farm, and the best outturn obtained, Mollison observes, was 1,390 lb. of beans per acre; and this was in a specially favourable year. The *kharij* (perennial) crop is very hardy, especially in fairly deep soils. It, however, does best on rich garden land freely manured and watered. Mixed castor and ground-nut is a characteristic *kharij* crop. An experimental crop of this nature at the Surat

Yield.

Farm yielded 767 lb. castor bean per acre, worth Rs. 43-14a., and a good ground-nut crop with castor might yield in addition 2,500 lb. nuts per acre.

Madras.—The Madras Board of Revenue unofficially furnishes the area under castor for the five years ending 1900. It may be useful to review the figures in question. The area under the crop might be regarded as shrinking. In 1895-6 it occupied 751,173 acres, and in 1896-7 it was produced from 782,135 acres, but from that date it would almost seem to have declined, until in 1899-1900 it was returned at 600,214 acres. The districts of greatest production are Anantapur, 128,476 acres in 1895-6 and 74,422 acres in 1899-1900; Bellary, 111,599 and 90,227; Cuddapah, 110,091 and 87,023; Karnul, 94,517 and 65,924; Kistna, 91,325 and 80,804; Nellore, 50,880 and 42,729; and Coimbatore, 39,470 and 34,567; the figures shown indicating the acreage in the years in question. The returns for the year 1905-6 show the area to have been 380,100 acres, or 32 per cent. less than the average of the ten years previous, which came to 563,100 acres; and the chief production was in the Deccan.

Francis (*Gaz. Bellary*, 1904, 111) describes a method of grinding the seeds which prevails in that district. A machine is used like that commonly employed for making mortar, and consists of heavy stone wheels dragged round by bullocks in a circular stone-lined channel in which the seeds are placed. The paste so resulting, he adds, is boiled with water and oil rises to the top and is skimmed off. The stench caused is, however, most offensive, and the cake obtained is used as the fuel for roasting the next batch of seeds. [*Cf. Shortt, Man. of Ind. Agri.*, 241-5; *Castor-Bean Crop*, issued by Board of Rev., 1899-1905.]

Burma.—The Director of Land Records observes: "There is no trade in castor-oil by land or by sea, except that imported as medicine or in a semi-crude state for lubricating purposes. The plant grows wild over a large area in Upper Burma." "The plant is not cultivated in any part of the province."

EXPRESSION OF OIL.

It has still to be confessed that the report written by Col. Hawkes, in 1853, is the only authoritative statement that has appeared. Hooper (*Rept. Labor. Ind. Mus.* (Indust. Sec.), 1903-4, 26-7) gives certain practical results. Two samples of Nairobi (British E. African) seed were examined—the larger form yielded 47·35 per cent., the smaller 43·35 per cent. of fixed oil by ether extraction. Dubard and Eberhardt obtained an average of 46·19 per cent. with East Indian castor seed, and by the ordinary crushing and heating with water about 37·40 per cent. of oil is extracted. Leather (*Mem. Dept. Agri. Ind.*, 1907, i. (*Chem. ser.*), 32-5) gives the results of numerous examinations.

Bengal.—N. G. Mukerji remarks that there would appear to be four methods of extracting the oil practised by the people of Bengal. (1) The seeds are crushed in a screw-press with horizontal rollers and the resulting pulp pressed in gunnies. The cold-drawn oil thus obtained amounts to 36 per cent. (2) The seeds are roasted, pounded in a mortar and placed in four times their volume of water kept boiling. The mixture is constantly stirred, and the oil skimmed off as it rises to the surface. (3) The seed is first boiled, dried for two or three days, then pounded in a mortar and boiled in four times its volume of water kept boiling, and the oil skimmed as in (2). Lastly (4), the seed is soaked overnight in water, ground in the morning in a gunny, and then squeezed within cloth till the oil has been obtained. It is generally stated that cold-drawing with proper machinery is the best and most profitable method. The kernels are pressed in gunny bags and the oil is thereafter bleached by exposure to the sun, which causes a sediment to precipitate. The oil is then filtered through vegetable charcoal and flannel bags. In some cases a fire is placed underneath the machine in which the

CALCUTTA AND MADRAS MILLS

C I U
C U I
Oil

bags are being pressed. This is said to increase the yield by 10 per cent., but it is believed some of the noxious properties of the seed are then liable to pass into the oil.

The castor-oil mills of Calcutta use up on an average close on 700,000 cwt. of seed, drawn mainly by the railways from the province of Bengal and from the United Provinces. The quantities obtained from the other provinces are inconsiderable. The large-seeded form, which they mainly use, comes from the provinces named, while the small-seeded is derived from Madras, being mainly imported by coastwise steamers. There were in Bengal 75 oil-mills that gave, in 1904, employment to 2,836 persons. These doubtless are mainly Calcutta mills, concerned chiefly, if not entirely, in the production of castor, and furnish the quantities of that oil exported from Calcutta to foreign countries. As compared with these figures, Madras had 24 oil-mills that employed 1,476 persons during 1904, but these are not by any means so largely castor-oil mills as is the case in Calcutta. The total of the oil-mills in all India came, in 1904, to 112, so that the Calcutta and Madras series represent by far the major interests in the traffic. During that year Bombay possessed only two oil-mills with 226 employees.

United Provinces.—Two different methods of extracting the oil prevail in these provinces. In one the seed is pounded and boiled, and in the other pressed in a mill. The former is the method which might be described as pursued by small growers and for domestic purposes.

The seeds are cleaned by various processes, roasted, pounded, and then boiled in water. The oil rises to the surface and by different contrivances is skimmed off or decanted, and the boiling continued, the mixture being repeatedly stirred until exhausted of its oil, the last dregs rising to the surface as the fluid cools. The water mixed with the oil is next removed by reboiling until it evaporates; the impurities at the same time sink to the bottom, while the pure oil floats on the top and is decanted. The *bhurjis* (or professional grain-parchers) are the persons who by caste are alone permitted to roast castor-oil seeds and prepare the oil by the above method when required for commercial purposes. All others would be outcasted were they to engage in the traffic, except for purely domestic necessities.

The extraction by pressing-mills may now be briefly described. About 15 seers are cleaned and husked by beating with a stone, the result being about 12 seers of kernel. That quantity is then placed in the ordinary wooden oil-mill. About one seer of boiling water is then added and the outlet of the mill plugged up until about half a seer of oil has been formed—or, say, after the kernels have been ground for 10 to 12 minutes. Meanwhile, also, the contents of the mort are constantly heated by means of a burning torch, since heat facilitates the flow of oil. The oil that collects from the mill is removed, heated, and again poured back through the mill to help the further separation, and this is repeated until the cake produced has been exhausted. The whole of the oil is then boiled to drive off the water and cause the precipitation of the impurities. The oil produced under this method is regarded as superior to that obtained by the boiling process. The average yield is about 33 per cent.

European Machinery and Methods.—Here and there all over the country, more especially at the jails, castor-oil is manufactured by modern European machinery. Certain centres are even famous for this oil, such as Calcutta and Madras (in the latter Presidency more especially at Godavari, Kistna, Nellore and Coimbatore). But European and American improved and expensive machinery has raised the standard of the oil as well as lowered the cost of production, the result being that the competition has told seriously on the antiquated methods followed in India as a whole (*Capital*, Jan. 24, 1894). It has, for example, been found unnecessary to husk the seed, since the husk neither absorbs oil nor imparts colour; and by using the whole seed, 41·93 per cent. of oil may be obtained by some of the newer and more satisfactory systems. These include a hydraulic press but dispense with crushing-rollers, kettle, moulding machine and cloths—economies that have effected a great saving on the older methods.

Industrial Uses.—The oil is largely burned, some few years ago more extensively than at the present time. It is believed to give a cooler and brighter light than other vegetable and mineral oils, and to burn more steadily. Twenty-five to thirty years ago, at most, every European resident in India, and all the wealthier Natives as well, employed either castor-oil or cocoa-nut oil exclusively for house illumination (see

ils, p. 812). The value of castor-oil as a preservative has long been known, and on that property depends its employment on leather goods of all kinds, also as a lubricant for machinery. It is frequently employed by the Indian dyers as an auxiliary in certain tinctorial results, and similarly by calico-printers. The ordinary Native oil is sold in the United Provinces at Rs. 10 to 16 per maund, the price of course varying with the quality, but the medicinal oil and the purer grades may fetch as much as Rs. 24 to 27 a maund. Medicinally the oil holds an important position, and the white seed is specially preferred for that purpose.

Turkey-red Oil.—This is a specially prepared oil used in mordanting alizarin-dyed fabrics and for dressing tanned leather. The extent to which the Indian manufacturers are using that dye may be judged of by the demand. A difficulty was long felt in turkey-red dyeing to obtain an oil that would diffuse readily in water. By the old process the fabrics and yarns to be dyed had to be soaked in oils for a week or more. By the use of a sulphoricinate of soda the objects of the oil mordant may be attained expeditiously, and turkey-red dyeing has thereby been greatly simplified. Almost any oil may be employed, but Indian castor has been found the most suitable, and may be said to enjoy a monopoly in meeting this new and increasing requirement. It may be suggested that a profitable opening exists for the manufacture and exportation of turkey-red oil in place of having to import the supplies required by the Indian dyers. [*Cf. Blount and Bloxam, Chem. for Engin. and Manuf., etc., 1900, 235-6.*]

Castor Oil-cake.—The oil-cake is regarded as a good fuel, but it is never given as food to cattle. Is fairly largely used by cobblers for stuffing the soles of the shoes they make or repair. The cake is generally stated to contain the whole of the poisonous property of the seed, hence its not being used as an article of cattle food. It is, however, rich in nitrogen and therefore much in demand as a manure, especially for potato and sugar-cane. In some parts of India the cake, and even cheap castor-seed, are used in the manufacture of gas, which is treated exactly like coal-gas, and is in some respects superior to it. Where coal is scarce and expensive, this utilisation of castor is deserving of more consideration than has as yet been bestowed on it.

TRADE IN CASTOR SEED AND OIL.

Foreign.—It is significant that Milburn, in 1813 to 1825, should say nothing of the EXPORTS of castor-seed from India, though he makes mention of a small traffic in the oil. Hawkes states that the average export of castor-oil during 1850-5 came approximately to 100,000 gallons. By 1878-9 the exports of the oil were 2,119,755 gallons, valued at Rs. 31,53,969, and of the seed 74,214 cwt., valued at Rs. 5,00,056. Ten years later these items were (1888-9): oil, 2,092,913 gallons, valued at Rs. 20,31,467, and seed, 585,769 cwt., valued at Rs. 31,28,741. The exports for the five years 1902-7 were as follows:—1902-3, oil, 2,073,573 gallons, valued at Rs. 24,68,222; 1903-4, 1,916,200 gallons, valued at Rs. 20,83,239; 1904-5, 1,632,106 gallons, valued at Rs. 16,43,982; 1905-6, 1,432,108 gallons, valued at Rs. 17,12,088; and 1906-7, 1,445,636 gallons, valued at Rs. 22,22,015. Similarly seed:—1902-3, 1,751,688 cwt., valued at Rs. 92,05,666; 1903-4, 1,566,838 cwt., valued at Rs. 69,19,562; 1904-5, 1,460,908 cwt., valued at Rs. 69,15,892; 1905-6, 1,298,624 cwt., valued at Rs. 78,66,786; and 1906-7, 1,505,059 cwt., valued at Rs. 1,14,16,925.

It would thus appear that since 1888-9 the quantity of castor-oil exported has declined by fully half a million gallons, but the price has considerably improved. The traffic in castor-seed, on the other hand, has very materially increased within the period indicated, namely from half a million to one and a half million cwt. These circumstances thus

seem to show that the Indian castor-oil mills are not advancing with the world's demand, an indication apparently of defective methods, or of want of capital and enterprise in keeping up with the improvements in production effected in Europe. This subject seems well worthy of serious consideration. India enjoys a distinct position of advantage in the production of the seed, and an export of so bulky and weighty a product could only be profitable through greater returns in the oil-production. The exports in oil go almost entirely from Bengal, Madras coming next with about a tithe of the Calcutta traffic. The countries to which exported may be best illustrated by the figures of 1905-6 in gallons:—To Australia, 293,677; to Natal, 255,528; to the Straits Settlements, 201,169; to the United Kingdom, 191,034; to New Zealand, 111,748; to Mauritius, 105,867; to Cape Colony, 92,070; to China (Hongkong), 68,392; to all other countries, the balance on the total of 1,432,108 gallons.

Oil Traffic.

From
Calcutta.

Countries to
which
Exported.

The expansion in the traffic of castor-seed has been remarkable. The record year was 1902-3, and since then the quantity has somewhat diminished, but in 1906-7 the price realised considerably improved. France formerly was the chief consuming country, but within the period named the demands of the United Kingdom have greatly increased, as also those of Belgium, Italy and Germany, while France has fallen off materially until it occupied in 1904-5 the third place, and in 1905-6 the second place among the receiving countries. Bombay is the chief exporting province: out of the total of approximately 1½ million cwt. the western capital supplied fully one million, the balance having gone from Madras and Sind. The producing regions for this export traffic would appear to be the Nizam's Territory and Bombay Presidency, which between them supplied 99 per cent. of the total amount exported from Bombay town. The balance is derived from the Central Provinces and Berar. Hyderabad is the chief centre. The Karachi exports are doubtless Panjáb and Rajputana castor-seed, since, as already shown, practically no castor is grown in Sind. Bengal exports no castor-seed.

P A C R AG.—Many fibres are used for this purpose by the agricultural communities and hill tribes of India. Rural people are never, in fact, at a loss to find a bark or twig that may be extemporised into a fairly strong green string, quite suitable for tying bundles or even

Ropes and

Fibrous
Materials.

repairing cattle-yokes. And many such plants are often utilised in the systematic preparation of the ropes offered for sale at the village shops or market-stalls. More rarely they are specially cultivated, in small plots or strips through the fields, as hedges on the borders of fields or by the water-courses and creeks. It might in perfect fairness be said that many of the discoveries regarding the fibrous resources of India were the outcome of the demand for serviceable ropes to be substituted in the British and Indian navies for Russian hemp. Roxburgh, the great pioneer in economic botany, wrote a special report of his experiments and discoveries (see *Cannabis*, pp. 253-4; also *Linu*, p. 722). This was followed by many other publications (Royle, *Fibrous Plants*, 1855, 19-26; Baden-Powell, *Pb. Prod.*, 1868, 476-7; Gee, *Monog. Fibrous Manuf.*, 11-3). These and such-like works give numerous details of the indigenous fibres and the local methods pursued in their utilisation. The reader should, therefore, consult the articles under the following rope and cordage plants:—

The Indian rope manufacturers who prepare cordage and rope by European machinery employ a comparatively small number of these fibres. They obtain local supplies of coir, jute, *san*-hemp, cotton, and Deccan-hemp, but as a rule import agave and sisal, hemp (Russian), and Manila. India has recently begun to grow *Agave* on a large scale, and the local production, if it has not already checked the imports of that fibre, may shortly be expected to do so. The production of Manila hemp cannot be said to have been quite so successful. Recently attention has been drawn to the possibility of using linseed stems (flax), in the production of cheap fibre to be used up in the growing demand for cordage as "binders." One of the jute-mills of Calcutta made the attempt some few years ago to contest the large Indian market for cheap and neat European-made string, by producing various qualities of cordage, done up in balls after the familiar fashion and in various colours. Jute rope is also, to some extent, made at the roperies, and cotton ropes have for long been used by the tent-makers as being more serviceable for that purpose than any other class of ropes. The other rope fibres of the above enumeration are almost exclusively employed by the people of India locally, and of these perhaps few are more important or more extensively employed, especially in North India, than *munj*, and in South India than coir. For fishing-lines and extra strong and

fine cordage, the fibres in most general use are *Bahmeria*, *Calotropis* and *Crotalaria*.

Trade in Ropes and Cordage.—The factories and rope-works that give employment to less than 25 persons are not recorded in official statistics. In 1901 there were 11 rope-works that gave employment in all to 2,538 persons; the year following, the figures were 12 rope-works and 2,814 employees; in 1903, 14 rope-works with 2,535 employees; and in 1904, 19 works with 2,954 employees. Of these rope-works 12 were in Bengal and 6 in Madras, one being recorded in Burma. Trade.

Imports.—The rope and cordage brought to India in 1876-7 were valued at Rs. 2,60,781; in 1886-7 at Rs. 3,22,940; in 1896-7 at Rs. 4,34,724; and during the five years 1902-7 were, in 1902-3, Rs. 6,29,703; in 1903-4, Rs. 5,90,380; in 1904-5, Rs. 6,32,651; in 1905-6, Rs. 6,75,798; and in 1906-7, Rs. 6,87,048. These do not, however, include jute rope and twine, the imports of which seem to be increasing. In 1900-1 they were valued at Rs. 17,722; in 1903-4 at Rs. 30,620; in 1904-5 at Rs. 26,434; in 1905-6 at Rs. 41,271; and 1906-7, Rs. 37,927. The bulk of these imports come from the United Kingdom, the next most important country of supply being China (Hongkong), and following that, the United States of America. The receiving provinces are Bombay and Burma, which usually take (in equal proportions) five-sixths of the supply, the next most important province being Bengal. Imports.

Exports.—India also exports rope and cordage, the supplies in 1876-7 having been valued at Rs. 2,65,603; in 1886-7 at Rs. 2,93,191; 1896-7 at Rs. 5,30,959; and during the five years 1902-7 the exports were—1902-3, Rs. 6,96,087; 1903-4, Rs. 6,18,109; 1904-5, Rs. 5,67,013; 1905-6, Rs. 6,48,909; and 1906-7, Rs. 7,03,779. Of these exports by far the largest quantity goes to the Straits Settlements, followed by the United Kingdom, Cape Colony, Arabia, Persia, Siam and Turkey-in-Asia. Of the exporting provinces, Bengal comes first, having supplied in 1906-7 one-half of the total exports, the next province of importance being Madras. Exports.

O A, Linn. ; Fl. Br. Ind., ii., 363-8 ; Gamble, Man. Ind. Timbs., 1902, 318-9 ; ROSACEÆ. A genus of erect or climbing shrubs, comprising about thirty distinct species with numerous cultivated sub-species and varieties. All are known by the vernacular generic name *gulab*, and indeed such other vernacular names as do exist are used indiscriminately for the various species. In spite of this fact, India has many both wild and cultivated roses. Rashid-ud-Din, in the 14th century, spoke of Gujarat, where the inhabitants were rich and happy and possessed no less than seventy different kinds of roses. Baber (*Memoirs*, 1519, 341) tells us that he never lost an opportunity of planting roses (1526). The Emperor Jahangir (*Memoirs* (Price, transl.), 1605, 14) speaks of Hindustan as possessing every sort of rose, particularly the musk and damask. It is, therefore, a curious circumstance that Fryer (*New Acc. E. Ind. and Pers.*, 1675, 104) should have spoken of Surat as a place where roses would grow if they would but cultivate them. The most important Indian roses economically are the following, in alphabetical sequence :—

D. .P.,
vi., pt. i.,
559-69.
Rose.

. centifolia, Linn. The Hundred-leaved or Cabbage Rose, *gulab*, *golap*, *Cabbage troja*, *paninir*, *mawar*, etc. A native of the Caucasus and Assyria, but cultivated in India from ancient times. This is said to be the chief rose cultivated in Persia for the manufacture of *attar* and rose-water, but in India the next species is the one most used for that purpose. Cabbage Rose.

Damask
Rose.

. *da ascena*, Mill. The Damask, Bussora, or Persian Rose, *guldh*, *sudburg*, *irojāppū*, etc. Perhaps the commonest Indian garden rose. In India, *attar* of roses is said to have been first discovered by Nur-i-Jehan Begum, in 1612, on the occasion of her marriage with the Emperor Jahangir. In English commerce

Attar.

attar of roses began to be recognised only in the beginning of last century. The *attar* imported by Great Britain is, however, almost entirely produced in Europe, chiefly Bulgaria and Germany. The Indian product is consumed in the country, and is apparently not exported. The chief seat of the industry is at Ghazipur on the Ganges, where distilleries have existed for fully two centuries. The following information is abstracted from the account by Jackson (*Journ. As. Soc. Beng.*, 1839, viii., pt. i., 411-4). The gardens where the roses are cultivated are let out annually by their owners at about Rs. 5 per *bigha* for the land, and Rs. 25 per *bigha* for the bushes, about 1,000 of which go to a *bigha*. The expense of cultivation amounts to about Rs. 8-8 per *bigha*, and 1,000 bushes should yield one lakh of roses, which are sold to the distillers at from Rs. 40 to Rs. 70 per lakh. The roses flower in March and continue throughout April. In the early morning they are plucked and carried to the distillers. The distilling apparatus consists of a copper or iron boiler with a large body and narrow neck, united by a bamboo tube with a long-necked vessel or receiver, called a *bhubka*. The boiler is let into an earthen furnace, while the receiver is kept in a *handi* of water, which is changed as it gets hot. The boiler is charged with the roses, over which a sufficient quantity of water is poured and distillation is then proceeded with. The rosewater should always be twice distilled, the water from the first distillation being used to pour over the roses for the second. The distilled rosewater is then taken from the receiver, placed in a glass *carboy* and exposed to the sun for several days to become ripe. The mouth of the carboy is then covered with cotton, over which is put a coating of moist clay, to prevent the scent from escaping.

Ghazipur.

Rent.

Season.

Distilling of
Rose-water.

Ripening.

Separation of
Attar.

To procure *attar*, the distilled rosewater is placed in a large metal basin which is protected by wetted muslin to exclude insects and dust. This vessel is then let into the ground, which has been previously moistened with water, and allowed to remain for the night. The cooling causes a little film of *attar* to form on the surface of the rosewater, and this is removed in the morning and placed in a small phial. The first few days' distillation does not procure such fine *attar* is obtained afterwards (see p. 821).

Adulteration.

Sandal-wood.

Perfumery.

Much of the rosewater of India is adulterated with water before being sold, and indeed the *attar* can never be obtained pure, since it always contains sandalwood oil. Sandalwood chips are very generally added to the flowers before they are distilled. This was mentioned by Engelbert Kaempfer in connection with Persia so long ago as 1682. Gildemeister and Hoffmann (*Volatile Oils*, 425, 423-36) state that as far back as 1787 Polier observed in Kashmir that the Indian grass (? *Cymbopogon Schoenanthus*, p. 461) was added to the roses for distillation. This grass does not, however, appear to be used in India for that purpose. The principal utilisation of *attar* is in perfumery and the manufacture of snuff and soap (rose-soap) (Alex. Watt, *Art Soap-making*, 1901, 149). In India it is largely employed by Natives at weddings and festivals. The best bazar *attar* is said to be sold for Rs. 10 per *tola* down to Rs. 2 for the inferior sorts. In the trade statistics, one or both of the above substances must be returned under either Essential Oils or Perfumery, details of the trade in which will be found under these headings. [Cf. Mesua (ed. Marinus), 1562, 54-5 and plates (one of the earliest authors to describe and illustrate the distillation); Milburn, *Or. Comm.*, 1813, i., 141; ii., 237; Bentham, *Rev. of Targioni-Tozzetti, Journ. Hort. Soc.*, 1855, ix., 179; Elliot, *Ind. Indust.*, 1880, 368; Sterling, *Cult. of Roses, Bot. Gard. Calc.*, in *Journ. Indian
Madder.

RU IA, Linn.; *Fl. Br. Ind.*, iii., 202-4; Prain, *Beng. Plants*, 1903, i., 580; RUBIACEÆ. A genus of erect, diffuse or climbing herbs, of which the most important economically are the Indian and European Madders.

. *cordifolia*, Linn. The Indian Madder, *manjīt*, *manjistā*, *majethi*, *manjitti*, *dandū*, *kukarpahā*, *madar*, *shevelli*, *tāmra-valli*, *man-chetti*, etc. A herbaceous creeper, throughout the hilly districts of India, from the North-West Himalaya

eastward and southward to Ceylon. It is a very variable plant, but there are two easily recognised primary forms:—(1) *cordifolia*, proper, with leaves five, rarely three-costate, veins impressed and surface rough or hispid; (2) *khassiana*, leaves three, rarely five-costate, veins not impressed and surface smooth. The latter is the richer in madder dye-principle. Two Forms.

Manjit root obtained from this plant was formerly much employed by the Natives of India in dyeing coarse cotton fabrics into various shades of scarlet, coffee-brown or mauve. It has been largely displaced by the tar dyes, but is still employed for special purposes or in remote localities. The method of dyeing practised is much the same all over India, the colour being produced by steeping the cloth in an infusion of the stem or root-chips, subsequent to being mordanted with a solution of alum. In former times madder was considerably employed in Native medicine, but to-day its uses are restricted to a colouring agent for certain oils. The trade in madder has for years been gradually declining, due to the substitution of artificially prepared alizarin and other aniline dyes. The imports of madder and *manjit* into India amounted in 1885-6 to a value of Rs. 2,02,038; in 1889-90 to Rs. 29,488; in 1900-1 to Rs. 16,562; in 1904-5 to Rs. 3,784; in 1905-6 to Rs. 11,365; and in 1906-7 to Rs. 5,405. The principal supplying country is Persia, and Bombay the importing province. Extraction of Dye.

The exports have almost disappeared, though small quantities still are re-exported, viz., in 1904-5, 249 cwt., valued at Rs. 3,277; in 1905-6, 211 cwt., valued at Rs. 2,538; and in 1906-7, 99 cwt., valued at Rs. 1,500. [*Cf. The Bower Manuscript* (Hoernle, transl.), 1893-7, 104, 107; Milburn, *Or. Comm.*, 1813, ii., 218; *Pharmacog. Ind.*, ii., 231-2; Banerjei, *Agri. Outcalt*, 1893, 200; *Ann. Rept. Ind. Mus.* (Indust. Sec.), 1894-5, 26, 34; Lawrence, *Valley of Kashmir*, 1895, 68, 92; *Monographs, Dyes and Dyeing*:—Duncan, *Assam*, 1896, 44, 45; Hadi, *U. Prov.*, 1896, 78; Banerjei, *Bengal*, 1896, 25; Russell, *Cent. Prov.*, 1896, 7, 17-8; *Rept. and Prog. Coll. Ind. Mus., Calc. and Imp. Inst.*, 1895-6, 71-3; *Imp. Inst. Tech. Repts.*, 1903, 211; Hosie, *Rept. on Ssu'ch'uan, China*, 1904, No. 5, 42-3, 48.] Imports.

R. sikki ensis, Kurz. The *moyum*. A handsome creeper of the Eastern Himalaya in Sikkim and Bhutan, at 2,000 to 5,000 feet, Mishmi Mountains of Upper Assam, Manipur and the Naga hills. Exports.

This species is the source of the brilliant red dye used by the tribes in the Naga hills and Manipur to dye both cotton and hair, the latter mostly human, employed to ornament their spears, etc. It is probable that the bulk of the madder plant of Assam is derived from this species, and that a considerable portion at least of the dye exported from Sikkim may also have the same origin. [*Cf. Watt, Cat. Calc. Inter. Exhib.*, 1883, ii., 55; Perkin and Hummel, *Colour. Principle of R. sikkimensis*, in *Trans. Chem. Soc.*, 1893; Duncan, *l.c.* 46-7.] Naga Madder.

. tinctoru, Linn. European Madder, *bacho*, *manyunth*, *rodang*, etc. A climbing herb with perennial roots, cultivated in Kashmir, Sind and throughout Afghanistan; distributed westwards from Persia to Spain, cultivated or wild. De Candolle considers its original habitat to be west temperate Asia and South-East Europe. Hair Dye.

The dried and ground roots formerly constituted one of the most valued of dye-stuffs, both in Europe and Asia, but the natural dye has been almost entirely replaced by artificial coal-tar derivatives. In the *Memoirs* of the Emperor Baber (Leyden and Erskine, transl., 148) we read that madder was largely cultivated in Ghazni and was carried thence all over Hindustan. To-day the plant is cultivated to a small extent, the best-known qualities of the dye (in European commerce) being Avignon, then Dutch, Alsatian, Levant (or Turkish madder) and Italian. It is propagated either from seed or by root-cuttings. The roots are allowed to remain for three or even five years before being removed for use. In India, cultivation is carried on chiefly in Kashmir and in some parts of Sind. The Indian methods of dyeing employed with this species do not differ from those used with the indigenous *R. cordifolia*. Both in India and Europe the plant is employed as fodder for cattle, and in Sind camels are said to be specially fond of it. [*Cf. Bentham, Rev. of Targioni-Tozzetti*, in *Journ. Hort. Soc.*, 1855, ix., 150-1; De Candolle, *Orig. Cult. Plants*, 1882, 41-2; Thorpe, *Dict. Appl. Chem.*, 1899, ii., 480-6; Rawson, Gardner and Laycock, *Dict. of Dyes, Mordants, etc.*, 1901, 223-7; Wiesner, *Die Rohst. des Pflanzenr.*, 1903, ii., 538-48; Goodwin (Queen's Univers., Toronto), *Madder and Indigo*, reprint in *Ind. Planting and Gard.*, Feb. 28, 1903, 203-4; Joret, *Les Pl. dans L'Antiq.*, etc., 1904, ii., 348.] European Madder.

ugars.

ACCHARU, *Linn.*; *Fl. Br. Ind.*, vii., 118-21. A genus of perennial grasses containing twelve species, chiefly Asiatic. Five are indigenous to India, in addition to sugar-cane, which is extensively cultivated.

SUGAR AND SUGAR-CANE.—Though chiefly obtained from sugar-cane, sugar may be procured from many other plants, of which the following, arranged alphabetically, are those best known :—

Maple.

Acer saccharu, the Sugar-maple of the Northern States of America and of Canada.

Javan
Palm.

Arenga saccharifera, the Sago-palm of the Malaya, also met[with] in Burma and Orissa. In Java, palm-sugar is prepared from the sap in much the same manner as from the date-palm in India. Marco Polo (*Travels, etc.*, 1290 (ed. Yule), ii., 235-6) alludes to the wine of Sumatra made from this tree (see pp. 91-2).

D.E.P.,
i., 448-50.
Beet.

Beta vulgaris, *Linn.*; *Fl. Br. Ind.*, v., 5. Beetroot and Mangold-wurzel, *palang*, *palak* or *bitpalang*; **CHENOPODIACEÆ**. Is fairly largely cultivated in Indian market gardens as a vegetable, and the seeds are used as a cooling medicine. Much attention has also been paid to the possibilities of mangold as an article of cattle food. It is mentioned by Buchanan-Hamilton (*Stat. Acc. Dinaj.*, 194) and described by Roxburgh, but there can be no doubt it is of quite modern introduction and has neither a classic nor any good vernacular names. Most of the Asiatic names given to it are special adaptations from the names of older and better known vegetables.

Indian
Interest.

But for many years the subject of beet-sugar has in India become one of great moment. So long ago as 1863 Royle, in his address to the Royal Asiatic Society, commended the subject to the attention of Indian investigators and administrators as worthy of serious consideration. Numerous experiments have been conducted in India with the object of establishing beet cultivation as a field crop, but so far with indifferent results. In the *Report* of the Department of Land Records and Agriculture, Panjáb, 1899, it is stated that the Cawnpore Sugar Works Company had been able to produce beet up to the average on the Continent of Europe. Experiments were accordingly started in Hazara, but without much success. Mention is made of experiments at the Botanic Gardens of the Nilgiri hills. In subsequent experiments at Saharanpur the crop was considered fair, and at Cawnpore in 1899-1900 the opinion was formed that to obtain the best result beet should be sown about the middle of October. Leather gave the opinion that both in outturn of root and yield of sugar, beet can be successfully grown in North India as a *rabi* crop, provided suitable land and facilities for liberal irrigation be devoted to it. The *Report* of the Botanic Gardens of Saharanpur for 1900 gives a detailed account of further experiments. Proudlock, writing of the Nilgiri hills, says that with ordinary care sugar-beet can be successfully grown. But the yield of sugar from all the Indian experiments rarely exceeded 13·10 per cent., while in some instances only 5·6 or even 3·3 per cent. were recorded. As a rule the roots grew too large, and in consequence the percentage of sugar decreased. A serious objection to beet cultivation is the necessity for deep ploughing, which the Indian cultivator is both unable and unwilling to perform.

Season.
Outturn.

Yield.

Failures.

P. V. Subbiah (Principal of the Agricultural School, Cawnpore) issued (*Dept. Agri. U. Prov. Bull.*, 1901, No. 13) a complete review of all past experiences, and, commenting on that, Moreland observes, "It will be seen that attempts to make *gür* by the ordinary methods were complete failures, and it seems probable that this must be the case, as unrefined beet-sugar made in Europe retains certain organic matter which gives it an unpleasant flavour." It is, therefore, urged that "if beet is grown it will be on the central factory system, the cultivator receiving an advance and engaging to grow beet, the roots to be taken to the factory." [*Cf. Mukerji, Handbook Ind. Agri.*, 1901, 388-9.]

Palmyra.

orassu *abe fier*, the Palmyra Palm or *brab* tree of Bombay and Madras Presidencies. This is one of the sources of the substance known in Indian commerce as *jaggery*. Rheede (*Hort. Mal.*, 1686, i., 11-13, tt. 9-10) alludes to the present species of palm as being tapped for its sweet juice (*ras*), but says nothing of its sugar. It affords much of the sugar of South India,

especially Tinnevely. Buchanan-Hamilton wrote in 1807 that the *jaggery* of this palm was more esteemed in Mysore than that of the date-palm. It is also largely utilised as a source of sugar in Burma (see p. 170).

Caryota urens, the Indian Sago-palm or Bastard Sago, is the chief source of the palm-sugar of South Ceylon and to some extent of Bombay (see p. 287). Indian Sago-palm.

Cocos nucifera, the Coconut Palm, is the species most extensively used in Madras as a source of palm-sugar. Garcia de Orta (1563) speaks of the *sura* or toddy which, fermented, yields *arrack* and vinegar, or from which, when thickened in the sun or by heat, they make *jagra*, the best kind of which comes from the Maldives. Rheede (*l.c. i.*, 1-8, tt. 1-4) speaks of "*jagra*" (sugar) made from the juice with the aid of lime, the mixture being boiled until it thickens, when a red-coloured sugar is obtained (see pp. 362, 932). Coconut. Lime.

anna—some thirteen or fourteen plants in India are known to yield, under the parasitic influence of insects or otherwise, a sweet fluid called *manna*. This is regularly collected and, like honey, enters more largely than sugar into the pharmaceutical preparations of the Hindus (see *Bamboo*, p. 111, and *Honey*, pp. 128-9). [*Cf. Garcia de Orta, 1563, Coll., xxxiii.*] D.E.P., v., 165-7. Manna.

Phoenix sylvestris, the Common Date-palm, is perhaps the most important source of palm-sugar in India. In fact, the plant is fairly extensively cultivated in Eastern Bengal as a source of sugar. In Mysore it is also important, more so than either the palmyra or the coconut sugars (see p. 886). Date.

Saccharu officinaru, the Sugar-cane—the subject of the present article. Sugar-cane.

Sorghum vulgare, the Sugar-Sorghum or *imphee* (see p. 1041).

Vitis vinifera, the Vine. According to Aitchison (*Edinb. Bot. Soc. Trans.*, 199), also Le Mesurier (*London to Bokhara*, 133), the juice of the grape is used in Afghanistan to make syrup, and in Merv refined sugar. Vine.

Zea ays, Indian-corn or maize, often yields sugar in its stem, like that of *Sorghum* and *Saccharum* (see p. 1138). Maize.

Many substances other than those enumerated are known to afford sweet fluids, but are for the most part utilised in the manufacture of alcoholic beverages or sweet sherbets only, while others, such as indigo-sugar, are at present put to no economic purpose whatever. The *mahua* flowers (see p. 118) and the pineapple (see p. 69) are the best-known substances available in India from which a sweet juice may be prepared (if the grape be excluded from consideration), or which are actually utilised in the production of alcoholic beverages. Honey is largely traded in all over India. *Halwa* (a sweetmeat, much like "Turkish-delight") is said to be prepared from camel's milk and honey, and is brought into India from Afghanistan and ports on the Persian Gulf. weet Fluids.

SACC A U A U DI AQ UM, *retz.*; *Fl. Br. Ind.*, vii., 119. This embraces the following:—*S. ciliare*, *Anderss.*, *S. exaltatum* (*Munja*) and *S. procerum* (*Sara*) of Roxb. It is the *sara* of the classic authors of India, and bears the following vernacular names—*sara*, *sarkanda*, *sarkara*, *ramsar*, *sar*, *ser*, *mūnja*, *ikar*, *patā*, *war*, *palwa kanda*, *darga*, *gundra*, *ponika*, etc. Is met with throughout the plains and lower hills and distributed to China. In the Panjāb it often covers large tracts of country and is frequently planted in lines or dividing hedges, especially in low-lying localities subject to periodic inundation. D.E.P., vi., pt. ii., 1-2. ara and Munj.

History.—Sir William Jones (*Sel. Ind. Pl.*, in *As. Res.*, 1795, iv., 247-8) says: "This beautiful and superb grass is highly celebrated in the *Purānas*, the Indian God of War having been born in a grove of it, which burst into flame; the gods gave notice of his birth to the nymph of the Pleiads, who descended and suckled the child, thence named Carticeya. The *casā*" (*kāsā* or *kāns*) "vulgarly *casia*" (*S. spontaneum*) "has a shorter culm, leaves much narrower, longer and thicker hairs, but a smaller panicle, less compounded, without the purplish tints of the *sara*: it is often described with praise by the Hindu poets for the whiteness of its blossoms, which give a large plain, at some distance, the appearance of a broad river. Both plants are extremely useful to the Indians, who harden the inter-nodal parts of the culms, cut them into implements for writing on their polished paper. From the *munj*, or culm, of the *sara* was made the *maunji*, or holy thread, ordained by Menu to form the sacerdotal girdle, in preference even to the *cusa-grass*." For its use in the treatment of vinegar, see p. 1110. Sacred Grass.

Munj FIBRE is obtained from the leaf-sheaths; the blades are the *sar* or *sara* used in thatching houses and as a paper material; the contained flowering stem is the *bind* or *vind*; the panicle or flowering stem is the *sirki*, *til* or *thili*, used in thatching boats, carts, etc.; *sentha* or *kana* is the lower, stronger portions of the Pens. Holy Thread. Munj Fibra.

Paper.

Delhi Mats.

flowering stem, used in the manufacture of chairs, stools, tables, baskets and screens; and *tilak*, *tilon* or *ghua* are names that denote the flowers. Some of these names, such as *munj* and *sara*, have been supposed to denote the products of different species, instead of different parts of one and the same plant, hence has originated much of the confusion that prevails. *Sara* is used in paper-making and *munj* as a textile fibre. The much prized *munj* is strong, elastic and has a wonderful power of enduring moisture without decaying. It is extensively employed in the manufacture of cordage, ropes, the famed Delhi mats, and in the preparation of baskets, etc. *Munj* mats are reported to be proof against white ants, but are hard on shoe-leather, harsh to the foot and fatiguing when walked on for any length of time. These are largely produced in Allahabad, Agra, Delhi, and are traded in all over India, and within recent years have begun to find their way to Europe (see *ats*, etc., p. 777). In the early spring the old grass is often fired, when shortly after a crop of young leaves is produced from the stools, which is much valued as fodder.

D. P.,
vi., pt. ii.,
11-2.

Káns.

S. SPONTANEUM, Linn.; *Fl. Br. Ind.*, vii., 118-9. This has received various names, such as *S. egyptiacum*, Willd., *S. bengalense*, Ham. (*Boga*, *Casi*, *Lota* and *tennis*), *S. canaliculatum*, Roxb. It is the *kásá* of Sanskrit, and in the vernaculars the *káns*, *kosa*, *kagara*, *kus*, *kás*, *kánsi*, *rara*, *jasha*, *padar*, *rellu-gaddi*, *billu-gaddi*, *thetia kyn*, etc., etc. (seep. 1122). Is contrasted with *S. arundinaceum* in the above.

Seasons.

Thatch.

Fodder.

Throughout the warmer parts of India and Ceylon, ascending to 6,000 feet in altitude. Is most at home in damp low-lying land, where it throws up flowering stems often 12 feet in height. Is gregarious, the snowy white pubescence which surrounds the base of the spikelets rendering it a conspicuous feature of the vegetation when at all prevalent. It flowers soon after the close of the rains. Owing to its vigorous growth it is difficult to eradicate, hence often becomes a troublesome weed, especially in the tea plantations of Assam and Bengal. [*Cf. Batchelor, Agri. Journ. Ind.*, 1906, i., pt. ii., 152-8.] The grass is large and coarse and is used mainly as a thatching material. The leaves, sheaths, etc., are twisted into rope and worked up into mats, but are inferior to *munj* for these purposes. As a fodder plant it is usually regarded as superior to the former species, and is specially valued for feeding buffaloes. The culms are also much more highly prized for the manufacture of Native pens. [*Cf. The Bower Manuscript* (Hoernle, transl., 1893-7), 96, 106, 122, etc.]

ugar-cane.

Vernacular
Names.

. offici rum, Linn., *Sp. Pl.*, 1753, 54; *Fl. Br. Ind.*, vii., 118; Rumphius, *Herb. Amb.*, 1750, v., 186-91, t. 74; McFadyen, in Hook., *Bot. Misc.*, 1830, i., 95-115, t. 26; Roxb., *Fl. Ind.*, i., 237; Köhler, *Med.-Pflanzen Atlas*, ii., 169; Hackel, *Monog. Androp.*, in De Candolle, *Monog. Phaner*, vi., 111; Krüger, *Das Zuckerrohr und Seine Kultur*, 1899; GRAMINEÆ. The Sugar-cane, *ukh*, *úk*, *us*, *ikh*, *ik*, *ák*, *aku*, *ikhari*, *rikhu*, *serdi*, *sheradi*, *ganná*, *ghenra*, *nai-shakar*, *kumad*, *kúshiar*, *púri*, *cheruku*, *charhi*, *khabbu*, *karumbú*, *karnipa*, *tebu*, *keyan*, *kyán*, etc., etc. The majority of these names denote the cane-plant, others doubtless the sugar. The selection given is, however, fairly representative of the names in current use in India. In the Malay Archipelago the cane is known as *tabu* and in China as *kan-che*, a word believed to be derived from the Sanskrit *khanda*, a name for sugar. As a cultivated plant cane is widely distributed in India and numerous very distinctive forms exist, some of them known from the earliest historic times, others introduced quite recently.

Crystallised.

History.—The Sanskrit name for the plant is *ikshu*, of which the modern corruptions are *ikh*, *ukh*, and *unkh*. Mention is also directly made of the sugar-cane in the *Atharvaveda* (Bloomfield, transl., xlii., 100, 277). The name *sarkarā* is similarly given by the very earliest Sanskrit writers for white sugar, and it originally denoted "grit" or "gravel," hence its special signification as crystallised sugar. The name *khanda* (an ancient name for sugar), the root of which means to crush, may be considered to denote sugar from the sugar-cane rather than from palm-juices, where no crushing in any form is pursued. By modern usage, however, it became restricted, like its English derivative "candy," to a special form of crystallised sugar—the sugar-candy (*sarkar-khandi*).

Candy.

In the same way the word *guda* or *gula* indicates a "mass" or "ball," hence its special application to thickened sap—the modern *gúr* or raw sugar or molasses, *Gúr.* as also the balls of sugar that were used as coins in village commerce.

The ancient name for Bengal is *Gaura*, a word supposed by some to have denoted the country of *gúr*, and hence it has been affirmed that in Bengal originated the art of sugar manufacture. This seems highly improbable, since *guda* occurs in the classic works of India, prior to the Aryan conquests of Bengal. Lastly the name *jaggery*, which to-day is used with the special signification of palm-sugar or palm-molasses, is but a modern corruption of *sarkarâ*, first into the Malayal *chakkara*, then into the Portuguese *jagara*, *jagra*. Barbosa (*Coasts E. Africa and Malabar*, 1516, 59) speaks of "the sugar of palms which they call *xagara*." João de Barros (*Decadas de Asia*, 1553, iii., lib. iii., cap. 7) mentions the *jagara* made from the cocoanuts exported from the Maldives. Cæsar Frederike (1567) calls it *giagra*. Rheede, in the passage alluded to in connection with the cocoanut, calls it "*iagra*," and Buchanan-Hamilton (*Journ. Mysore, etc.*, 1807, i., 157-8; ii., 101; iii., 145-6, etc., etc.) uses the word *jagory*. A knowledge of *tari* wine seems ever so much older than of sugar prepared from the same juice. *Jaggery.* Megasthenes (320 B.C.) alludes to the value of the *tala* trees to the people of India (*Indika of Arrian* (McCrindle, transl.), 199; see also *alt Liqueurs*, p. 757). But Eratosthenes (223 B.C.) is perhaps alluding to sugar-cane when he tells us that "the roots" were sweet to the taste both when eaten raw and boiled.

Lucan (A.D. 65) refers to the sweet juice expressed from reeds (*tenera arundo*). Paulus Aegineta (Adams, transl.), iii., 246, in the 7th century, speaks of the sugar brought from "Araby the Blessed" as being less sweet than honey. Unmistakable reference is made to sugar-cane as cultivated on the shores of the Persian Gulf during the 9th century. "The crusaders found sweet-honeyed reeds in great quantity in the meadows about Tripoli, which reeds were called *sucra*." Galt, who published a history of sugar, says it is certain that in the year 1148 it was largely cultivated in Sicily and that the Venetians traded in it, but he adds, "I have met with no evidence that the Saracens carried it from India to Sicily." Sanutus, who wrote of 1306, observes that in the countries subject to the Sultan, sugar-cane was produced in large quantities, and that it was likewise carried to Cyprus, Rhodes, Sicily and other places belonging to the Christians. *Tari.* Cultivation Mentioned.

The Greco-Roman world had a very distorted idea of the origin of sugar. It was a kind of honey obtained from canes or *mambas*. In Hebrew writings there is no indication of a knowledge of sugar, so that it was not cultivated in Arabia and Egypt prior to the Jewish captivity at Babylon. The Chinese do not appear to have known of sugar from very ancient times. Bretschneider says that he has not been able to discover any allusion to it in the most ancient books. It is first mentioned, he adds, in works that date from about the second century B.C. According to the *Pent Sao*, a man was sent, about 627 A.D., from China to Bihar to learn the art of refining sugar. Marco Polo (*Travels*, 1290 (ed. Yule), ii., 313) visited India, and gives full particulars of the coast towns of the south and west. Of Quillon, he says "their wine they make from palm-sugar." But Polo does not definitely mention sugar, or rather sugar-cane, until he reaches China. Of Peking, he remarks, "enormous quantities of sugar are made," and this "brings many merchants who traffic about the Isles of the Indies." In a footnote, Sir Henry Yule explains that there is still a great deal of sugar grown and made about Fuchau; indeed all the fine Chinese sugar-candy is produced at Fokien. If, therefore, this reference to Chinese sugar denotes sugar-cane, it is the only one in Marco Polo's record of his great explorations that can be so interpreted.

In one chapter Polo alludes to Bengal, but it has been shown that he never himself visited Eastern India and that his notions of Bengal were so imperfect that the particulars he affords regarding sugar cannot be accepted as necessarily denoting an ancient knowledge. Ramusio (in his edition of Polo) says the Chinese were taught the art of refining sugar by some men from Cairo who happened to be at the Court of the "Great Can" (*Purchas' Pilgrimes*, iii., 101). Sir Hugh Willoughby (about 1554) speaks of "such number of Ingenios for sugar" seen near Peking (*Purchas, l.c.* 270). Most of the 15th and 16th century travellers in China mention sugar as being so good and cheap. It is commonly stated that Vasco da Gama (who doubled the Cape of Good Hope in 1497) relates that a considerable trade in sugar was at that time carried on from Calicut—the then capital of Western Indian commerce. John Leo makes a similar statement regarding Nubian

China.

Indian Sugar.

Machinery.

sugar during 1500 A.D., and other travellers shortly after the time indicated discuss the sugar of India. Thus, for example, Varthema (*Travels*, 1510 (ed. Hakl. Soc.), 163) explored the west coast and furnished many details of the trade and industries of Calicut. He gives a full account of its fruit trees, and says of the cocoanut that it is the best tree in all the world. He describes its wine and sugar and tells of the monkeys stealing the former. But he makes no mention of sugar-cane. Of a town in North Kanara, identified with Sedasevaghur (which he calls Bathacala), he observes that it possesses "a great quantity of sugar," but from the previous account of the Calicut sugar it may be presumed this also was palm-sugar. It is somewhat strange that Garcia de Orta should make no mention of sugar-cane, and it is certainly most singular that Baber (*Memoirs*, 1519 (Leyden and Erskine, transl.), 326-7) should furnish many interesting details of the date, the cocoanut and the palmyra palms, but make no mention of the sugar prepared from them nor of the sugar-cane fields of India. He speaks of the juice of the palms being called *tari*, and of its being drunk both fresh and after it had fermented. But he admittedly describes only the plants and animals seen in Hindustan which were different from those of his own country—Ferghana and Bokhara. He accordingly apologises for having mentioned the date-palm, which was not confined to Hindustan. It has already been pointed out that Rheede, the earliest and even to-day one of the most accurate of Indian botanists, while describing and figuring *Borassus*, should make no mention of its sugar, though he describes the sugar of the cocoanut; and even still more curious is it that he is silent as to sugar-cane. The *Ain-i-Akbari* (1590, Blochmann, transl., 69) fortunately gives us full particulars. "Sugar-cane, which the Persians call *naishakar*, is of various kinds, etc., etc." Linschoten has much to say regarding sugar (*sura*), but his reference to sugar-cane would appear to have confused it with bamboo (*mambu*, as he calls it), the old error that descended from the classic times of Greece and Rome, so that it is possible even Linschoten had not personally examined the plant. Thevenot (*Travels in Levant, Indostan, etc.*, 1687, pt. iii., 26) mentions the cultivation of the sugar-cane in Surat.

There would seem little doubt that sugar-cane cultivation originated in Southern Asia, if not in India, but it has never been satisfactorily proved to have been met with wild in India or anywhere else, and is accordingly known purely and simply as a cultivated plant. Loureiro would, however, seem to think it was indigenous to Cochin-China (*Fl. Coch.-Chin.*, i., 52), but perhaps with no greater justification than the statement of its having been found wild in the Car-Nicobar island. The mention of sugar, by European travellers to the west coast of India, almost invariably denotes palm-sugar, and as that part of India was first reached and explored, it seems likely that an undue importance has been given to palm-sugar (see remarks under Trade). It is, however, to say the least of it, very surprising that the early botanists who deal with the plants of India make no mention of sugar-cane. Thus, for example, Rheede (1698 A.D.) gives a brief account of one of the naked-seeded sorghums, but says nothing of its yielding sugar. Rumphius (1750) tells us, however, that the white-seeded sorghums often have the stems so sweet that they are regularly chewn for their sweet juices, but adds that sugar is never made from them as from sugar-cane. In a further passage he gives full particulars regarding sugar-cane cultivation in the Dutch colonies, but ventures no opinion as to the home of the plant. Miquel, Hasskarl and Blanco make no mention of wild sugar-cane in Sumatra, Java or the Philippine Islands. Crawford tells us that he failed to find it in the Indian Archipelago. It seems fairly certain, however, that the Muhammadans were conspicuously identified with the extended cultivation of both cotton and sugar-cane. After the Muhammadans, the Portuguese were perhaps the people most closely associated with the early distribution of sugar-cane cultivation. In 1419 it was taken to Madeira from Sicily (*Purchas' Pilgrimes*, i., 5), and there would seem every reason for believing that this was its first appearance on the islands of the Atlantic. Sloane (*Nat. Hist. Jam.*, 1707, i., 108-9), while describing sugar-cane and the manufacture of sugar, dwells especially on the necessity of adding an alkaline salt or "temper" to the boiling liquid, to facilitate the formation of the crystalline article. But although the story of the Muhammadan influence is generally accepted, it is somewhat curious that Browne (*Hist. Jam.*, 1789, 129-33) should have regarded the plant as a native of the Canary Islands. He appears to have thought it existed there before its introduction by the Spaniards and the Portu-

guesse to the mainland and islands of the west coast of Africa. From Madeira it apparently was taken to Brazil, but at a very early date, for Magellan speaks of finding it there in 1519 (*Purchas, l.c.* 34). From Brazil it was carried to St. Domingo and Barbados. Of the last-mentioned island, Ligon (*Hist. Barbados*, 1657, 84 *et seq.*) will be found to give a detailed account. He describes all the noteworthy fruits of the island, but of sugar-cane observes, "There is one brought thencefrom as a stranger, from beyond the line, which has a property beyond them all, and that is sugar-cane." He landed in the island 1647, and found sugar-cane cultivation but little understood, though the plant had been introduced from Brazil and an "Ingenio" for manufacturing the sugar had been set up. When he left the island in 1650 the manufacture had been greatly improved, and they had discovered the period necessary for the full maturity of the canes, namely fifteen months. They had also learned to manufacture "lump sugar," "but not so excellent as they make in Brazil." Towards the close of the 18th century the French colonists of St. Domingo carried the cane to Louisiana. These brief references to the West Indies may suffice to convey the opinion that it is there an exotic, and it may not be far from the truth to add that it was the necessity for labour in sugar-planting that gave origin to the slave traffic.

England.

Present
Cultivation.

Flowering.

Fertile Seed.

John Leo, who began his explorations of Africa and Egypt about 1492, describes the sugar of Morocco and of Egypt, which appears even then to have been made from sugar-cane. Similarly Richard Jobson describes the sugar-canes of Sierra Leone and Gambia in 1620. Forster (*Pl. Esc.*, 1786, 77) speaks of sugar-cane as grown in Polynesia for the children: in Tahitian it is known as "To." It is recorded that the Otaheite cane was introduced into Trinidad and Martinique in 1782. The date when sugar (from sugar-cane) first reached England has not been definitely ascertained. We read of its being carried from St. Lucas in Spain to Bristol in 1526. In 1503 two ships arrived at Camperre laden with Canary Island sugar, and a century and a half later the supply from the West Indies and Brazil might be said to have been fully established and become almost a necessity on every breakfast table in Europe. At the present day sugar-cane is grown throughout the tropics and sub-tropics, and even into the warm temperate tracts, especially in the West Indies, Mauritius, British Guiana, etc., and at Malaga on the Mediterranean coast of Spain. It requires a hot, moist atmosphere alternating with periods of dry weather. It rarely flowers and fruits, so that cultivation is almost exclusively by cuttings. These are called "plants," and usually consist of two or three upper joints of the cane, the severance being by a clean cut immediately below a joint.

Hughes (*Nat. Hist. Barbados*, 1750, 244-52, t. 23, f. i.) alludes to the flowering of the canes in Barbados, and gives full particulars of the cultivation and methods of manufacture pursued. But with regard to the fruiting and the production of fertile seed, there is no definite record of this fact having been utilised for a century later. Rumphius says, "It never produces flowers or fruits unless it has remained several years in a stony place." Roxburgh remarks, "Where wild I do not know: I have never seen the seed." But in the West Indies, about 1858, it was recorded that seedling canes had been observed to spring up around the stems (or stools) of canes that had "arrowed" or flowered, from which circumstance it was believed and oft reiterated, that the sugar-cane actually did produce fertile seeds sparingly, though more copiously under certain climatic and soil conditions. [*Cf. Joret, Les. Pl. dans L'Antiq.*, etc., 1904, ii., 266-9.]

Varieties and Races of Sugar-cane.—The diversity met with would appear to have been brought about primarily by selection of sports and variations as manifested in adaptation to environment; through the study of yield of sugar to the acre; the observation of freedom from disease, etc., as also by the direct cross-breeding of the stocks thus procured and matured. Leather defines a good cane as one which will yield 70 per cent. of juice in the mill, afford 15 per cent. or more of cane-sugar, and possess not more than 17 per cent. of glucose. In the *Dictionary* the effort was made to divide the canes met with in India into two great sections:—(a) *Introduced Canes*, and (b) *Indian Canes*. Without going into needless details regarding the various foreign canes known to be cultivated in India, the following particulars may be furnished:—

1. *auritus* C e.—This appears to have been introduced into India from

D. .P.,
vi., pt. ii.,
41-7 .
Varieties
and Races.

auritus.

Mauritius about 1838 (if not much earlier) and was so named in consequence, but is in reality the yellow-violet cane of Java. It is said to excel the red Bombay cane both in size and quality, and to yield one ratoon crop or sometimes two (when grown on rich soils), but as the roots get considerably above ground it requires subsequent surface dressing.

Otaheite.

2. Otaheite or Yellow d Straw-coloured C e.—This was introduced into India about 1840, and became widely distributed, especially in Eastern Bengal and Assam. It is questionably distinct from the Mauritius canes of many plantations. The leaves are broad, pale green and droop considerably, especially on nearing maturity. It shows a marked tendency to arrow, especially if grown under the influence of sea-breezes. It has not proved a success in India, however, as it demands the finest soils, the most thorough agricultural methods, and perfect protection; is withal very liable to disease and to the attacks of white ants. According to many observers it rapidly deteriorates in India.

Bourbon.

3. Bourbon Cane.—This is by some persons supposed to have been originally discovered on the coast of Malabar, and from there to have been carried to Reunion, improved, and then returned again to India *via* the West Indies. By other writers both this and the straw-coloured Otaheite canes came originally from Madagascar, while still other writers affirm that the Bourbon cane is one and the same as that often called the Singapore.

Batavian.

4. Batavian Canes.—There are several distinct forms, such as the violet cane, of which Sir John Lefroy wrote in 1794, "The Batavian canes are a deep purple on the outside." Wray says the yellow-violet and purple-violet or Java canes, as also the transparent or ribbon canes, all belong to this type. The yellow-violet differs from the Bourbon and Otaheite in being smaller, less juicy, considerably hardier, slower of growth and with the foliage darker and more erect. When ripe it is usually of a straw-colour with the rind thick and the pith hard, but its juice is rich and tolerably abundant. The purple-violet, on the other hand, is fully as thick as the Bourbon, and has the joints from three to six inches long. The leaves are darker green than the yellow-violet, and it yields a juice richer in sweetness than almost any other cane; but it is hard, difficult to grind, and affords but a low percentage of juice. The transparent ribbon-cane is of a bright yellow, with a number of blood-red streaks; its leaves are like those of the yellow-violet, but more erect. In Jamaica it is generally planted on light sandy soils, where no other cane will thrive.

Transparent
Ribbon.

Canes Eaten.

It yields a fair quantity of juice of excellent quality. This cane was introduced into India (*via* Bourbon) in 1838, from which circumstance it came to be called "striped Bourbon." Mr. Kobus, who visited India in 1891 to endeavour to procure fresh stock for the Java plantations, recognised the *paunda* canes of India (the canes grown specially to be eaten, and not used in the manufacture of sugar) as identical with the canes grown by the Dutch for sugar manufacture. The *ukh* and *ganna* (the kinds specially grown in India for sugar manufacture) were previously unknown to Kobus, and he accordingly took back with him a large supply of these. It thus seems highly probable that most of the edible canes of India have been developed from imported stocks, such as those briefly enumerated above.

China.

5. China Canes.—This is the *Saccharum sinensis*, which Roxburgh regarded as distinct from the indigenous canes of India. The distinction that he made has not, however, been upheld by modern writers, namely in the leaves being flatter and the margins more hispid. The flowering panicles, Roxburgh says, are ovate in general outline, with simple or compound verticillated branches. The Indian forms he separates as having panicles spreading, the branches alternate, decompound, and the corolla one-valved (instead of having the two valves on the same side, seen in the Chinese canes). These canes were introduced into the Botanic Gardens of Calcutta in 1796. Most writers, who experimented with the China canes shortly after their introduction, reported that they were hardy and prolific, not liable to attack by white ants nor jackals, and moreover able to withstand the hot weather better than the indigenous sorts. These opinions are vouched for repeatedly in the *Journal of the Agri.-Horticultural Society of India*, but it is feared that if the original stock of China canes survive to this day at all, the plants have very possibly been largely merged into the indigenous forms and their origin mostly forgotten.

Introduced
into India.

in apore.

6. Singapore C es.—As already affirmed, the more important of these seem to be identical with some of the Batavian and Bourbon canes. Wray gives eight different kinds met with in Penang, Singapore and Malacca. The prin-

cipal is the Selangore cane, known as *tibbu bitong berabu* (= the powdery dark cane) or *tibbu cappor* (= the chalk cane) of Singapore and Malacca. These names are due to the presence of a large quantity of white resinous substance on the stalk. By many writers this is spoken of as the finest cane in the world. But in the Straits it is often called the China cane, because grown by the Chinese settlers in the Straits before the Europeans commenced cane-planting. The leaves are very broad and deeply serrated on the edges, very dark green in colour and firmly attached to the cane. The cane-itch is usually very prevalent on this plant. The *tibú-liut* (or clay cane) seems to be identical with the Otaheite of most writers. The *tibú tiliur* (or egg cane) seems peculiar to Taune, one of the New Hebrides. The leaves are smooth and the stems bulge between the joints to such an extent as to have suggested its name. The leaves are shed as they ripen, and the stem becomes so brittle that it breaks readily. It is prolific and easily cultivated. The juice is copious and rich in quality. The *tibú clam* or *obat* is the black or medicine cane of the Malays. It is a small cane of a rich purple colour.

Finest Cane
in the World.

Black Cane.

The red-purple cane of Singapore is generally accepted as the stock from which has been developed the red canes of Bombay. This is interesting in the light of the other suggestions and opinions which point to Bourbon and the straw-coloured Otaheite canes being identical, and to their having originated from Malabar. Thus the early European sugar-planters appear to have obtained their stocks from Malabar, Batavia, Madagascar and the Straits. Hence it may be added, in conclusion, that nothing has been discovered in philology, botany or history that seriously upsets the hypothesis that all the forms of sugar-cane emanated from a common species, which was very probably originally a native of India and perhaps also of the tracts adjacent to India.

Red-purple.

7. **Indian Canes.**—It has been pointed out by Benson and others that foreign canes introduced into India rapidly manifest a decline in the percentage of sugar-yielding juice. The crop of cane continues high, but the merit in sugar-production declines. This fact has led naturally to greater faith being placed in the improvement of Indian stock than in the acclimatisation of foreign canes. Commenting on the Madras canes, Leather observes that “undoubtedly some of the cane which is at present grown in the Madras Presidency is second to none in the world.” A movement has, therefore, been started to study the Indian canes critically by growing them side by side at test farms. Saiyid Muhammad Hadi, having devoted considerable attention to the study of the canes of the United Provinces, published a valuable work designated “*The Sugar Industry of the United Provinces of Agra and Oudh*” (1902), and assorted the canes there described and illustrated into three groups as follows:—

Indian
Indigenous
Canes.
Decline in
Sugar Yield.

Group I. Ukh Canes.—These are the most numerous and most extensively cultivated of all races. They are grown entirely for the production of sugar. The majority have a fairly hard, firmly adhering skin, which cannot be detached with a knife beyond the joints. Stems (canes) small, thin, erect, reed-like, thickest a little above the middle, mostly lemon-green in colour, with age becoming pale yellow or, in a small subgroup, blotched with red. Leaves narrow, small, dark green and soft. Aerial roots proceed as a rule from but a few of the lower joints. The internodes are short, only slightly constricted at the joints, and often possess a distinct central cavity that is even surrounded with strong fibrous cords. Buds small, depressed.

Classification.

Ukh Canes.

Description.

These, Hadi refers to the following sections:—(a) *canes other than yellow*. Of this nature he forms three series as follows:—(1) *dhawl* canes, of which he figures and describes seventeen different kinds. (2) *matna* canes, of which he shows ten kinds. And (3) *kuswar* canes, which he refers to twelve different kinds. Then under (b) *the red ukh canes*, he places the *chin* or *chan* canes, of which he describes six different forms.

Races.

Races

Hadi regards the *paunda* canes as foreign, but accepts the *chin* as indigenous. It seems possible, however, that some of these may in reality be the survivals of the Chinese canes largely experimented with in these provinces nearly a century ago.

Ganna
Canes.

Description.

Group II. The Ganna Canes.—Except in a few districts these are grown almost exclusively as edible canes, especially in districts where the *paunda* canes cannot be successfully raised. They are usually taller and thicker than most of the races of *ukh* canes, and have longer and broader leaves. The skin is generally hard, but easily removable. The pith is always distinctly softer than in the former group. The central cavity and filaments are also absent and the canes are juicy, though not very rich in sugar. The aerial roots are more largely produced, and the buds are large and more conspicuous than in the *ukh* canes. But the sugars manufactured from them are inferior in colour. Lastly, they are very liable to fungal diseases, such as “red smut” (*Trichosphaeria Sacchari*), and are readily attacked by wild animals and white ants.

Fungal
Disease.

Races.

The best-known examples of this group are known as *agaul*, *merthi*, *dikchan*, *pansáhi kálá ganná*, *katára*, *baraukha*, *tanká* and *ghorara*. Most of these names denote introduction from one district to another, such as Gagaul (*agaul*), a village in Meerut; and *merthi*, Meerut—but Hadi accepts the majority at least as being indigenous to India.

Paunda
Canes.Edible
Canes.

Description.

Group III. Paunda Canes.—These are the acclimatised canes proper, that is to say, those admitted by the people to be of foreign origin, such as the Mauritius, Otaheite, Bourbon, Batavian, China, Singapore, etc., discussed above. They are grown almost entirely for chewing, except in one or two localities where they are used for sugar manufacture. Generally speaking, their cultivation is confined to the vicinity of large towns where a ready market may be obtained. High cultivation, involving heavy expenditure, is an essential feature for the growth of these canes—hence they are more profitable as edible canes than as sources of sugar.

Races.

They are tall plants, very thick, with hard skin (easily removable), and soft, fleshy, central solid stems. The leaves are proportionately long and broad, and aerial roots more abundant than in any other canes, but their buds are proportionately small. Many of them have been so long under cultivation in India that they have had local names assigned to them. The best-known examples of this are: (1) Madrasi or *thun*; (2) Bombai (red cane of Bombay); (3) Saharanpuri; (4) *lal* or *kala ganna*; (5) Banarsi; (6) Burmi; and (7) Poona *paunda*.

Standard in Description.—Mollison and Leather furnish a diagram showing in outline four forms of cane, and suggest the desirability of future writers accepting these as comparative standards. They furnish particulars of 46 canes, but of 11 they have omitted to say to which type they belong, and of 9 more they are apparently not quite certain themselves. The proposed classification would thus seem by no means a very satisfactory one. In type (A) the joints are constricted but the cane not materially swollen, whereas in (C) the joints (nodes) are constricted and the internodes distinctly swollen. These would seem to correspond very largely to both the *ganna* and *paunda* canes of Hadi's classification. The following are the (A) canes of Mollison and Leather:—*kali-jadi*; *deo-gadi*; Green Mauritius; *rasdali* (*rasali*, the juicy); Yellow-green of Bijapur; Purple Mauritius (imported in 1893), the *rámrasdáli* of Kanara; Streaked cane of Dhárwár and Belgaum; Madr i

Chief
Indian
Canes.

paunda (of Sitapur, Barabanki, Bareilly, etc.); *kajli* (of Bardwan); and the *puri* (of Bardwan). (C) canes are: the *khajuria* or *meva* (of Surat); Malabari (of Surat); the *mahim* Yellow-green or Poona *pundia*; *samsara* (of Dumraon); and the Saharanpuri (of Cawnpore and Bareilly).

The (B) and (D) canes of this classification seem to correspond to the truly indigenous canes of India which Hadi groups under the most general Indian name *ukh*. Of the former the following may be mentioned:—*vansi* or Bamboo or *betta kabbu* (of South Maráthá country); *hullu kabbu* (*hullu* = grass, and *kabbu* = sugar-cane) (of the South Maráthá); *sanna* (= small) -*bile* (= white) -*kabbu* (of Khánápur and South Maráthá); *mungo* (of Dumraon); *dhaul* or *dhaur* (of Cawnpore, Bareilly and Shahjahanpur); *matna* (of ditto); and *rakra* (of Shahjahanpur).

The (D) canes are as follows:—*pansabi* (of Behea); *khari* (of Dumraon and Bardwan); the *dikchan* (of Cawnpore and Shahjahanpur); and the *munga* (of the same place).

Lastly, the (E) canes of Mollison and Leather seem to correspond closely with the coloured *ukh* canes of Hadi. The examples given by the former authors are *bhuri*, *phojbhuri* and *songadi* (of Surat); the Purple cane (of Bijapur, Bassein and Thana); and the *kare kabbu* (*kare* = black) (of Belgaum, Khánápur and Dharwar).

I have enumerated the chief canes mentioned by Mollison and Leather, and not those given by Hadi, because the former are applicable to a wider area, and at the same time, so far as the United Provinces are concerned, correspond with many of those given by Hadi. The *Imperial Gazetteer* (iii., 39) says the canes of India may be broadly grouped into (a) thick, juicy, soft kinds which ordinarily require very liberal cultivation and irrigation, and (b) thin, hard, less juicy canes which, with well-distributed rainfall, succeed with less liberal cultivation and with sparing irrigation or even without any.

Juicy Canes.

eedlin Canes.—In the concluding paragraph under history, reference has been made to the flowering of the cane (p. 933). But it had long been supposed that the sugar-cane, as with some other cultivated plants propagated by cuttings, had lost the power of producing seed. Unlike the beet it was only, therefore, open to improvement by the chance occurrence of bud variations or by the chemical selection of canes individually richer in sugar.

eedling
Canes.

As a matter of fact, the sugar-cane is, though sparingly fertile, not

Natural
Seedlings.

absolutely seedless. As long ago as 1858 Parris had raised seedlings from it in Barbados, and in 1888 Bovell and Harrison, in the same island, and Soltwedel in Java, succeeded in accomplishing it. This opened the way to improvement by seminal variation, which was at once taken advantage of. Thousands of seedlings were raised from seed taken from known seed-parents, but of which the pollination was uncertain. Selection was made of those with a vigorous habit and a high saccharine content.

In 1904 Lewton-Brain succeeded in hybridising known varieties by artificial cross-pollination. It thus became possible to breed on definite lines so as to combine the desirable characters of particular races. One object would be to obtain those which would resist the disease which had led to the abandonment of the cultivation of the Bourbon cane. Seedlings produced in Barbados (about 1899-1900), and known as "B 147" and "B 208," have both been found to yield fully half a ton per acre more sugar than "Caledonian Queen," and fully three-quarters of a ton more than "Bourbon." They have, in fact, been stated to produce, under favourable conditions, fully $3\frac{1}{2}$ tons per acre, the best canes formerly grown having yielded only 2.53 tons, so that these seedling stocks showed an increased yield of 37 per cent.

CULTIVATION.

Area and Yield of Sugar-cane and Sugar.—There is perhaps no other aspect of the sugar industry of India regarding which more obscurity prevails than the Provincial and Imperial averages of yield of cane to the acre and of sugar to the cane. Moreover, returns are only available for six of the provinces, though these embrace about 95 per cent. of the sugar-cane area. The provinces covered by the official Memoranda, issued by the Director-General of Commercial Intelligence, are (1) Bengal, (2) Eastern Bengal and Assam, (3) the United Provinces of Agra and Oudh, (4) the Panjáb, (5) the North-West Frontier Province and (6) Madras. The areas omitted are (7) Bombay and Sind, (8) the Central Provinces and Berar, (9) Burma, and (10) the Native States. For the past eight years the first six provinces have shown an average of 2,307,618 acres under the crop, with a yield of 1,988,211 tons of crude sugar (*gúr*). This gives an average of 1.1 acres to the ton of crude sugar, or say one ton to the acre, provided it be accepted as safe to frame any such estimate. But it must be observed that the crude sugar of India is ordinarily a much inferior article to that indicated by the estimates of sugar-production in most other countries. Thus, for example, much of the imports by India from Java are considerably below the Continental standard. To correct

AREA AND YIELD

ACCHA U
OFFICI A U
Cultivation

Indian returns of raw sugar into the crystallised article, the proportion is $2\frac{1}{2}$ or 3 raw to 1 refined sugar. The Indian yield of cane to the acre does not appear to be ever published, so that the relative merit of the Indian stock to that of other countries cannot be ascertained.

The cane areas of the omitted provinces (7 to 10 inclusive above) can be ascertained, but not their yield of sugar. In 1903-4 and 1904-5 these came to about 140,000 acres, so that if that area be added and the proportionate figure be worked out for the outturn, the result would not materially disturb the calculations based on the six provinces only. The area returned in 1905-6 as under cane in the six provinces was 2,110,800 acres, and in 1906-7 was estimated at 2,348,800 acres. The ascertained yield was 1,725,300 tons in 1905-6, and 2,223,400 tons in 1906-7. The *Agricultural Statistics* still further show that in 1899-1900 the total area for all India under sugar-cane was 2,541,470 acres; and the subsequent figures manifest a shrinkage, right down to the returns of 1905-6, both constant and serious, though the improvement in the succeeding year is more hopeful. This may be exemplified as follows:—

Agricultural
Returns.

Contractor
of Area.

Acres.			Acres.			Actual Areas.
1890-1	..	2,758,000	1898-9	..	2,755,000	
1891-2	..	3,100,000	1899-1900	..	2,693,000	
1892-3	..	2,798,000	1900-1	..	2,522,000	
1893-4	..	2,897,000	1901-2	..	2,474,000	
1894-5	..	2,764,000	1902-3	..	2,358,000	
1895-6	..	2,930,000	1903-4	..	2,280,000	
1896-7	..	2,651,000	1904-5	..	2,244,800	
1897-8	..	2,648,000	1905-6	..	2,110,800	
Average of 8 years:—	..	2,818,250	Average of 8 years:—	..	2,429,700	

Thus, according to these returns, the area for the eight years preceding the enactment to countervail bounty-fed sugar in 1899, showed an annual average of 2,818,250 acres, and for the eight years subsequently, of 2,429,700 acres. But it is possible these returns are not very accurate for the provinces of minor production and for the Native States. They are possibly low estimates, but doubtless are relatively correct, and therefore would seem to justify the opinion that the sugar-cane acreage of India has for some years past steadily manifested a contraction.

Influence
of county-
fed u ar.

Turning now to the provincial returns, the United Provinces head the list with 49 per cent. of the total area, namely 1,228,900 acres in 1905-6 and 1,386,700 in 1906-7. Then follows Bengal with 19 per cent., or approximately half a million acres. Next Eastern Bengal and Assam with 11.2 per cent., or 201,500 acres in 1905-6 and 199,900 in 1906-7. The Panjáb, 13.7 per cent.; the North-West Frontier Province with 1 per cent.; and Madras, 2.5 per cent. of the total Indian area under sugar-cane. "In the North of India and in Bengal 20 tons of cane per acre is considered a good crop, and an outturn of $1\frac{1}{2}$ to 2 tons of *gur* per acre is obtained. In peninsular India, where sugar-cane is extensively grown under well irrigation and is very highly manured, the product is much higher, 6,000 to 7,000 lb. of *gur* per acre being an ordinary outturn. With very careful cultivation and high manuring, even double the yield has been obtained from soft varieties of cane" (*Imp. Gaz.*, iii., 41). Mollison and others have often said that the experiments conducted at the Government Farms have proved that sugar-cane can be more economically produced in India than in any other country in the world. Anglo-Indian Review, April 1903; Leather, *Effect of Change of Climate on Juice of Sugar-cane*, in *Agri. Journ. Ind.*, 1906, i., pt. iv., 412-3.]

Return in Foreign Countries.—With regard to the yield in other countries, H. C. Prinsen Geerdings, Director of the Sugar Experimental Station of West Java, gave the following yields of cane to the acre:—in Java, 36 tons; in Sandwich Islands, 33·4; in Egypt, 22; in Queensland, 16; and in Japan, 15·2. Yield of sugar in tons to the acre:—in Japan, 1·1; in Queensland, 1·6; in Egypt, 2·2; in Java, 3·6; and in Sandwich Islands, 8. These results showed the further fact, namely, tons of cane to the ton of sugar:—in Java, 7·1; in Sandwich, Egypt, and Queensland, each 10; and in Japan, 14·3.

Thus there would seem a wide range both in yield of cane to the acre and in the amount of sugar afforded by the canes produced. By high cultivation the yield of cane has been immensely increased in the Sandwich Islands, but it would seem as if the lower returns in Queensland were compensated for by the superior methods and appliances used in manufacture, since the cost of sugar-production is in Java £8 12s. 6d., and in Queensland only £8 15s., and this in the face of the startling statement of the yield being 36 tons in Java and only 16 tons in Queensland. Queensland is thus able to produce sugar at approximately the same price per ton as Java. But this question of cost of production manifests a wide range. Thus it is £8 4s. 4d. in the Sandwich Islands; Egypt, £9 10s. 11d.; Barbados, £9 15s.; Trinidad, £10 19s. 11d.; Demerara, £12 18s. 10d.; French Antilles, £14 6s. 9d.; and the United States, £18 18s. 6d. These were sums worked out a few years ago for the countries with a gold standard in currency, but it may be useful to add similar figures for the chief silver-standard countries:—Mauritius, £6 2s. 5d.; Philippines, £6 16s. 11d.; Japan, from £13 5s. 8d. to £16 16s. 10d.; Argentine, £17 14s. 11d.; and Brazil, £22 6s. 11d.

The Manchester Chamber of Commerce (*Monthly Record for Oct. 31, 1899*) discussed the yield of beet-sugar as compared with cane-sugar to the acre, with the following results:—

Beet-sugar.		Cane-sugar.	
Germany ..	1·71 tons.	Hawaii ..	3·6 tons.
Belgium ..	1·55 "	Java ..	3·2 "
Holland ..	1·29 "	Barbados ..	1·89 "
France ..	1·24 "	British Guiana ..	1·82 "
Austria ..	1·09 "	Queensland ..	1·8 "
Russia ..	0·80 "	St. Lucia ..	1·75 "
		Trinidad ..	1·54 "

Martineau gives an average of 2 tons per acre as fair for all sugar-cane production, a result which, considering the improvements already effected in the stocks and methods of manufacture and in the possibilities of the future, by no means justifies gloomy forebodings for the sugar-cane planter.

[*Cf. Board of Trade Journ.*, 1901, xxxiii., 69; *Queensland Agri. Journ.*, 1901, viii., 125; 1901, ix., 6; *West Ind. Bull.*, 1902, iii., No. 1, 46-65; *Agri. Dept. Natal Rept.*, 1902, 17; *U.S. Dept. Agri. Exper. Stat. Rec.*, 1901, xii., 742; *The American Garden* (discusses the Hawaiian yield of 10 tons of sugar to the acre).]

anures.

MANURES AND MANURING OF SUGAR-CANE.—Leather (*Agri. Journ. Ind.*, i., pt. i., 13-24) deals with the subject under the following among other headings: history, the demands of the plant from the soil, and the manures best suited to meet this strain. He suggests a division of the manures into—*first*, farm-yard, poudrette, and fish manures; *second*, oil-cakes; and *third*, bones and

saltpetre. Having given the Indian experience with each of these, he next proceeds to discuss the effect of manures on the juice. [Cf. *Sugar-cane Cult.*, in *Dept. Agri. Mad.*, 1905.]

DISEASES AND PESTS.—The blights of cane may be grouped into three Diseases. sections:—

(1) **Fungal Blights.**—Butler (*Mem. Dept. Agri. Ind.*, i., No. 3, 1-53, tt. i.-xi.) reviews the Indian literature on this subject, and furnishes much new and useful information. He describes the following diseases:—(a) Red Rot (Red Smut). Red Rot. *Colletotrichum falcatum*, Went. (b) Smut, *Ustilago Sacchari*, Rabenhorst. (c) Pine-apple disease, *Thielaviopsis ethacetius*, Went. (d) Black Rot, *Sphaeroneura adiposum*, Butl. (e) Brown Leaf-spot, *Cercospora longipes*, Butl. (f) Ring-Spot, *Leptosphaeria Sacchari*, Br. d. H. (g) Sooty Mould, *Capnodium sp.*

In a further paper, *The Selection of Sugar-cane Cuttings*, Butler (*Agri. Journ. Ind.*, ii., pt. ii., 193-201) shows the imperative necessity to avoid using diseased stock. Barber published (*Agri. Journ. Ind.*, i., pt. i., 44-8; ii., pt. i., 40) an account of the *Samalkota Sugar-cane Farm*, in which he deals with *Colletotrichum* and shows that successive canes have held favour in South India during the past forty years, each in turn only to become diseased, thus causing widespread loss. But both these authors show that such calamities might be, to some extent at least, prevented were the stock rigorously selected.

[Cf. *D.E.P.*, vi., pt. ii., 122; *Sugar-cane Diseases*, *Agri. Ledg.*, 1898, No. 13, 403-523; also Gage, 1901, No. 5, 71-95; Thiselton-Dyer, *Sugar-cane Diseases of W. Ind.*, in *Ann. of Bot.*, 1900, xiv., 609-16; Butler, *Red Rot of Sugar-cane*, in *Agri. Journ. Ind.*, 1906, i., pt. iii., 259.]

(2) **Insect Pests.**—Many writers have dealt with the pests, but more casually than systematically. Saiyid Muhammad Hadi (*Sugar Industry of U. Prov.*, 45-51) reviews the papers previously published, besides contributing largely to the subject himself. Cotes (*Ind. Mus. Notes*, i., 22-7) worked out the life histories of some of the sugar-cane pests, but it was left to Maxwell-Lefroy to furnish full details regarding the Moth-borers of the cane. The reader will find his first contribution in *The Agricultural Ledger* (1900, No. 23), but this was later on followed up by *The Moth-borer in Sugar-cane, Maize and Sorghum in Western India* (*Agri. Journ. Ind.*, 1906, i., pt. ii., 97-113). Moth-borers.

(3) **Other Enemies and Pests.**—Perhaps the most serious that has to be mentioned in this place is the root parasite *Striga lutea*. This little flowering plant injures the cane so seriously that a large percentage may often be seen to be killed by it. The only known cure is to uproot the parasite as much as possible, and to avoid growing cane on the same field for some years subsequent to a severe attack. Wild animals, such as the jackal, the boar and the rat, often do much injury to the crop, and frost or floods are alike disastrous. White ants are also very destructive (Maxwell-Lefroy, *Agri. Journ. Ind.*, 1906, i., pt. ii., 174-6; also in *Mem. Dept. Agri. Ind.*, 1907, i., No. 2, 126). For fuller detail regarding the insect and fungal pests of sugar-cane, the reader should consult the important work by Krüger (*Das Zuckerrohr und Seine Kultur*, 1899, 301-466), which, however, has more particular reference to Java.

Bengal.—The area under sugar-cane, according to the *Final Memorandum* of the Government of India for 1904-5, amounted to 633,000 acres, and the estimated yield came to 634,700 tons of raw sugar or *gür*. The *Season and Crop Report* for 1904-5 gives the areas in the various divisions as follows:—Patna, 166,000 acres; Bhagalpur, 95,800 acres; Rajshahi, 92,200 acres; Dacca, 83,700 acres; Bardwan, 79,300 acres; Chota Nagpur, 53,100 acres; Presidency, 39,400 acres; Chittagong, 17,500 acres; and Orissa, 10,800 acres. In the year following, the apparent, but not actual, decrease in area was due to 14 districts, previously returned under Bengal, having been transferred to the new province of Eastern Bengal and Assam. This leaves the normal area of Bengal for 1905-6 under cane as 421,600 acres, and for 1906-7, 423,500 acres, with a yield of 419,300 tons.

The most recent accounts of cultivation are by Mukerji and Roy. Several varieties of cane are cultivated throughout the province. According to Roy, experiments have been made, for some years past, on the Bardwan Farm with four of

tion.
Areas.

Races Grown.

these, viz:—(1) *Shamshara*, (2) *Kajli*, (3) *Poori* and (4) *Poona*. The results attained point to the *Shamshara* as the best *gur*-producing cane. The crop grows both on clayey and loamy soils, but a mixture of the two is preferable. Mukerji states that the best canes are found at the junction of old and new alluvia on the sides of streams and rivulets, where the soils are red clay loams, rich in mineral matter. As the crop is an exhausting one, it is never grown on the same land year after year. The crops it most commonly follows are pulse, mustard, potato or *aus* paddy. The best time for harvesting sugar-cane is from December to February, and the most advantageous time for planting, the month of February.

Preparation
of Soil.

In Lower Bengal the land is prepared by frequent ploughings from the middle of October to the middle of January. In most places it is also hoed, since deep cultivation is considered essential. When the soil has been thoroughly broken up, it is harrowed several times. The field is then divided into beds, by digging broad trenches, slanting from top to bottom at intervals of 40 feet, then subdivided by cross trenches 7 feet apart. Parallel furrows, at intervals of 1 to 2 feet, are now drawn along the beds, and oil-cake put into these. The plot is then well irrigated and cane cuttings placed lengthwise in the furrows and covered up. These are taken either from entire canes or the tops of canes. The latter system is said to be that pursued in the Bardwan Division, whilst the former is adopted in Bihar and Eastern Bengal. The cuttings are previously prepared by having been kept for a week or so in a cool pit—layers of cane with wet straw and ashes between. Subsequently the land is retained in a moist condition by artificial irrigation, generally given every fifth day, and when the young shoots have come above ground, the surface is well watered and hoed between the furrows. Afterwards it is occasionally irrigated and hoed, the plants being earthed up until the original furrows are converted into ridges. During the rainy season the soil is kept well drained, loose and free from weeds. From the middle of July to the middle of October the plants are tied up in clumps. Their dead leaves are removed, and oil-cake applied as a top dressing, at the rate of 4 to 5 maunds per *bigha*. The crop is harvested from the middle of December to the middle of February.

Propagation.

Irrigation.

Trimming.

Top Dressing.

Harvest.

Mauritius
System.

Cost.

In some places, especially on light soils, water-channels are not made at the time of planting, but the land is simply thrown up in ridges over the cuttings. Again, in others, after water-channels have been made, as described above, holes are dug 2½ feet in diameter and 1½ feet apart, in lines 1½ feet from one another. One cutting is put in each hole with oil-cake and water, and then covered up. This is known as the Mauritius system, because supposed to be the method adopted there, and in India is mostly used on undulating ground, but the furrow system is said to be best where irrigation is required and possible.
